1/ Data from Federal Power Commission, Statistics of Privately Owned Electric Utilities in the United States (Column 9, 10 and 11) or Steam-Electric Plant Construction Cost and Annual Production Expenses (Column 7).

2/ 1955 coal consumption. 1954 figure not available.

3/ Listed in source as "Total Assets and Other Debits."

4/ Listed in source as "Total Electric Operating Revenue."

5/ Consumption of Interstate Power Co. (Iowa) only.

6/ Includes 1/2 of coal consumption of Beech Bottom Power Co., owned 50% by Ohio Power Co. and 50% by a non-affiliated utility company. Also includes coal consumed by Ohio Valley Electric Corp., owned 37.8% by American Electric Power and OVEC's wholly-owned subsidiary Indiana & Kentucky Electric Corp. (All coal purchasing for OVEC is handled by AEP.)

7/ Listed in source as "Total Gross Earnings."

8/ Listed in source as "Operating Revenues (Electric)."

9/ 1966 consumption includes 1/3 of coal consumed at Kammer Plant, owned 1/3 by Ohio Power Co. of American Electric Power. 1967 consumption includes all coal consumed at Kammer Plant, reflecting Ohio Power's total ownership of plant as of January 1, 1967.

10/ Listed in source as "Gross Revenues."

11/ Includes equivalent for relatively small quantities of other fuels.

12/ Excludes Michigan Gas & Electric Co. Accounts not consolidated pending sale of gas properties of Michigan Gas & Electric.

13/ Includes 49,538 tons consumed for production of process steam.

14/ Includes revenue billed as of December 31, 1967, only.

15/ Listed in source as "Total Revenue."

UTILITY MERGERS AND ACQUISITIONS AFFECTING COMPANIES OPERATING IN THE MIDWEST STATES, 1955-1969 -- EFFECTED OR CURRENTLY PENDING

B. ACQUISITIONS OF MUNICIPAL ELECTRIC SYSTEMS (CONTINUED)

* Coverage includes bituminous, sub-bituminous and lignite, as in Bureau of Mines statistics.

N. A. : Not available.
-- No consumption.

1/ Listed in source as "Total Gross Earnings."
2/ Includes 1/2 of coal consumption of Beech Bottom Power Co., owned 50% by Ohio Power Co. and 50% by a non-affiliated utility company. Also includes coal consumption of Ohio Valley Electric Corp. and OVEC's wholly-owned subsidiary, Indiana & Kentucky Electric Corp. (all coal purchasing for OVEC is handled by AEP). From 1959 on, includes 1/3 of coal consumed at the Kammer Plant, owned 1/3 by Ohio Power Co. and 2/3 by a non-affiliated utility company.
3/ Listed in source as "Operating Revenues."
4/ Listed in source as "Total Operating Revenue (All Electric)."
5/ Based on "Uniform System of Accounts" effective January 1, 1961. Data for 1960 and earlier years not strictly comparable.
6/ Listed in source as "Operating Revenues (Electric)."
7/ Total annual generation. Kwh sales figure not available.
8/ No generation.
9/ Listed in source as "Gross Revenues."

VITA AND BIBLIOGRAPHY

Bruce C. Netschert
Director, Washington Office
National Economic Research Associates, Inc.

Education

B. A. (Geology), Cornell University, 1941
Ph. D. (Economics), Cornell University, 1949

Experience

1949-50 - Asst. Prof., University of Minnesota at Duluth

1951 - Commodity-Industry Analyst, U. S. Bureau of Mines

1951-52 - Staff member, President's Materials Policy Commission (prepared supply forecasts to 1975 for copper, lead, zinc, tin and rubber)

1953-54 - Consultant, Materials Area, National Security Resources Board and successor agency, Office of Defense Mobilization (assisted in formulation of stockpile and mineral industry mobilization policy)

1954-55 - Central Intelligence Agency (Branch Chief, nonferrous metals and nonmetallic minerals)

1955-61 - Senior Research Associate, Resources for the Future, Inc. (conducted research on the future supply of fuels and energy sources, including nuclear energy and solar energy, and the future supply of the major metals)

1961- - Director, Washington Office, National Economic Research Associates, Inc. (conduct and supervise research on a wide variety of subjects, with emphasis on national, regional and local supply-demand position of fuels and energy resources for various future periods; testify as expert witness on these subjects before state and federal courts, regulatory agencies and Congressional and Departmental hearings)

Professional Associations

Member, American Economic Association and American Institute of Mining, Metallurgical and Petroleum Engineers (former Chairman, Council of Mineral Economics in latter organization); Fellow, Geological Society of America; Fellow, Institute of Petroleum

Honorary Associations and Awards

Phi Beta Kappa; Phi Kappa Phi; 1961 Recognition Award, Texas Independent Producers and Royalty Owners' Association, for contribution to Energy in the American Economy (see bibliography)

Other Professional Activities

Frequent speaker and lecturer at professional and trade association meetings and at seminars and symposia at various universities and colleges.

STRUCTURE AND GEOGRAPHY OF THE ELECTRIC UTILITY MARKET FOR COAL

by: Abraham Gerber

STRUCTURE AND GEOGRAPHY OF THE ELECTRIC UTILITY MARKET FOR COAL

A. Coal is often mistakenly thought of by the layman as a homogeneous fungible product. In fact, coal is a product with a wide range of diversity in its chemical and physical properties which must be thoroughly understood and carefully evaluated by those who buy and use coal.

Coals vary widely in their sulfur content, ash content, volatility, fusion temperature, grindability and Btu content, all of which are significant in determining whether a given coal is technically and/or economically usable in modern sophisticated electric utility boilers.

Although coal with any given set of physical and chemical characteristics can be burned in a boiler designed to do so, once a boiler is constructed, it is limited within a fairly narrow range to the use of the coal with those properties for which it has been designed. Apart from the physical limitation on the ability to burn coals that differ in their chemical and physical characteristics from the coal for which the boiler was originally designed, substantial departures from those characteristics can also have significant economic effects. For example, a lower BTU content could require the transportation of larger tonnages than was originally anticipated and a higher ash content could materially increase the cost of ash handling and/or boiler maintenance.

By far the largest market for coal both present and future in the states of the Midwest and nationally is the electric power generation market. This market also represents the only significant growth market for coal. It also exemplifies most clearly the factors that must be considered in arranging for coal supply.

B. Because of the need to assure a supply of coal that satisfies the physical and chemical requirements of the equipment designed, the complexities of administering multiple coal contracts and the development of large-scale transportation arrangements with their attendant economies, coal supply for large power plants is likely to be developed with few (two or three) producers. Indeed, many plants are supplied by only a single producer from a single mine opened specifically to serve that single facility.

In considering whether a particular coal mine can compete for the business of a power plant, several factors must be weighed. These include the cost of coal at the mine (this could vary widely for a number of reasons most important of which is the difference between deep and strip mining costs), the location of the mine relative to the consumer and the transportation costs involved, the Btu content of the coal and the suitability of the physical and chemical properties of the coal produced by a given mine for the power plant facility.

1. The Trend Toward Long-Term Contracts

In recent years, there has been a growing trend toward long-term contractual commitments to meet the coal requirements of a particular electric power generating plant. The increasing size of electric power generating units and plants has been accompanied by an increase in the quantity of coal required. A modern large coal-fired generating unit of a thousand Megawatts capacity may cost as much as 150 to 200 million dollars. This major investment can be jeopardized by a disruption in the supply of coal. Utilities are, therefore, concerned with assuring the supply of coal to such a plant over its life. A unit of this size would require approximately 2-1/2 million tons of coal annually or about 75 million tons of coal over its 30-year life. A plant containing three such units (a size likely to become increasingly commonplace) would, therefore require a total of committed minable reserves of well over 200 million tons. Furthermore prior to determining the type of fuel and the plant location, the utility makes every effort to arrive at a reasonably firm estimate of fuel costs for the life of the plant. Once the plant decision is made as to fuel and location, the utility will firm up the fuel cost estimates with long-term contractual commitments.

Prior to construction of the power plant, therefore, the utility will typically arrange long-term contracts for all or at least a major portion of the total fuel requirements of the plant. In doing so, it will not only seek the lowest possible price per Btu of delivered coal, it

will also seek assurance of the coal supplier's capability of providing the required quantities of coal over a long period of time. Utilities are, therefore, concerned about the reliability of the coal supplier and his past record of performance in satisfying contractual commitments. It will weigh heavily its previous experience with potential suppliers and will carefully investigate the availability of adequate reserves within the supplier's control to satisfy the contractual commitments. The utility will seek independent geological verification of the existence and size of the coal reserve and the physical and chemical properties of the coal. These are given careful review since the coal-burning equipment will be designed to handle the type of coal that is to be made available. The coal supply is arranged for prior to the construction of a plant and the location and design of a plant are frequently determined by the coal supply arrangements that can be made.

The long-term contractual commitments are not only desirable from the consumer's standpoint, but are also necessary from the viewpoint of the coal supplier. Such commitments generally require the development of new mining capacity. As a rule of thumb, a mine capable of producing a million tons of coal requires an investment of between six to ten million dollars. Coal producers have been reluctant to invest in new mining capacity in the absence of long-term contractual commitments for the major portion of the mine's capacity. Furthermore, obtaining

financial resources to develop new capacity often requires long-term contractual commitments.

In the electric utility market competition is not continuous in the sense that competitors may seek to serve this business on a daily, monthly or even annual basis. Rather, competition tends to be a one time thing. While competition may exist initially to supply the coal requirements of a particular electric generating plant, once the initial coal purchase is made, competition to satisfy the coal requirements of the plant is precluded for an extended period of time amounting to as much as 15 years or even the full 30-year life of the plant. Prior to the awarding of the coal supply contracts, several producers could be in competition to supply the coal requirements but once the coal contracts are awarded, competition is foreclosed.

2. Mine-Mouth Plants

When the electric generating plant is located in close proximity to the coal supply (such plants are often referred to as mine-mouth plants), assurance of the availability of an adequate coal reserve in the adjacent mining property to meet the lifetime requirements of the plant becomes even more critical. In the case of mine-mouth plants, it is often extremely difficult to arrange for an economically satisfactory alternative supply of coal should the original supplier be unable to meet the plant's requirements. In the case of a plant located so close to the mine, coal may be delivered directly from the mine to the power plant

on a conveyor belt, and the plant itself is likely to be built with no alternative coal receiving facilities. A new source of coal supply, therefore, would result in a substantial increase in cost.

3. Transportation

Where an electric generating plant is more remotely located from the source of coal, transportation costs impose limitations on competition. The cost of transportation is, in such cases a major component of the delivered cost of fuel so that differences in freight rates significantly affect the competitive position of any mine vis-a-vis a particular consuming facility. Furthermore, coal handling facilities at the consuming plant are often limited to serve only one form of transportation. For example, facilities may be provided for only barge delivery so that mines with no economic access to river transportation would be competitively foreclosed. Truck transportation is of little relevance in the case of the large modern generating units since it is only useful for relatively short distances and small tonnages. At the same time the more remote the plant from sources of coal the wider the choice among alternative suppliers under given cost conditions. Nevertheless, the availability of economic transportation and especially possibilities for single-line haul under volume or unit train arrangements, will have a major impact on the competitive alternatives. In such cases, the coal transportation costs may be affected more by rail movement patterns than by mere distance, and these differences in

transportation costs can readily outweigh the differences in mine prices. In other words, a mine may be foreclosed from competition by transportation elements beyond the coal producer's control.

While prior to the construction of electric power generating facilities, competition is broader than after plant construction and several potential suppliers may compete for the location of the power plant in an area that would make their own coal supply most advantageous, even this competition is limited by the needs of the electric power system and the power plant itself. The power plant requires large quantities of water for cooling purposes and a sufficiently large site not only for the plant itself, but also for coal storage and ash storage. In addition, the cost of transmission and system requirements with respect to voltage control and reliability must also be considered.

Thus, competition among mines for the location of a given power plant is limited by the combined effect of all these factors. Any determination of which mines can compete for the coal requirements of a particular facility must be based on the specific facts pertinent to that plant and the mines involved.

4. The Limited Spot Market for Coal

The trend toward long-term contractual commitments to meet the total requirements of a particular electric power generating plant has tended to eliminate, even though it has not eliminated altogether, the spot market for coal. From time to time, a utility consumer may

purchase small quantities of coal on the spot market and long-term contracts are often written to permit some flexibility for these and other purposes. However, because utilities are increasingly arranging for bulk transportation of coal supply on a long-term basis, the opportunities for spot purchases are declining except in those few cases in which small mines may be located in such proximity to make them capable of providing some relatively small deliveries at low cost.

The cost advantages of train-load deliveries compared with rail rates for car-load deliveries are such as to limit the desirability of such spot purchases. Furthermore, the growing practice of the coal producers of expanding mine capacity only to meet the long-term contractual commitments, and the gradual disappearance of the very small truck mines has tended to limit the production capacity available for spot sales.

C. Current production figures do not provide an adequate measure of a coal producer's market power. Because a major market for coal is the electric power generating market and long-term supply assurance is required, the critical determinant of whether a coal company is capable of offering effective competition as a coal supplier is the level of uncommitted coal reserves under its control. Current production reflects past commitments of coal reserves and these cannot be sold a second time. Additional sales for substantial quantities cannot be made without the existence of a verifiable uncommitted reserve within the coal producer's control.

In view of the factors noted above, as well as the respective reserve positions of United Electric and Freeman, the degree of potential competition that did or could have existed in the past between the two companies was within narrowly circumscribed limits. As to the future, United Electric's ability to compete with Freeman, or indeed, any other Midwestern coal producer, is severely impaired, if not totally vitiated, by its lack of uncommitted reserves.

The resources of United Electric Coal Company that are presently uncommitted to long-term contracts are smaller than the quantities necessary to satisfy the requirements of a major new electric generating unit. Unless continuity of supply can in some way be assured by the reserves available to Freeman Coal, the small uncommitted reserves of United Electric Coal Company would not be considered as a significant source of supply for a large electric generating unit.

AVERAGE SIZE OF STEAM-ELECTRIC GENERATING PLANTS AND NEW UNITS 1/ UNITED STATES 1938, 1947 AND 1951-1966

Year	Average Size	
	New Units	Plants in Use
	--------(Megawatts)--------	
	(1)	(2)
1938	33	102
1947	39	118
1951	60	131
1952	66	139
1953	68	144

1964	220	311
1965	283	331
1966 2/	325	355

1/ As selected by the Federal Power Commission for inclusion in the annual statistical summaries (which did not include Rural Electric Cooperatives prior to 1966). In 1965, the number of plants (501) included in the summary accounted for 88 per cent of the contiguous U.S. electric utility industry's installed conventional steam-electric generating capacity of 188,213 Megawatts and for 93 per cent of the total net generation; figures for 1966 cannot be similarly compared because the effect of inclusion of the Cooperatives cannot be accurately measured in previous years.

2/ Excluding Rural Electric Cooperatives reported for the first time in 1966, when they accounted for 25 plants of 83-Megawatt average size and ten new units of 106-Megawatt average size.

ABRAHAM GERBER

Abraham Gerber was born in New York in 1925. He received his bachelor of arts degree from Columbia College in 1948 and a master's degree from Columbia University in 1950, after which he attended the New School for Social Research for a year on a graduate scholarship.

In 1951 Mr. Gerber joined the Department of Commerce Office of Business Economics in the Input-Output Section. Shortly thereafter he joined the Bureau of Mines of the Department of the Interior, where he headed the Energy Section in the Input-Output Group of the Office of the Chief Economist.

In 1953 Mr. Gerber joined the American Electric Power Service Corporation and was appointed Administrative Assistant to the President of American Electric Power Company.

In 1961 he was appointed Secretary of the newly established System Development Committee, a committee of the Board of Directors charged with the responsibility for exploring new areas in the technical and economic development of the AEP System in all phases of its activities including such technical developments as magnetohydrodynamics research programs, nuclear power, extra-high-voltage transmission, fuel resource development, and electric transportation. He continued to do research in fuel and energy with particular emphasis on the economics

of nuclear power and the competitive relationship between nuclear power and fossil fuels as sources of electric energy generation. He also continued to provide economic projections and load forecasts for planning electric power facilities on the American Electric Power System and to provide the President of American Electric Power Company with data and analytical material on economic matters.

Mr. Gerber served as consultant to President Eisenhower's Cabinet Committee on Energy in 1953, as Secretary of the Subcommittee on Energy and Raw Materials Resources of the Engineers Joint Council Engineering Research Committee in 1961-1962, as a member of the Technical Advisory Committee of the Office of Coal Research from 1961 to the present, as a member of the Fuels Special Technical Advisory Committee of the Federal Power Commission National Power Survey in 1962-1964, and has worked closely with the Appalachian Regional Commission. He authored a technical paper and served as a reviewer of technical papers for the recent Interdepartmental Energy Study of the Federal Government.

Mr. Gerber has written numerous articles and research papers including: "The Outlook for Uranium," with John Hogerton and Leonard Geller; "The Impact of Air Pollution Control on the Economics of Energy Supply," presented at the American Power Conference in April 1965; and "Soviets Find Capital Costs Make Hydro Less Economical," with Philip Sporn for Electrical World. He recently co-authored a paper

entitled "The Social-Economic Evaluation of Water Resource Projects," presented before the International Conference on Water for Peace last May.

Mr. Gerber also has lectured before a graduate seminar on nuclear power at Massachusetts Institute of Technology.

COAL RESERVES AND DEEP MINING
REPORT BY PAUL WEIR COMPANY
GENERAL DYNAMICS, ET AL.
vs.
UNITED STATES

Analysis of Strip-Mining Potential of Specific Coal Fields

Based on engineering data made available to us by United Electric Coal Companies, a subsidiary of General Dynamics, and on our own specialized and general knowledge of coal characteristics on the Midwestern coal fields, we have made the studies deemed necessary by us to analyze the strip-mining potential of the following coal fields, as specified by the Government in their answer to Interrogatory 44 (although not in the same order):

1. Industry Field.

2. South of the Industry Field, toward the town of Rushville, Illinois.

3. Augusta Field, located approximately ten miles west of the Industry Field.

4. Meredosia-Mount Sterling area, located in Brown County, Illinois.

5. Spring Lake Township area, Tazewell County, located directly south of the Banner Mine across the Illinois River.

6. Salt Fork Field, located near Catlin, Illinois.

7. Fidelity Mine deep coal.

Industry Field

Coal Bed Location and Occurrence

The Industry Field is located largely in the southeastern portion of Township 4 North, Range 3 West (McDonough County), with short extensions into Township 4 North, Range 2 West (McDonough County) and Township 3 North, Range 3 West (Schuyler County). At these locations the Illinois No. 2 coal bed underlies portions of a comparatively flat upland known as Gin Ridge, outcropping on both sides of Grindstone Creek, on the northern side of the ridge, and on both sides of Willow Creek, on the southern side of the ridge. The actual coal outcrop is seldom exposed, but numerous local mines have been operated near the approximate lines of outcrop, with their individual areas of depletion being unknown. A number of drill holes put down by United Electric in their exploratory program encountered "old works".

Where not partially eroded or missing, the No. 2 bed generally ranges from 24 to 30 inches in thickness. It seldom occurs in its normal thickness under less than 25 feet of cover, usually being thinned or too soft to mine where the overburden is less than 25 feet in thickness. The coal bed undulates to some extent, being either higher or lower than its expected level of occurrence within fairly broad areas of irregular shape. It has been either eroded or was never deposited in a narrow, channel-shaped strip across the center of the property, although the horizon where the coal bed should occur is well below a cover thickness of 25 feet.

Estimated Reserves

There are approximately 3,686 coal acres within the surface properties controlled by United Electric, and approximately 1,587 additional coal acres in adjoining lands not controlled by the Company, but presumably obtainable should mining operations be contemplated. With a weighted average thickness of 28.26 inches within the United Electric properties and of 27.68 inches within the adjoining properties, the total reserves of raw coal in place before mining would be 15,625,000 tons and 6,589,200 tons, respectively. At an assumed overall recovery of 68 percent after mining and conventional cleaning, the recoverable merchantable reserves would be 10,625,000 tons from the properties controlled by United Electric, and 4,480,700 tons from the adjacent properties, a total of 15,105,700 tons.

Overburden Characteristics

The soft, unconsolidated surface material underlying Gin Ridge and the slopes of Grindstone and Willow Creeks usually ranges from 15 to 25 feet in thickness. The interval from the base of this soft material down to the coal bed commonly consists of a hard gray shale, frequently sandy, and occasionally containing a bed of hard sandstone. This sedimentary, consolidated material would have to be broken by blasting before removal by stripping equipment.

Overburden Ratios

With a weighted average thickness of overburden of 53.44 feet within the United Electric properties and of 58.83 feet within the adjoining properties, the ratios of cubic yards of overburden to ton of merchantable coal would be 29.91 and 33.62, respectively.

Quality

The available analyses of the coal bed within the United Electric properties indicate that Coal No. 2 in the Industry Field is approximately similar in quality to the No. 2 coal elsewhere in this area except that it is notably higher in sulfur content.

Conclusions

The Industry Field has been well drilled, so that the available information concerning its stripping characteristics and other attributes is specific and comprehensive. With reserves of somewhat irregular coal continuity and occurrence, and with high overburden ratios, together with no better than average quality, at best, we consider the strip-mining potential of this area as distinctly marginal. These reserves, in our opinion, would not be competitive in the foreseeable future with reserves now being mined or held for future operation elsewhere in Illinois, Indiana and West Kentucky.

South of the Industry Field, Toward the Town of Rushville, Illinois

Coal Bed Location and Occurrence

The specific areas of interest that pertain to the above heading of a coal field "South of the Industry Field Toward the Town of Rushville, Illinois", consist of two isolated tracts in Schuyler County in which United Electric obtained a few land properties which were drilled for exploratory purposes and then relinquished. One such tract is situated in Sections 15 and 14, Township 3 North, Range 3 West, one mile south of the southern margin of the Industry Field proper. The second such tract is contained within Sections 4, 8 and 9, Township 2 North, Range 2 West, approximately seven miles southeast of the first tract and five miles northwest of the town of Rushville.

There were 15 drill holes put down in and near the properties in Sections 15 and 14. Only two of these holes encountered the Illinois No. 2 coal bed at its proper horizon and normal thickness. The other drill holes were negative, and were either started below the horizon of the No. 2 coal or encountered No. 2 coal in less than full thickness.

There were 14 drill holes put down within and near the properties in Sections 4, 8 and 9, all of which were negative with the maximum coal thickness in any such holes being 19 inches. Most of these holes were sufficiently deep to indicate that the No. 2 coal horizon was definitely missing.

Conclusions

The region extending south and southeast of the Industry Field toward Rushville, Illinois, as indicated by the exploration work done by United Electric, is obviously unsuitable for further consideration for mining.

Augusta Field, Located Approximately Ten Miles West of the Industry Field

Coal Bed Location and Occurrence

The Augusta Field is located in Hancock and Schuyler Counties immediately south of the town of Augusta, approximately ten miles southwest of the Industry Field. While this field lacks specific delineation it occupies southern portions of Ranges 6 West, 5 West and 4 West, all in Township 3 North, and major portions of Ranges 6 West, 5 West and 4 West, all in Township 2 North. Within this area the Illinois No. 2 coal bed intermittently underlies a broad upland area between westward-flowing headwaters of drainage systems flowing ultimately into the Mississippi River near Quincy and southeastward-flowing streams draining into the Illinois River. The eastern portion of the upland area is irregularly dissected by Williams and Cedar Creeks. While there has been local stripping in stream bottoms just south of the Augusta area, the actual coal outcrop is seldom exposed. Indications of local mine operations along the outcrop lines are relatively infrequent, suggesting difficulties in access or operation.

While ranging where present from 24 to as much as 34 inches in thickness, the general average thickness appears to be about 28 inches. The information available from drilling suggests that the coal bed is not uniformly present along the horizon where it should be encountered. It abruptly disappears under level uplands for irregular distances. It sometimes occurs on one side of a tributary stream but not on the other.

The No. 2 coal bed is occasionally underlain at a vertical interval of about 20 feet by a very irregular lower bed which appears to range from 14 to 24 inches in thickness. Analyses of this lower bed indicate abnormally high contents of ash and sulfur and this bed is not considered as any portion of the potentially strippable Augusta Field.

Estimated Reserves

Although the overall area is large, the amount of drilling is too insufficient, and the presence of areas of missing coal too strongly suggested, to permit any estimates of reserves. The apparent outcrop of the bed across the broad western portions of the field is very deep, with a cover thickness of approximately 50 feet where stripping would have to begin. In such areas the thickness of overburden increases rapidly to 75 and 100 feet.

Overburden Characteristics

The soft, unconsolidated material at the surface of the Augusta area is generally quite thin, ranging up to 20 feet in thickness but

generally averaging about 10 feet. The sedimentary strata between the base of this soft material down to the coal bed generally consist of a hard sandy shale, frequently containing one or more beds of hard sandstone ranging up to 15 feet in thickness. The stratified portion of the overburden above the coal would require relatively heavy blasting before removal by stripping equipment.

Overburden Ratios

While specific overburden ratios within the Augusta Field as a whole cannot be determined because of the lack of information on coalbed occurrence within the field, it is probable that it would be prevailingly high.

Quality

The available analyses of the coal bed within the Augusta Field indicate that the coal is generally similar in quality to that of No. 2 coal elsewhere in this area.

Conclusions

The Augusta Field has been but sparsely drilled, so that there is not sufficient information for determining its operating characteristics. With difficult overburden characteristics and high overburden ratios, together with no better than average quality, we consider the strip-mining potential of this area as inferior. The reserves, in our

opinion, would not be competitive in the foreseeable future with reserves now being mined or held for future operation elsewhere in Illinois, Indiana and West Kentucky.

Meredosia-Mount Sterling Area,
Located in Brown County, Illinois

The combination of place names in the above title is misleading in that the Mount Sterling (Ripley) area in Brown County is on the west side of the Illinois River while the Meredosia area is separately located a substantial distance south of Mount Sterling on the eastern side of the Illinois River in Morgan and Scott Counties.

Ripley-Mount Sterling Area,
Located in Brown County, Illinois

Coal Bed Location and Occurrence

The Ripley Field (Ripley being approximately six miles northeast of Mount Sterling) consists of scattered properties in the southern portion of Township 1 North, Range 2 West, north of Crooked Creek, and of a relatively small, compact area south of Crooked Creek in the southwestern corner of the same township. Both of these two separate areas are dissected by tributary channels flowing into Crooked Creek. There has been but little local mining in this field.

Where present, the No. 2 coal bed hovers around 24 inches in thickness. This coal is either quite erratic in occurrence or too deep to be considered as strippable in the properties north of Crooked Creek. While apparently uniform in occurrence south of the Creek the available area is small, with the coal bed not only being thin but going rapidly under deep cover south and west of the prospective area.

Estimated Reserves

The area north of Crooked Creek is too erratic in coal occurrence to permit any estimate of reserves. The small area south of the Creek contains approximately 2 million tons of recoverable coal but would have a high overburden ratio because of its relative thinness.

Overburden Characteristics

The soft surface material in the area south of Crooked Creek is generally thin so that the normal interval of sandy shale down to the top of the coal bed would have to be blasted prior to stripping.

Quality

The analysis of one drill core indicates that the No. 2 coal at Ripley is approximately similar in quality to No. 2 coal elsewhere in this field.

Conclusions

The area adjacent to the town of Ripley south of Crooked Creek has been well drilled, but with the thinness of the coal and high overburden ratio, and with its limited extent, we consider the strip-mining potential of this area as inferior. The reserves, in our opinion, would not be competitive in the foreseeable future with reserves now being mined or held for future operations elsewhere in Illinois, Indiana and West Kentucky.

Meredosia Area,
in Morgan and Scott Counties, Illinois

Coal Bed Location and Occurrence

The Meredosia field was explored over a considerable geographic area by conducting drilling operations in small, scattered properties located in Range 12 West, Township 16 North, Ranges 13 and 12 West, Township 15 North, and Ranges 13 and 12 West, Township 14 North. This overall area is approximately 16 miles north-south, and seven miles east-west in extent. The town of Meredosia is on the Illinois River, about five miles west of the northern portion of the explored area. The coal-bearing area occupies the upland facing the broad Illinois River valley which is heavily dissected by westward-flowing creeks and tributaries. Local mining operations are few and scattered, being located mainly in the deeper drainage valleys near small towns.

While probably present throughout the area, the No. 2 coal is prevailingly deep, ranging from 50 to 100 feet or more over broad areas. The coal bed ranges from 24 to 31 inches in normal thickness. The overburden generally consists of up to 75 feet of soil and glacial deposits, and the sedimentary strata between the bottom of the glacial deposits and the top of the coal bed commonly contain varying thicknesses of sandstone.

Conclusions

While the work done by United Electric in the Meredosia area was primarily of an exploratory nature, the results are sufficient to indicate that the area is not potentially strippable because of the prevailingly excessive depth of overburden.

Spring Lake Township Area, Tazewell County

Coal Bed Location and Occurrence

The portion of Spring Lake Township (Ranges 7 and 6 West, Township 24 North) designated as the Spring Lake Township Area is located in the essentially flat bottom lands comprising the Illinois River valley south of the channel of the Illinois River. The coal bed does not outcrop nor has it been mined in the vicinity of this area. It is being mined, however, north of the river in Townships 6 and 7 North, Ranges 5 and 6 East, by the United Electric Coal Companies at their Banner Mine.

The No. 2 coal bed south of the river in Spring Lake Township appears to be very limited in areal extent. The thickness of coal encountered in six drill holes ranged from 17 to 29 inches, with an average of 22 inches. Where it was found to be present, the bed underlies a veneer of water-bearing valley sediments approximately 20 feet in thickness, below which there is a hard gray shale, sometimes sandy, to the top of the coal bed. Elsewhere within the area explored, drilling encountered up to 48 feet of unconsolidated strata, suggesting that the coal bed does not uniformly underlie the valley floor but was either eroded or never deposited in irregular areas.

The amount of drilling is too insufficient, and the presence of areas of missing coal too strongly suggested, to permit any estimates of reserves.

Quality

The available analyses indicate that this coal is approximately similar in quality to No. 2 coal elsewhere in this field except that it is notably higher in sulfur content.

Conclusions

The Spring Lake Township area is too limited in extent, without any indications of potential expansion in total area, to suggest any possibilities of commercial operation.

Salt Fork Field,
Located Near Catlin, Illinois

Coal Bed Location and Occurrence

The Catlin Field is located largely in the south-central portion of Township 19 North, Range 12 West (Vermilion County), just northwest of the town of Catlin, which is approximately six miles southwest of the city of Danville, Illinois. At this location the Illinois No. 7 coal bed underlies a comparatively flat upland just south of Salt Fork at its confluence with the Vermilion River. Some of the earliest commercial strip mining in Illinois took place in the flat bottom lands of Salt Fork and Vermilion River. There is an active stripping operation on the north side of the Vermilion River approximately three miles west of Danville.

During and shortly after its exploration of the Catlin Field, United Electric also prospected the valley of Vermilion River approximately two miles north of the then northernmost limit of the old stripped-out area. A few drill holes were also put down in upland terrain approximately four miles west of Catlin.

The No. 7 coal bed under these three scattered areas ranges from 68 to 76 inches in thickness, with a general average of 6'0". It is persistent within the explored areas but lies under relatively high cover in all of the three areas thus tested.

Estimated Reserves

The drilling programs were too limited in extent to determine specific estimates of reserves, although the Catlin area is obviously large. The original United Electric Catlin Field, in fact, plus extensive areas east and west of this field, are now in the hands of another company, representing inactive reserves.

Overburden Characteristics and Ratios

The overburden strata, both in the river bottoms to the north, and in the upland areas south of Vermilion River, generally consist of relatively thin surface material underlain by shales, sandy shales and sandstones. Such overburden would have to be blasted before removal by stripping equipment. The thickness of overburden in the areas drilled was generally over 80 feet, ranging up to 110 feet in the Vermilion River flats, up to 120 feet in the Catlin area proper, and up to 165 feet in the area four miles west of Catlin. Overburden ratios would approximate 25:1 or more.

Quality

The No. 7 coal in the general Danville Area is slightly higher in ash and slightly lower in sulfur as compared with most other Illinois coals.

Conclusions

The Catlin Field is no longer available, but with its high overburden ratios, would be considered as distinctly marginal when compared with most coal reserves now being mined or held for future operations elsewhere in Illinois, Indiana and West Kentucky.

Fidelity Mine Deep Coal

Coal Bed Location and Occurrence

The Fidelity "Deep" area is located in the southeastern part of Section 27 and the eastern part of Section 28, Township 6 South, Range 2 West (Perry County), and in the northwestern corner of Section 2 and the northeastern corner of Section 3, Township 7 South, Range 2 West (Jackson County). Lying between what will eventually become the final limit of stripping of the Fidelity Mine at the approximate 85-foot cover line as its western boundary and the large Kathleen underground mine as its eastern boundary, the area is approximately 1.75 miles north-south and 0.625 miles east-west in extent.

The Illinois No. 6 coal in the Fidelity "Deep" area is persistent ranging from 66 to 110 inches in thickness.

Estimated Reserves

There are approximately 794 coal acres within the Fidelity "Deep" tract. With a weighted average thickness of 83.67 inches, the reserves of raw coal in place before mining would be 9,965,000 tons. At an

assumed overall recovery of 72 percent after mining and conventional cleaning, the recoverable merchantable reserves would be 7,175,000 tons.

Overburden Characteristics

The overburden commonly consists of up to 58 feet of unconsolidated surface and glacial material, below which the sedimentary strata consist of shales, sandy shales and occasionally sandstone. A persistent massive limestone bed, ranging from one to 14 feet in thickness and lying from 3 feet to 25 feet above the coal bed, is also included in the overburden. Such strata are difficult to handle and would require selective and heavy blasting before removal by stripping equipment.

Overburden Ratios

With a weighted average overburden thickness of 89.48 feet, the ratio of cubic yards of overburden to ton of merchantable coal would be 15.98:1.

Quality

While not specifically tested, the quality of the No. 6 coal in this area is considered to be essentially the same as that of the No. 6 coal being mined at the Fidelity Mine.

Conclusions

The Fidelity "Deep" field has been well drilled, so that the available information concerning its stripping characteristics is specific and comprehensive. With its difficult overburden characteristics and high overburden ratio, we consider that there is virtually no strip-mining potential for this area. It would be impossible to strip mine these coal reserves at a cost comparable to the coal production costs of the other stripping operations and reserves yet to be mined in the Belleville District.

Economics and Reserve Position
Bituminous Coal Mining
Illinois, Indiana and West Kentucky

For some time, strip mining has been providing an increasing share of coal output in the Tri-State Area. Table 1 shows annual production for the years 1949 through 1967 for strip mines, underground mines and all mines. The proportion mined by stripping has increased from 39.90 percent in 1949 to 64.94 percent in 1967. Production from underground mines declined from 60,461,000 tons in 1950 to 38,596,000 tons in 1961. Since that time, underground production has gradually increased to a level of 45,666,000 tons in 1967.

Bulletin 1252-C of the U. S. Geological Survey entitled "Stripping-Coal Resources of the United States" (1968), contained this summary of recent work by the Illinois Geological Survey:

". . . in 1955 the Illinois Geological Survey began a new program of study of stripping coal that has yielded five reports to date (Smith, 1957, 1958, 1961; Smith and Berggren, 1963; Reinertsen, 1964). On the basis of work completed and in progress, J. A. Simon (written commun., Sept. 28, 1966) has concluded that the remaining stripping-coal resources of Illinois as of January 1, 1966, in beds 18 inches or more thick and at a maximum depth of 150 feet, total 21,223 million tons. Simon also concluded that the original resources within the same parameters totaled about 23,000 million tons."

With a record of past growth and what might seem to be an assured resource base on which to build, it would appear that strip mining would continue its record of growth. Actually, estimates of strippable coal reserves of Illinois are misleading. Strippable coal as defined by the Illinois Geological Survey includes coal seams that are 18 inches or more thick with an overburden not more than 150-feet thick. A substantial proportion of the strippable reserves as thus defined are not economically recoverable as of the present time and may never be economically recoverable. In a paper entitled "An Evaluation of Illinois Coal Reserves Estimates," presented at the 76th Annual Meeting of the Illinois Mining Institute in Springfield, Illinois, October 25, 1968, by J. A. Simon and W. H. Smith of the Illinois Geological Survey, these comments were made:

> "Use of the words minable and strippable as applied to Illinois reserve studies, although defined in the studies, has been too often literally interpreted . . .. Some misuse of these data has been made."

The concluding remarks of the paper include this statement:

> "Although total remaining coal reserves of Illinois are considered to be conservative as defined (emphasis added) in studies to date, minable or strippable reserves based on these data will be much smaller (emphasis added) if defined by greater minimum thickness or modified by definitions of economic minability."

In a paper entitled "Coal Strip Mining - Is It Reaching A Peak?", by Hubert E. Risser, Assistant Chief and Principal Mineral Economist, Illinois Geological Survey, presented at the Fall Meeting of the Society of Mining Engineers in Minneapolis, Minnesota, September 18, 1968, the following summary was presented:

"For half a century the percentage of coal production provided through strip mining has steadily increased. Recent trends indicate that a peak in percentage, if not in tonnage, is being approached. Important among the reasons for this is the decline in economic advantage enjoyed by strip mining compared to underground mining. Among the factors contributing to this decline are the following:

"1. Decrease in the margin of advantage in manpower requirements held by strip mining.

"2. Increase in depth and volume of overburden necessitating larger equipment and investment of more capital.

"3. Increasing scarcity of reserve blocks of land big enough to support extensive mining operations.

"4. Increasingly stringent legislation for reclamation of stripped land and the resulting higher cost of reclamation.

"5. Increasing cost of land surface rights.

"In the eastern part of the United States there has already been a peaking and decline in the relative importance of strip mining in some major coal producing states. Although it is not clear at what point the pressures discussed above will cause a peaking for the region as a whole, the trends indicate that this definitely is on the way."

In order to give a perspective on trends in the Tri-State Area Tables 2, 3 and 4 present information on new coal mines which were placed in operation or announced during the period from 1959 to date. As shown in Table 2, which presents data on deep coal mines, the Orient No. 5 Mine of Freeman Coal Mining Corporation and Mine No. 21 of Old Ben Coal Corporation were placed in operation in 1959. After 1959, no new deep mines were developed until 1964. Since that time, 18 deep mines have been placed in operation or announced. As shown in Table 4, the total number of mines announced or placed in operation for the period was 20 mines having an approximate annual capacity of 44.5 million tons.

Table 3 presents similar information on strip coal mines. Since 1959, 16 new mines having an approximate annual capacity of 34.3 million tons have been placed in operation or announced. The most recent mine to be announced was the Leahy Mine of Ayrshire Collieries Corporation. This mine is in Perry County, Illinois, and will strip the reserves in the Denmark Field. These reserves are known in the industry as the last undeveloped major reserve of strippable coal in the Tri-

State Area and we doubt that any new comparable strip operations can be developed in the Tri-State Area.

We specifically point out the strip mines listed on Table 3 are based on coal reserves which had been in the hands of the operating company or precedessor companies for many years before development commenced. For example, the Denmark lands, on which the Ayrshire Collieries Corporation Leahy Mine will be developed, were assembled into a block in about 1927 by a predecessor company.

The summary shown on Table 4 does indicate the way in which underground coal production is increasingly supporting the growth in production in the Midwest. This trend must continue. In addition to the deep mines listed, we know of several underground operations which will definitely be developed but have not been announced. In contrast we know of no major strip mine which will be developed but has not been announced.

Counsel for defendants in United States v. General Dynamics, et al. have provided us with the following schedule of midwestern coal reserves controlled by producing companies (and excluding reserves controlled by Standard Oil Company (New Jersey) or affiliates):

Midwestern Coal Reserves Controlled by Producers
(Million Tons)

	Dedicated to Existing Mines	Other Reserves	Total
Strip	1,148	646	1,794
Deep	1,133	6,412	7,545
	2,281	7,058	9,339

In comparing these resource bases with the production of strip and deep coal in the Tri-State Area (84.6 million tons strip and 45.7 million tons deep, according to the most recent U. S. Bureau of Mines statistics), the index of remaining life for strip coal would be 21 years and for deep coal 165 years. Actually, of course, the production of any natural resource does not continue at a level rate and then cease. Over a period of time the plot of production will assume a bell-shaped curve with production increasing, gradually reaching a peak, and then declining. It is evident that reserves of strippable coal are limited in relation to the present level of production. For this reason we believe that peak production of strip coal will be reached within a very short time and a gradual decline will ensue thereafter. Meanwhile, there will be substantial growth in underground production. In 1980, we project that 75 percent of production in the Tri-State Area will come from deep mines.

An obvious question is whether additional strippable coal reserves can be found in the Tri-State Area to add to the relatively limited strip reserves shown in the above table.

The most important factor in determining whether coal reserves are economically recoverable by stripping is the overburden ratio; that is the cubic yards of overburden which must be removed to uncover a ton

of coal. Obviously, the reserves lying under shallower cover are the most attractive and are mined first. Overburden ratios for remaining reserves are increasing.

Tables 5a, 5b and 5c are presented to show the effect of overburden ratios and other factors affecting the economics of strip mining in the Midwest. The annual production assumed is 2,000,000 tons and four hypothetical mines are presented having overburden ratios of 12.6, 14.7, 19.6 and 25.2 cubic yards per ton. The life of each mine is assumed to be 20 years. It is assumed that for all four mines stripping equipment capable of digging to a maximum height of 100 feet is employed. The greater overburden ratio is assumed to be due to lesser coal thickness. As shown, the coal acres required vary from 5,128 acres for the 12.6 ratio to 10,417 acres for the 25.2 ratio. These are substantial areas in any case, and acquisition of blocks of such size is extremely difficult if not impossible. Even if lands of such size were available, land costs are steadily rising. For our studies we have assumed an average cost of $500 per acre. In many areas costs are as much as $800 to $1,000 per acre.

We assume that a single stripping shovel would uncover all of the overburden. The capacity of the stripping shovel varies from 90-cubic yards for the 12.6 ratio to 180-cubic yards for the 25.2 ratio. This is the largest stripping shovel which has yet been built. As can be seen from Table 5a, the cost of the stripping shovel is the major element of capital cost for a strip mine. The total initial investment for all plant and equipment and coal lands for the strip mines increases

from $6.39 per annual ton for the 12.6 ratio to $11.75 per annual ton for the 25.2 ratio.

Table 5b shows the estimated costs of production for the four hypothetical mines. The direct operating cost per yard of material moved is estimated to be 5.5 cents per cubic yard for the 90-cubic yard shovel and 5.0 cents per cubic yard for the 105-cubic yard shovel. The cost per yard for the 140- and 180-cubic yard shovels is assumed to also be 5.0 cents per cubic yard. The increased size of the shovels does not result in reduced costs per yard.

The total cost of production including depreciation and depletion increases from $2.836 for the 12.6 ratio to $4.128 for the 25.2 ratio. In order to place these costs in further perspective, we have calculated the sales realization which would be required to make the hypothetical mines attractive coal mine investments. We have assumed a rate of return of 12 percent on investment. The realization necessary on this basis varies from $3.635 for a 12.6 ratio to $5.721 for a 25.2 ratio. The detail on these calculations is shown on Table 5c. In 1967 the average values per ton for mines in Illinois, Indiana and West Kentucky were $3.88, $3.99 and $3.42, respectively.1/ From these data it can be seen that the prevailing level of sales realizations would not permit economically viable mining of coal at high overburden ratios. Under average conditions we would estimate a maximum economic ratio in the Tri-State Area as of the present time of about 18-cubic yards per ton.

1/ U. S. Bureau of Mines Minerals Yearbook, 1967.

There are, of course, instances where coal under somewhat heavier ratio can be mined economically because of overburden which does not require shooting and/or because of high sales realization due to favorable transportation arrangements.

The relationship shown between overburden ratio and sales realization necessary for an adequate return on investment is essentially linear. For each one point increase in ratio an additional 16.5 cents per ton in realization is necessary for an adequate return.

The investment required for underground mining is substantially less than for strip mining under heavy overburden. As of the present time, the investment per annual ton for an underground mine in the Tri-State Area approximates $5.00 to $6.00. This compares with investments per annual ton for the hypothetical strip mines of from $6.39 to $11.75. As overburden ratios increase, a point is reached where underground mining is cheaper than strip mining.

Commercial coal producers in Illinois, Indiana and West Kentucky have been faced for some time with a deteriorating strip reserve position. Reserves held by operating companies are inadequate to support a sufficient number of new mines which could produce at competitive costs. Such existing unassigned reserves are generally characterized by higher overburden ratios and smaller blocks of land often insufficient to support economic operations. Despite diligent search, operators have been unable to find economically strippable reserves not now controlled

by others.2/ It is clear that operators will not be able to replace strip mines being worked out, let alone attempt to supply any growth in coal demand. For the industry as a whole, and for specific companies, underground coal production must not only supply the growth in coal demand, but also replace strip production as strip mines are depleted.

Ability of United Electric to Undertake Successful Deep Coal Mining

The primary deterrent to initiating deep mining for any coal or non-coal company not already having a deep-mining organization is the crucial and critical shortage of miners, supervisors and technically-trained people. During the period subsequent to World War II, the coal industry suffered from declining markets and production. Not until 1960 did the growth in the primary market, electric utilities, offset loss of other markets. The image of the industry in the 1950's was sick. Mining schools were closed because of lack of students. Ohio State, Pittsburgh, Lehigh and the University of Illinois all closed their mining departments. It is almost inconceivable that Illinois, with the largest reserves of bituminous coal in the nation, does not offer a degree in mining engineering at the University. Because of the decline in the 1950's, few miners entered the industry. Presently, there are too many employees in the upper age brackets, ex-experienced but old, and too many in the lower age brackets, young and

2/ See our letter of July 12, 1967, attached hereto, the accuracy of which we reconfirm.

inexperienced. There are too few in between. Presently, many companies are resorting to training schools to get miners and supervisors.

Coal mining by deep methods is very specialized in comparison to surface mining. Surface mining is in many ways analagous to earth moving. Deep mining requires more expertise and expertise quite different and distinct from that required for strip mining. Deep mining also involves more risk. Generally, coal companies have relied on either strip mining or deep mining, not both. The exceptions to this have been companies of one primary type of mining which acquired or were merged with companies of the other primary type. For example, Consolidation Coal Company became both a strip-mining and deep-mining company through the merger of Pittsburgh Coal Company (deep), Christopher Coal Company (deep), Hanna Coal Company (deep and strip), Pocahontas Fuel Company (deep) and Truax-Traer Coal Company (strip). Peabody Coal Company became both strip and deep when the Sinclair Coal Company (strip) was merged into Peabody (deep). There has been a great reluctance on the part of the management of strip-mining companies to try deep mining.

In order to undertake deep mining United Electric would have had to acquire a deep-mining organization in spite of extreme shortage of competent personnel. Management would have had to accept responsibility not only for economically viable deep-mining projects, but for the safety of personnel. This latter requirement has particularly troubled managements oriented toward strip mining alone. While it is, of course,

impossible to state for certain whether or not United Electric would even have attempted to undertake deep mining, it is improbable that they could have done so successfully, and, therefore, highly unlikely that they would have tried. This would have been true even if United Electric had had the best deep-mining reserves to work with. We believe that the integration of control of United Electric and Freeman was a logical and desirable step for United Electric as a company with very limited strippable reserves and no deep-mining team.

Respectfully submitted,

PAUL WEIR COMPANY

Mr. Frank Nugent, President
Freeman Coal Mining Corporation
307 North Michigan Avenue
Chicago, Illinois 60601

Dear Mr. Nugent:

For the past forty-seven years I have been a resident of Illinois and have been in the coal industry continuously during these years. For the first sixteen years I was engaged in engineering and production for a major Illinois coal operator. For the past thirty-one years I have had my own firm of independent mining engineers serving as consultants to entities interested in coal reserves and mining.

In the tri-state area of Illinois, Indiana and West Kentucky my firm has rendered services to all of the major coal producers, to the United States Army Corps of Engineers, to the major utilities operating in this area, to the railroads, to financial institutions, to major oil companies and others. In this work we have had the opportunity to study and become familiar with the coal reserves in the hands of our clients as well as the estimates of the Illinois State Geological Survey.

For the purposes of demonstrating the ultimate availability of strippable coal reserves, you have asked our opinion as to the availability of areas in the State of Illinois of strippable coal reserves containing as much as 10 to 20 millions of recoverable tons and not now owned or under option to coal operators, with emphasis on the Fulton-Peoria-Stark-Knox Counties fields. The only reserves in Illinois that can be considered for strip mining are found in Seams No. 5, No. 2 and No. 6, and our discussion is limited to those seams.

In the Fulton-Peoria area, the No. 5 Seam has been the one most widely mined. Remaining strippable reserves of any consequence in this seam are owned and/or controlled by two operating companies, United Electric and a competitor.

Some production has come from the No. 6 Seam, principally in the northern part of the county (Fulton). The strippable coal reserves extend north into Knox County. Mining in the No. 6 Seam is substantially different from that in the No. 5 Seam. The seam (No. 6) is thinner, the quality of the coal as mined is substantially inferior, and there is a lack of uniformity of coal occurrence. The stripping ratio (cubic yards of overburden to one ton of marchantable coal) is much greater than in the case of No. 5 Seam.

Presently there are two strip mines working in the No. 2 Seam in Fulton County. One was developed in 1958 and the other in 1962. The one mine is located on the Illinois River and utilizes barge transport exclusively. The other is located sufficiently close to the River to take advantage of barge transport. This lower cost transportation tends to offset the higher production cost of the No. 2 Seam coal. The thickness of the No. 2 Seam is approximately one-half that of the No. 5 Seam.

The Illinois Geological Survey has made estimates of the quantities of coal that occur at various depths below the surface. These estimates have no relationship to the profitability or lack of profitability of strip mining. Likewise, the estimates do not reflect the availability of surface. There are large areas that lie within the corporate limits of towns and cities. Accordingly, those estimates do not demonstrate and were not intended to demonstrate the availability of strippable reserves that can be mined profitably.

The ceiling on the price obtainable for coal for steam raising purposes is now being established by nuclear fuel. In addition, there has been tremendous progress in recent years in the development of larger and larger excavating equipment for removing the overburden from the coal seam. The effect of this has been to permit the removal of as much as 125 feet of overburden thickness from the former limit of 55 to 60 feet. A special problem arises when the overburden thickness exceeds 125 feet. This problem concerns the stability of the spoil bank which renders improbable any future technological progress in this regard. The effect of these two factors is to limit the amount of stripping of the No. 2 and No. 6 Seams that can be profitably accomplished and, in our opinion, reserves in these seams of any consequence that can be mined profitably are already controlled by operating companies.

PAUL WEIR COMPANY

Mr. Frank Nugent

July 12, 1967
- 3 -

The status of available strip coal reserves in other parts of the State of Illinois is similar to that in the four-county field. This is particularly the case in the so-called Belleville area (Jackson, Perry, Randolph and St.Clair Counties). These reserves are almost completely controlled by four operating companies, United Electric and three competitors. The one virgin area of substantial size is owned by a fifth operating company. The same situation prevails in Williamson and Saline Counties. Control is in the hands of three operating companies.

Returning to your specific question, in our opinion there are not available for purchase from non-operating owners a sufficient number of adjoining tracts that when assembled would amount to strippable coal reserves over 10 million tons.

Sincerely yours,

Paul Weir

DEPOSITION
88

Availability of Economically Mineable
Strip Reserves within the State of Illinois

Report by John E. Organ, Geologist

In 1928, the writer obtained a Bachelor's degree in geology from Indiana University and a master degree the following year from George Washington University. An additional year of graduate work toward a Doctor's degree in geology was also spent at George Washington University. During both this period of formal education and immediately afterward, the writer found employment with an oil company and then with an operator of a strip mine in Sullivan County, Indiana.

Continuously since 1932, except for the war years, my principal occupation has been the exploration or acquisition for others of coal lands and mining rights. During this time, I have been responsible, directly or indirectly, for the exploitation of coal fields in the Midwest totaling hundreds of millions of tons. Mines subsequently developed from these properties include the Minnehaha mine of Ayrshire Collieries, the Buckheart Mine of The United Electric Coal Companies, the Sunspot Mine of Ayrshire Collieries in Clinton, Indiana, the Panther Mine of Green Coal Company in west Kentucky, the Shasta Mine of Binkley Coal Company, predecessor to Truax-Traer Coal Company, near Bicknell, Indiana, and the Sunspot (Illinois) Mine of Ayrshire Collieries. While these properties and others all involved strip coal, I have also been involved in the exploration or acquisition for others of deep coal within the States of Indiana and Illinois. In addition, I was instrumental in the acquisition of coal rights to approximately 750 million tons of strip coal in Wyoming and another 100 million tons in Montana.

JOHN E. ORGAN
GEOLOGIST
BRENNAN BLDG.
SULLIVAN, INDIANA

At present, I am on retainer to Ayrshire Collieries Corporation as a consultant.

At one time or another, I would estimate that I have made on-site investigations in virtually every coal producing county in the States of Illinois, Indiana and west Kentucky. I have made it my business to keep informed and abreast of developments in midwestern coal mining and attitudes and opinions of midwestern coal producers. I have also made frequent use of data periodically made available by The Illinois State Geological Survey and its counterpart in Indiana and Kentucky.

Based upon my knowledge and experience, I concluded that, by 1960, there was no longer any possibility of acquiring or establishing, for transfer to coal producers, of any new economically mineable strip coal acreage in the Illinois basin of sufficient size to justify the opening of new mines. Therefore, my subsequent activity was confined to investigation of deep coal properties in the Midwest and strip coal properties in the South and West. Within the past two years, I have, on numerous occasions, discussed the availability of strip reserves in the Midwest with a variety of coal executives knowledgeable in this field. I have also re-reviewed data released by the Illinois Geological Survey pertaining to this question. In my opinion, there remains no doubt that such economically mineable strip reserves as exist within the Illinois basin are under the control of existing producers, and that such other strip reserve acreage that has not been acquired holds no competitive promise. My own personal business decisions have, since 1960, been bottomed on this premise.

PART I - SULFUR OXIDE REGULATIONS

The effects of sulfur dioxide on human health are related to irritation of the respiratory tract. Whether these effects are acute or chronic, reversible or irreversible, depends on the length and intensity of exposure. Damage to vegetation and materials and reduced visibility also result from sulfur dioxide concentrations.

Adverse effects of sulfur dioxide on a receptor can occur from exposure to very high concentrations for short periods, such as a few minutes, or from relatively low concentrations over extended periods of time such as several months or years. Estimates of acceptable air quality for very short averaging periods are of necessity predicated on laboratory and clinical observations. For somewhat longer averaging times criteria are based on epidemiologic studies which analyze the effect of sulfur dioxide on groups of people living in a community. On the basis of intensive review of these scientific studies on the effects of time-concentration exposures to sulfur dioxide, the Department of Health, Education, and Welfare has reached the following conclusions regarding desirable air quality objectives:

> 0.1 parts per million (ppm) on a 24-hour average should not be exceeded more than one day in any 100 consecutive day period.
>
> 0.25 ppm should not be exceeded for more than one hour in any four consecutive day period.

0.5 ppm should not be exceeded for more than five minutes in any eight hour period.

The atmosphere in a polluted community usually contains a mixture of contaminants which collectively may have even greater deleterious effects on human health. Particulate matter emitted into the atmosphere is as much a health problem as is sulfur dioxide. Certain particles which are porous and have large surface areas trap sulfur dioxide gases within their pores and on their surface. These particles carry sulfur dioxide into the lungs where normally the gas would be unable to remain as an unattached molecule.

The Department of Health, Education, and Welfare has recently published two air quality criteria documents on particulates and oxides of sulfur. The fact that both were published at the same time indicated their combined importance and synergistic effects.

FEDERAL EMPHASIS ON REGULATION OF SULFUR OXIDES

From 1955 to 1965, the U. S. Department of Health, Education, and Welfare conducted several investigations of the extent of community air pollution problems throughout the country. In the midwest, extensive studies were carried out in Louisville, Kentucky, Nashville, Tennessee, and St. Louis, Missouri. Both particulate matter and sulfur dioxide levels were investigated.

As a result of these and other investigations, the Department, by 1964, began to stress the importance of sulfur oxides to the

nation's total air pollution problem.

At that time there were competing applications before the Federal Power Commission to increase the natural gas supply to Los Angeles. The most controversial issue in the case was the effect of the natural gas supply on the Los Angeles air pollution problem. It was contended by air pollution control officials and others that exclusive seasonal use of this virtually sulfur-free fuel was necessary to the health and welfare of the people of Los Angeles. The El Paso Natural Gas Company and Transwestern Pipeline Company proposed increased deliveries on an interruptible basis. Gulf Pacific proposed a less flexible 20-year fixed fuel supply. The latter was supported by the Los Angeles County Air Pollution Control District and the California Public Utilities Commission whose position was reinforced by the expert testimony of Vernon G. MacKenzie, then Assistant Surgeon General of the Public Health Service and Chief of the Federal Division of Air Pollution. Mr. MacKenzie testified that sulfur dioxide "concentrations of 10 parts per hundred million (0.1 ppm on a 24-hour average) correspond to about the lowest average concentration which has been associated with undesirable effects on humans" and that this concentration should not be exceeded more than one percent of the time. However, he maintained that there is no evidence to substantiate categorically that even this is a safe level.

Sulfur dioxide emissions became an issue at the Federal Power Commission again in 1967 when the Department supported efforts to increase the supply of natural gas to Consolidated Edison in New York. It contended that Con Ed's generating plants contributed significantly to Metropolitan New York's sulfur dioxide levels, which exceeded the 0.1 ppm criterion, and that increased use of natural gas by Con Ed would contribute to the 83 percent reduction in concentrations necessary to meet it. In this case the Commission acted favorably on the application of the supplier.

During this hearing the Department backstopped its contentions on the fuel needs of the private sector of Metropolitan New York by pointing to the stringency of the sulfur-in-fuel restrictions imposed on Federal facilities in that area which are based on the 0.1 ppm criterion.

These regulations which also apply to the Chicago and Philadelphia metropolitan areas, were promulgated by the Secretary of Health, Education, and Welfare pursuant to Executive Order No. 11282 of May 26, 1966. The order directs all Federal agencies to take steps to prevent and control air pollution from their installations.

Though the regulations take the form of emission limitations they are, in effect, sulfur-in-fuel regulations because, as the National Air Pollution Control Administration recently advised one Federal agency, current research on developing control techniques

for reducing sulfur oxides from stack gas is directed toward methodology for power-generation sources and not toward combustion units as small as those utilized in these facilities. The regulations specify that emissions shall not exceed 0.35 lbs. of SO_x per 10^6 BTU in New York City or 0.65 in Chicago and Philadelphia. The equivalent sulfur content of fuels thus required are 0.2 percent for coal and 0.3 percent for oil in the New York area and 0.45 percent and 0.6 percent respectively in Chicago and Philadelphia. (The Metropolitan Chicago counties covered by the regulations are McHenry, Kane, Lake, Cook, Dupage, and Will in Illinois, and Lake and Porter in Indiana.)

Federal facilities located outside of the three specified areas must conform to state and local air pollution regulations of the areas in which they are located or, in the absence of such regulations, must burn the lowest sulfur content fuel that is reasonably available. In determining reasonable availability, the factors to be considered include price, firmness of supply, extent of existing pollution, and assurance of supply under adverse weather and natural disaster conditions.

Another vehicle which the Department has employed since 1966 to promote the adoption of standards conforming to its recommended air quality objectives is an abatement action. The Clean Air Act authorizes the Secretary of Health, Education, and Welfare to initiate abatement procedures in interstate pollution situations and

empowers him to act when requested to do so by a state in either interstate or intrastate air pollution problems. Nine interstate and one intrastate abatement actions instituted to date include:

Selbyville, Delaware - Bishop, Maryland
Ticonderoga, New York - Shoreham, Vermont
New York - New Jersey Metropolitan Area
Kansas City, Kansas - Kansas City, Missouri
Lewiston, Idaho - Clarkston, Washington
Washington, D.C. Metropolitan Area
Parkersburg, West Virginia - Marietta, Ohio
Ironton, Ohio - Ashland, Kentucky - Huntington, West Virginia
Knox Township, Ohio - New Cumberland, West Virginia

Garrison, Montana (intrastate)

The relative stringency of sulfur-in-fuel limitations required to alleviate varying levels of existing pollution can be illustrated by considering only two of the abatement actions. In the New York - New Jersey Metropolitan Area, which has the highest ambient air levels of sulfur dioxide in the Nation, the abatement conference participants recommended the 0.1 ppm for a peak 24-hour average concentration and stringent sulfur-in-fuel regulations identical to those governing Federal facilities in that area--i.e., 0.2 percent for coal and 0.3 percent for oil. In the Parkersburg, West Virginia - Marietta, Ohio, abatement action, on the other hand, the conference participants recommended the same ambient air standard, but recommended less stringent sulfur limitations--2.0 percent on fuels burned by all existing power or steam generating plants after October 1, 1968, and 1.5 percent for all new or expanded power or steam generating plants. This, of course, reflects the fact that the sulfur dioxide levels in the Parkersburg-

Marietta area were not as high as those of New York City and the same stringency of regulation would not be required to achieve similar ambient air quality. (The Secretary of Health, Education, and Welfare has not as yet issued formal recommendations for Parkersburg-Marietta.)

In January of 1969 the Department published the first criteria documents on sulfur dioxide and particulate matter. The criteria will serve as a basis for air quality and emission standards which the states will be required to set applicable to air quality control regions. The final conclusions of the sulfur dioxide criteria document state that adverse health effects were observed when 24-hour average levels of sulfur dioxide exceeded 0.11 ppm for three to four days and advised that in promulgating air quality standards consideration should be given to margins of safety--another reference, if indirect, to the recommended 0.1 ppm for a peak 24-hour average concentration.

B. STATE AND LOCAL REGULATIONS IN THE MIDWEST

The Air Quality Act places primary responsibility for the prevention and control of air pollution at its source on state and local governments and encourages cooperative activities between them leading to uniform laws. It also encourages similar cooperation between states. However, air quality control regions shall be designated by the Secretary when in his judgement protection of public health and welfare requires establishing air quality standards.

As of June 15, 1969, 13 regions had been designated and five proposed out of a total of 57 areas throughout the country which have been identified for inclusion. Regions to be established in the vicinity of the midwest coal fields include:

Minneapolis-St. Paul, Minnesota
Milwaukee, Wisconsin

Many states and localities have commonly regulated particulate emissions. In recent years more than half of the new particulate emission ordinances have been more restrictive than one pound per million BTU hourly input, and the trend is to limits less than 0.5

pounds. The New York City requirement for 99% efficiency of particulate control equipment on bituminous coal burning units and the recent New Jersey State proposal to require the same efficiency level of all dust collection control equipment recognize the improved particulate control technology of today. The cost of highly efficient particulate control equipment is, of course, an economic factor for coal burning operations, particularly when coal of high ash content and low volatility is utilized.

Any existing sulfur oxide standards in the eleven areas listed earlier, as well as in others who act voluntarily, are subject to change and new ones will soon be promulgated. Conclusions of the document "Air Quality Criteria For Sulfur Oxides" and the stringent air quality objectives consistently recommended by the Department in the past strongly suggest that the Secretary will approve air quality and emission standards of state agencies only if they are consistent with the Department's guidelines.

Table 1 outlines the existing and locally proposed air quality standards for sulfur dioxide in the area of the midwest coal fields. These standards prescribe the exposure to this pollutant which a political jurisdiction determines should not be exceeded in a specified geographic area, and are used as one of several factors in designing legally enforceable pollutant emission standards. The table illustrates the trend to adoption of 0.1 ppm for a maximum 24-hour

TABLE 1

AIR QUALITY STANDARDS FOR SULFUR DIOXIDE IN THE AREA OF THE MIDWEST COAL FIELDS

AREA	CONCENTRATION	AVERAGING TIME - FREQUENCY
Minneapolis-St. Paul Metropolitan Area	0.02 0.10 ppm	maximum annual average 24-hr. average not to be exceeded over 1-day in any 3-month period.
St. Louis Metropolitan Area *	0.02 ppm 0.10 ppm	maximum annual average (24-hr. sampling time) 24-hr. average not to be exceeded over 1-day in any 3-month period.
Chicago Metropolitan Area ** (proposed - subject to public hearing)	Interim Goal to be Met by 1-1-72	
	0.03 ppm	maximum annual average (24-hr. sampling time)
	0.15 ppm	24-hr. average not to be exceeded more than 1% of the time.
	0.25 ppm	24-hr. maximum
	Standard to be Met by 1-1-74	
	0.015	maximum annual average (24-hr. sampling time)
	0.10	24-hr. average not to be exceeded more than 1% of the time.

AIR QUALITY STANDARDS FOR SULFUR DIOXIDE IN THE AREA OF THE MIDWEST COAL FIELDS

AREA	CONCENTRATION	AVERAGING TIME - FREQUENCY
Illinois Portion of St. Louis Metropolitan Area* (proposed-subject to public hearing)	Both 1972 interim goals and 1974 Standards are the same as for Chicago Metropolitan Area.	
East Chicago, Indiana	No person shall cause, let, permit, suffer or allow any emission of sulfur oxides which results in ground level concentration of sulfur oxides at any given point in excess of 0.5 ppm (volume) in the period of any hour and average exposure shall not exceed 0.1 ppm (volume) of sulfur oxide in any 24-hour period. These limitations shall not apply to ground level concentration occurring on the property from which such emission occurs, provided such property, from the emission point to the point of any such concentration is controlled by the person responsible for such emission.	
Gary, Indiana	Same as East Chicago	
Hammond, Indiana	Same as East Chicago	
Cincinnati (proposed)	0.2 ppm	1-hr. average not to be exceeded more than 1 time in any 7-day period.
	0.10 ppm	24-hr. average not to be exceeded more than 4-days in any calendar year.
	0.02 ppm	maximum annual average

*Madison, St. Clair, and Monroe Counties

TABLE 1 - CONTINUED

AIR QUALITY STANDARDS FOR SULFUR DIOXIDE IN THE AREA OF THE MIDWEST COAL FIELDS

AREA	CONCENTRATION		AVERAGING TIME - FREQUENCY
Kentucky State (proposed)	I, II, III, Rural, Residential, Commercial	IV Industrial	
	.04 ppm	.06 ppm	one year
	.09 ppm	.04 ppm	one month
	.18 ppm	.27 ppm	one day (24-hr) 99% (once in 3 mos)
	.32 ppm	.48 ppm	two hours 99% (once in 8 days)
	.38 ppm	.57 ppm	one hour 99% (once in 4 days)
Nashville-Davidson County, Tennessee	0.02 ppm		maximum annual average (24-hr. sampling time)
	0.10 ppm		24-hr average not to be exceeded over 1-day in any consecutive 100 day period.
Memphis, Tennessee (also proposed for Shelby County)	No person shall cause, allow, or permit any emissions of sulfur oxides which results in ground level concentrations at any point in excess of 0.5 ppm by volume for a continuous period of more than 1-hr., and the average concentration shall not exceed 0.10 ppm by volume of sulfur oxides in any 24-hr. period.		

average sulfur dioxide concentration. This standard is already in effect in St. Louis, East Chicago, Gary, Hammond, Nashville-Davidson County, and Memphis, and is proposed for Minneapolis-St. Paul, Cincinnati, and Shelby County, Tennessee.

The Illinois State proposal for its portions of the Chicago and St. Louis air quality control regions is for a 0.20 ppm maximum 24-hour average, but since the proposed standards would permit the 24-hour average to exceed 0.10 ppm only 1 percent of the time, it is essentially the same as the others. Thus, the Kentucky State proposal of 0.18 ppm for rural, residential, and commercial areas and 0.27 ppm for industrial areas is the only exception. The proposed Illinois standards are to be met by 1974, but as outlined in Table 1, it is also proposing interim goals to be met by 1972. Both the standards and goals are subject to public hearing in Chicago on August 5 and Edwardsville on August 12. The standards adopted for these two areas of Illinois could be applied statewide.

Table 2 lists current emission standards and sulfur-in-fuel regulations in the area of the midwest coal fields. Emission standards are enforceable limitations, usually based on ground-level concentrations, on the amount of a pollutant which may be emitted from any source. Sulfur-in-fuel regulations prescribe the sulfur content of fuels which may be transported into, sold, or burned in a given jurisdiction. Most recent regulations for control of sulfur oxides emissions are based on the latter. These generally correlate

TABLE 2

EMISSION STANDARDS AND SULFUR-IN-FUEL REGULATIONS IN THE AREA OF THE MIDWEST COAL FIELDS

LOCALITY	MAXIMUM ALLOWABLE SULFUR CONTENT (BY WEIGHT)	EFFECTIVE DATE
Minneapolis-St. Paul (proposed) (Less than 2,000 million BTU per hour capacity)	2.0%	Effective date of the Act (during air pollution alerts.)
(2,000 million or more BTU per hour capacity)	2.0%	Effective date of the Act (during air pollution alerts.)
	1.5%*(Coal) 2.2%*(Oil)	April 1, 1972 (during air pollution alerts.)
Cedar Rapids, Iowa (heat input of less than 1 million BTU per hour)	The lowest sulfur content fuel that is reasonably available.	November 5, 1968
St. Louis (Less than 2,000 million BTU per hour capacity)	2.0%	October 1, 1969 (applicable Oct.-March thereafter)
(2,000 million BTU per hour capacity or more)	No higher average sulfur content than the fuel or fuels used from 3-24-66 to 3-24-67	March 24, 1967
	2.2% (Oil)	March 24, 1970
	1.5% (Coal	March 24, 1970
Chicago	2.5%	July 1, 1970
	2.0%	July 1, 1971
	1.5%	January 1, 1973
Chicago (Federal Facilities)	0.6%*(Oil)	October 1, 1969
	0.45%*(Coal)	October 1, 1969
Cincinnati (Less than 200 million BTU per hour input	1.25%** on a day basis (averaged over a period of not less than one month nor more than one year	January 22, 1969
(more than 200 million BTU per hour input	new installations require policy decision of Air Pollution Board	Same

* Emission Standard

** Is deemed to comply with emission restrictions

To convert pounds of SO_2 emissions per million BTU to percentage of sulfur in fuel, place a straight-edge at appropriate number in right-hand column. Going from right-hand column to center column run straight-edge through number corresponding to the heat value of the fuel. Straight-edge then points to proper percentage figure in left-hand column. To convert percentage of sulfur in fuel to pounds of SO_2 emissions, reverse the procedure.

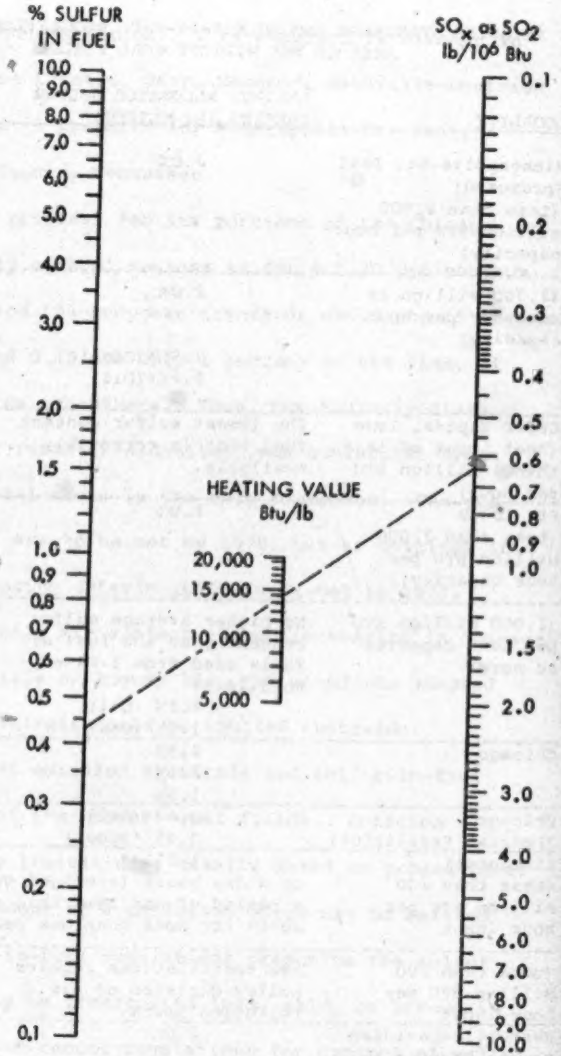

Figure 1. Nomograph for Calculating Sulfur Oxide Emissions.

evaluations of current air quality with the reduction in emissions of these pollutants necessary to obtain desirable air quality and represent calculations of the maximum sulfur content fuel which will produce emissions consistent with the required reduction. The choice of fuel within these limitations is then the province of fuel producers fuel suppliers, and fuel users. Some regulations which prescribe the sulfur content of fuels provide a discretionary clause as to fuel use so long as sulfur dioxide emissions do not exceed prescribed limits. This leaves the fuel user free to exercise other options of control if and when they are available. (In some cases the figures in Table 2 were calculated from the "Nomograph for Sulfur Oxide Emissions" (Figure 1).)

Without exception, the state air pollution control agencies of Minnesota, Wisconsin, Michigan, Iowa, Missouri, Illinois, Indiana, Ohio, Kentucky, and Tennessee report varying stages of activity in developing new sulfur dioxide standards or revising old ones at the state or local level, or both.

The Chicago City Council, last month, postponed the effective date of the first step in its three-stage sulfur-in-fuel regulation from July 1, 1969, to July 1, 1970. This step limits the sulfur content to 2.5 percent. The effective dates of the other two stages--

2.0 percent on July 1, 1971, and 1.5 percent after January 1, 1973--were not altered by this change (Table 2).

In 1968 the Missouri Air Conservation Commission agreed to postpone the effective date of the sulfur-in-fuel regulation for the non-utility market in St. Louis from that year to 1970 on the condition that Peabody Coal Company drop a suit challenging the legality of the regulations and undertake to open a low-sulfur coal mine to supply the non-utility St. Louis market. However, when Peabody announced early in June, 1969, that it was abandoning plans to open the mine, the effective date immediately was advanced from 1970 to the 1969 heating season.

The other sulfur-in-fuel regulations for smaller combustion units outlined in Table 2 show limitations ranging from 0.6 percent for oil and 0.45 percent for coal for Federal facilities in Chicago, to 1.25 percent in Cincinnati, and 2.0 percent in Minneapolis-St. Paul and Nashville-Davidson County. Cedar Rapids requires the use of fuel with the lowest sulfur content that is reasonably available.

Cincinnati's regulation is actually an emission limitation but stipulates that the use of fuels containing less than 1.25 percent sulfur on a dry basis, averaged over a period of not less than one month nor more than one year, is deemed to comply with the emission limitation. The regulations restrict the concentration of sulfur dioxide from exhaust gas to that concentration resulting

from the burning of the fuel having an average sulfur content no higher than that used collectively in combustion equipment of less than 200 million BTU per hour input rating in the City during the 24-months prior to January 22, 1969.

The proposed Minneapolis-St. Paul restrictions, contained in Minnesota State regulations currently under consideration, would apply only during air pollution alerts. Such alerts would be declared at any time the 24-hour average concentration of sulfur dioxide in the ambient air exceeds the value of 0.1 ppm, and conversion to low sulfur fuel, a supply of which users will be expected to have on hand, will be required. The St. Louis regulations and those proposed for Minneapolis-St. Paul for combustion installations with a capacity of 2,000 million BTU per hour or more are emission standards and limit the emission of sulfur dioxide to 2.3 pounds per million BTU of heat input. In the absence of control equipment with the efficiency to prevent emissions over this level, fuel oil with a maximum sulfur content of 2.2 percent or coal with no more than 1.5 percent sulfur would have to be utilized. New installations of more than 200 million BTU per hour input in Cincinnati will require a policy decision of the Air Pollution Board. (There are presently no boiler units in the City of Cincinnati fired by coal or oil having an hourly heat input of more than 200 million BTU and none projected. All larger units burn natural gas.)

It is recognized that legislative bodies often pattern laws and

regulations after those of other jurisdictions. Dade County, Florida, for instance, adopted as its own several sections of the Los Angeles County ordinance and Minneapolis was earlier proposing an ordinance very similar to that of St. Louis. Furthermore, state agencies, when faced with a similar problem in several of its communities, may promulgate rules and regulations on a regional or even statewide basis. However, projections for midwest cities or metropolitan areas which have not as yet enacted sulfur-in-fuel regulations can best be made on the basis of available information on the extent of their sulfur dioxide problem.

The 1966 density of sulfur dioxide emissions for several midwest metropolitan areas has been calculated by the National Air Pollution Control Administration. Figure 2 illustrates the rate of emissions in tons per square mile per year. The Chicago-Gary, Indianapolis, Toledo, and Louisville-New Albany metropolitan areas had SO_2 emissions in excess of 200 tons/mi^2/yr. Detroit, St. Louis-East St. Louis, and Cincinnati-Covington had emission densities ranging from 100 to 200 tons/mi^2/yr. Other cities had less than 100 tons per square mile per year or were not surveyed.

Levels of sulfur dioxide measured in the ambient air in eleven of these communities has been tabulated by the National Air Pollution Control Administration (Table 3). Results are based on National Air Sampling Network impinger samples collected at one location for 24-hours approximately once every two weeks. Results

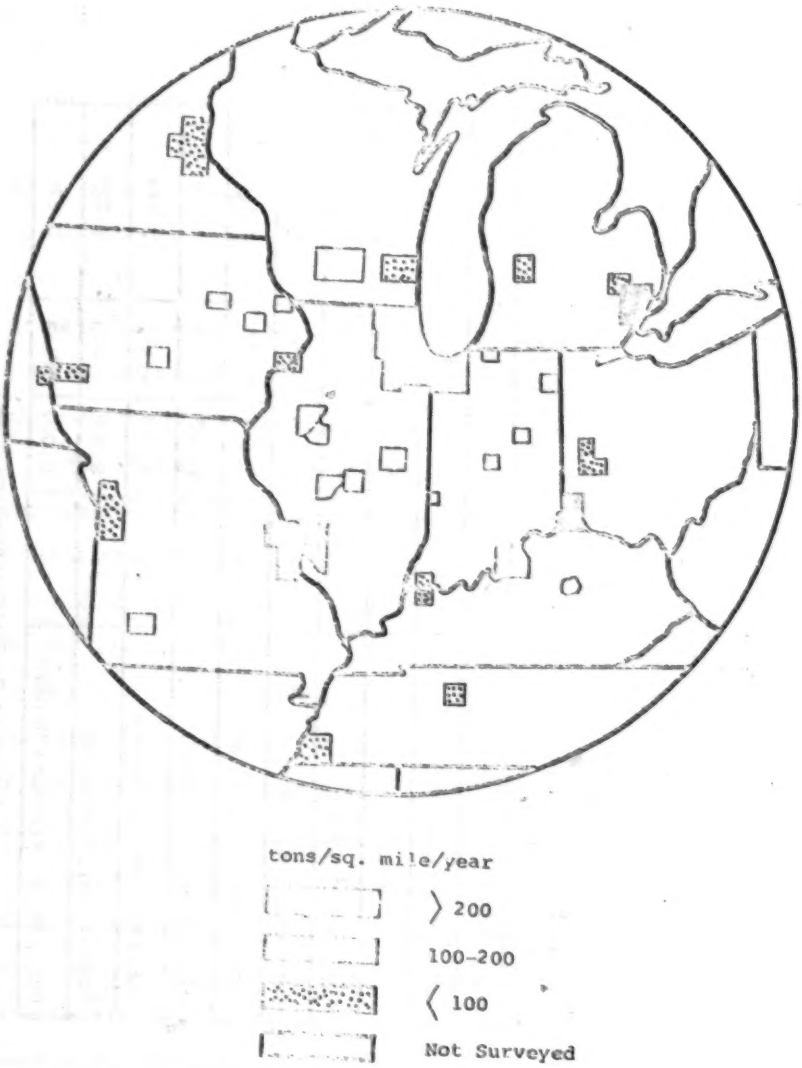

Figure 2. Estimated 1966 Emissions of Sulfur Dioxide in Major Midwest Metropolitan Areas.

are relevant to this report primarily to show relative pollution levels but are not adequate to define the magnitude or severity of a community's sulfur pollution problem.

Chicago showed the highest concentration of sulfur dioxide--some ten times that of Des Moines, Dayton, and Nashville which had the lowest levels. Intermediate concentrations, in descending order, were found in East Chicago, St. Louis, Indianapolis, Minneapolis, Milwaukee, Cincinnati, and Covington.

Within the next year or so regulations can be anticipated for air quality control regions in Milwaukee, Detroit, Indianapolis, Dayton, Toledo, Louisville, and Memphis. The emission density data and the air quality data do reflect expected similarities for communities in the entire region. For these metropolitan areas, sulfur-in-fuel limits in the range of 2.0 percent or less (or equivalent stack emission standard) can be anticipated.

For communities such as Des Moines, Davenport, Dayton, and Nashville, and other industrial centers of similar size, measured sulfur dioxide pollution levels and emission density suggest that sulfur-in-fuel limits slightly greater than 2.0 percent would suffice to provide desirable air quality. In these communities, regulations may well be promulgated to prevent gradual degradation of the existing air quality rather than allow pollution emissions to continue to increase until the standards are on the brink of being exceeded. Regulations may also be promulgated by these

smaller communities, without serious existing pollution problems, to prevent dumping of high-sulfur fuels which are banned in other areas. Also, as pointed out earlier, the State agencies may promulgate statewide regulations.

While some communities may use emission standards, a more direct approach is to limit the sulfur content of all fossil fuels to a maximum percent after a specified date. This approach is easier to enforce than emission limitations which would require expensive stack testing. Even Los Angeles with three highly qualified and experienced source test teams chose to limit the sulfur contents of combustion fuels rather than be obligated to undertake a very expensive, time consuming, and perennially controversial methodology of testing which could not be equitably and effectively implemented. Los Angeles County as early as 1958 adopted stringent sulfur-in-fuel regulations which have twice been strengthened, and which now limit sulfur content of fuel oil to 0.5 percent any time of the year.

In light of existing fuel regulations in the midwest and projections of regulations to come, the burning of coal having a sulfur content higher than 3.0 percent will be severely curtailed, if not altogether eliminated, in non-utility markets within the next ten years. Moreover, the regulatory trend, such as the existing St. Louis standards and those proposed for Minneapolis-

St. Paul requiring combustion installations with a capacity of 2,000 million BTU per hour or more to utilize 1.5 percent coal or employ efficient control equipment not yet commercially available, the proclivity of communities to pattern regulations after those of other communities, and forthcoming public consideration of new or revised regulations required for air quality control regions raise the possibility that the use of coal with a sulfur content in excess of 3.0 percent will also be severely curtailed in utility operations.

PART II - CONTROL OF SULFUR OXIDE EMISSIONS

Emphasis on sulfur oxides control technology research and development began with the Clean Air Act of 1963, continued with additional specific directions to the Secretary of Health, Education, and Welfare in an amendment in 1965, and was restated in the Air Quality Act of 1967. The latter Act requires the Secretary to "give special emphasis to research and development into new and improved methods, having industry-wide application, for the prevention and control of air pollution resulting from the combustion of fuels." The research is to be directed toward development of improved, low-cost techniques for the control of combustion byproducts and for removal of potential pollutants from fuel. Federal expenditures for these purposes have now reached a level of about $15 million a year. There are three main approaches presently being explored for reducing sulfur oxide emissions: substitution of low sulfur fuels, coal desulfurization, and flue gas desulfurization. Each of these approaches and the status of current projects are described in this part of the report.

A. SUBSTITUTION OF LOW SULFUR FUELS

One of the more obvious measures to reduce emissions of sulfur oxides is to use low sulfur fuels. Coal, oil, and natural gas exist with naturally-occurring sulfur contents low enough to satisfy sulfur oxide emission regulations, but the supplies of these fuels are limited--in the case of coal extremely so--and their availability and cost vary with geographic location.

Technology exists for reducing the sulfur content of oil and it is employed by refiners for removing greater and greater percentages of the sulfur in oil before refined products are sold. Natural gas contains virtually no sulfur and can meet any projected sulfur oxide limitation without alteration of its characteristics.

Essentially all of the residual fuel oil used in the midwest is produced in domestic refineries. Total production of this product in 1968 in PAD District II (North Central United States) was 56 million barrels. The sulfur content averaged about 1.75 percent. Thirty-three Federal facilities in the midwest reported using residual fuel oil in 1967 ranging in sulfur content from 0.4 to 8.0 percent with a median of 1.5 percent. Utilities also use residual oil but to a lesser degree. It is used by Union Electric at its Cahokia station in four of the six boilers. In 1968, 265,950 barrels were burned; this fuel had a sulfur content of 2.3 percent and the cost was $2.80 per barrel delivered (44 cents per million BTU).

Imported residual fuel oil could be put on barges at the Gulf Coast and moved to several large cities on the Mississippi River (Memphis, St. Louis, Davenport, and Minneapolis-St. Paul) or Ohio River (Louisville and Cincinnati) or other tributaries. According to a spokesman for a major oil company at the Industrial Fuels Conference held in St. Louis in February 1969, the price at the Gulf Coast is about $1.75 and allowing 60 cents per barrel for barge transportation, this fuel could be sold for $2.35 per barrel in the midwest (39 cents per million BTU). In 1968, barge movements of domestic resid via the Mississippi River from District III (Gulf States) to District II amounted to only about six million barrels. So long as new sulfur requirements are not extremely stringent (less than 1%) refiners can be expected to continue producing some residual fuel oil in domestic refineries using either domestic or foreign crude.

The Federal Power Commission has repeatedly granted authorization for increased natural gas deliveries to the midwest. The authorized supply and ready availability of natural gas to meet it have reduced coal usage in the domestic, commercial, and industrial fuel markets in the past and can be expected to infringe to some extent on the utility coal markets in the future. As an example, at the Commonwealth Edison plants in Chicago, natural gas is burned under boilers during the non-heating season for 22 to 30 cents per million BTU. The company has indicated its intention

of increasing gas consumption at its older plants located in or near the City of Chicago to help alleviate the sulfur oxide pollution problem.

A Federal Power Commission decision earlier this year allowed an additional 50 million cubic feet daily of natural gas--equivalent to 750,000 tons of coal annually--to be imported into the St. Louis market for non-utility use. This development was cited by the Peabody Coal Company as a factor in its decision to abandon the plan to open a low sulfur coal mine at Troy, Illinois, to serve the St. Louis retail market. Economics and mineability of the coal were other factors. Average values of natural gas for commercial and industrial uses consumed in the area of the midwest coal fields in 1967 are shown in Table 4.

Naturally-occurring low sulfur coal in the midwest field, (coal which can be mined and cleaned to 2.5% or lower sulfur content), reportedly is very scarce. Moreover, in existing electric utility coal-fired boilers technical and economic problems are sometimes associated with substituting low sulfur coal for the coal presently being burned. In switching from high to low sulfur coal, heat release, ash fusion temperature, and electrostatic precipitator efficiency can be greatly affected.

A recent report of the Federal Power Commission's West Central Advisory Committee stated that coal will be faced with continuing pressures as an energy source in the area. "In view

Kentucky	70.7	41.3
Tennessee	71.5	32.3

* "Field use" is use of gas for steam power generation for drilling and pumping; fuel for refineries; etc.

of the probably increasing fossil fuel costs and transportation difficulties, decreasing nuclear fuel costs, and a growing concern for air pollution," the report forecasts, "by the year 1990 nuclear fuel will account for 57 percent of the region's generating capacity and nearly 70 percent of its energy requirements."

Figure 3 shows that five nuclear power plants are operable in the 10-state area, 15 are being built, and eight are planned. The West Central region includes all of Illinois, Iowa, Minnesota, North Dakota, and Wisconsin, and substantial portions of Missouri, Nebraska, and South Dakota. In addition, it includes the upper peninsula of Michigan and small portions of Montana and Wyoming. The region accounts for about 14 percent of the population of the continental United States.

In this light, it can be concluded that the availability of natural gas in the midwest, the low sulfur content of the oil produced and refined there, and the growth of nuclear energy and mine-mouth plants will encourage air pollution control officials of the midwestern states to adopt regulations prescribing the legal limits of sulfur in fuels even though coal to meet them may be unavailable.

B. COAL DESULFURIZATION

The concept of coal desulfurization through pyrite removal, liquefaction, or gasification is not a new one. For years pyrite removal has been practiced to upgrade the quality of certain coals, increasing their value and marketability. Commercial production of artificial illuminating gas from coal was initiated about 150 years ago. Prior to and during World War II German scientists and engineers, realizing the need for alternate petroleum supplies, researched and developed commercially applicable coal liquefaction processes for producing aviation and motor gasolines, diesel fuel, and lubricants from coal. However, these processes were costly and hazardous. Desulfurization of coal in these instances was a byproduct and not a main objective. New impetus at the Federal level was given to research and development on desulfurization of coal after recent passage of several stringent air pollution regulations designed to control sulfur levels in the atmosphere. Each of these processes, their status, timing, and costs, are considered in the ensuing discussion.

Pyrite Removal

Sulfur occurs in coal in three principal forms: sulfate, organic, and pyritic. The amount of sulfate sulfur in freshly mined coal is normally small and of little significance. Organic

sulfur found in coal is more or less uniformly distributed throughout the coal substance in molecular combination and cannot be removed even partially without materially altering the nature of the coal substance. The organic sulfur content of coal generally ranges from a low of about 20 percent to a high of about 60 percent of the total sulfur. Obviously, the organic sulfur content of a coal is the prime parameter in determining whether or not significant total sulfur reductions can be made with a given coal by pyrite removal.

Since pyrite is present as a discrete particle, theoretically it can be separated mechanically from the associated coal. In most coals, however, the pyrite particles are so small and so intimately mixed with the coal that extremely fine crushing is necessary to break them apart and permit separation. Presently, this fine crushing is obtained only at utilities having pulverizers.

Bituminous Coal Research, Inc., is presently engaged in a pilot study on in-plant removal of pyritic sulfur utilizing characteristics of the pulverizer which accepts 1 1/2 in. coal, and deliver 200-mesh coal to the burners. Initial study involves optimization of pulverizer performance, seeking a maximum reject of pyrite with a minimum loss of good coal. The process will result in the rejection of a pyrite-rich fraction, with some loss of good coal which otherwise would have been burned. Additional

research by others is directed toward the ultimate utilization of the pyrite-rich coal fraction. Successful utilization can favorably affect the economics of the pyrite removal process.

As the pyrite particle size becomes smaller, the choice of cleaning becomes more difficult and costly. Furthermore, transportation of smaller sized coal particles (below about 1 1/4 inch) may lead to other problems.

Mechanical cleaning devices are divided into two general classes, wet and pneumatic, both involving a stratification effect. Depending on the quality of the final product desired, the cost may vary from 15 to 20 cents per ton for coarse cleaning without thermal drying to more than 70 cents per ton for fine coal cleaning (includes 40 cents per ton for thermal drying).

Use of chemical methods for sulfur reduction results in pyrite sulfur removal solely. With these methods, as with mechanical methods, pyrite particles must be physically separated from the coal substance before reactions for sulfur removal can be expected to take place at reasonable rates. Chemical treatment techniques are very expensive compared with the above costs of mechanical methods and it is doubtful that such exotic methods will advance to widespread commercial application. Because of the fine grinding required to expose the pyrite particles, chemical

treatment would have to be conducted at the site of use to avoid increased transportation costs. Furthermore, water used to remove the sulfates would have to be purified prior to disposal or re-use.

Mechanical and chemical methods of cleaning, at best, result only in partial removal of pyrite sulfur, itself only a fraction of the total sulfur in the coal. In the midwestern coal fields, where total sulfur content varies from about 2.0% to 5.0% and pyrite sulfur represents only 50% of this figure, coal cleaning methods which remove only a portion of the pyritic sulfur will not often result in coal quality sufficient for compliance with present or projected air pollution fuel use regulations. For example, if a coal containing 3.0 percent sulfur, 50 percent of which is pyritic sulfur, is cleaned by some process of one-third of the pyritic sulfur, the sulfur content is reduced by 0.5 percent to 2.5 percent. Therefore, for the utility coal market where long term coal contracts are common, it is doubtful that pyritic sulfur removal in itself will allow coal suppliers to meet the midwestern low sulfur fuel demands. Generally speaking, coal preparation prior to combustion will find application only where a relatively simple and inexpensive method of cleaning will remove sufficient sulfur from a specific coal to make it an acceptable fuel under terms of a particular market restriction.

Coal Gasification and Liquefaction

Technology for producing synthetic gas from coal has long been available. However, these processes produced gases with low calorific value, ranging from 120 to 600 BTU per cubic foot as contrasted with an average of 1,035 BTU per cubic foot for natural gas.

Several coal gasification processes currently under serious consideration are in various stages of development, although none is ready for commercial application. These processes are: hydrogasification, CO_2 acceptor, molten salt, and two-stage superpressure gasification.

Since 1964, the Office of Coal Research (OCR), Department of the Interior, has allocated approximately $25 million for research in this field. The American Gas Association (AGA) and the gas industry have spent about $7 million in the past 23 years supporting coal gasification research. From present development it can be readily concluded that pipeline gas obtained from the gasification of coal (presently estimated to cost approximately 40 cents to 50 cents per million BTU compared to 18 cents to 20 cents per million BTU for natural gas) will not be commercially available even on a limited basis within the next decade.

Liquefaction is not a desulfurization process per se because the sulfur is not removed and appears in the end-products which require subsequent hydrogenation treatment.

Since 1962, the OCR has allocated approximately $26 million to research and development for commercial coal liquefaction processes. These funds sponsored four projects: H-Coal Process, Project Seacoke, Project Coed, Project Gasoline.

Manufacture of synthetic liquid fuels does not promise to be a commercial reality for the next ten to 20 years, and at present most of the research in coal liquefaction is oriented toward the production of gasoline. High sulfur char, a byproduct of the liquefaction process, can be converted to a low sulfur substance with a potential to be used as a clean fuel. However, it is presently used only to generate enough power for the liquefaction process and has not been sought as a commercial fuel.

C. FLUE GAS DESULFURIZATION

First-generation flue gas processing methods which are approaching the stage where technical, engineering, and economic feasibility might be established for commercial application on large power plants include: (1) limestone injection, (2) Combustion Engineering's limestone injection plus wet-scrubbing, (3) Bureau of Mines' alkalized alumina adsorption, (4) Monsanto's catalytic oxidation, and (5) Wellman-Lord's sulfite scrubbing.

It should be recognized that about 20 years are required to go from paper studies through laboratory bench experiments, pilot plants, prototype plants, and commercial demonstration plants to commercial application. Because of this time factor, only the five first-generation processes listed earlier are considered in this report from the standpoint of technical feasibility, applicability, and economic considerations.

Limestone Injection

Technical feasibility: The least complex sulfur dioxide removal system is the introduction into the flue gas of an additive that will unite chemically with sulfur dioxide to form a solid compound. The compound thus formed can then be removed from the flue gas with conventional dust collection equipment. The use of finely-pulverized limestone or dolomite for this purpose is undergoing extensive study.

The relative simplicity of limestone injection as a means of removing oxides from power plant stack gas is a very attractive feature. The boiler serves as the reacter, no complicated regeneration system is needed, and no reheating of stack gas is required. (Figure 4)

Low degree of limestone reaction, however, is a major drawback. Unless new technology for improving sorption is developed, 24 to 35 percent utilization of the injected limestone is probably the highest attainable. Excess limestone can be used to increase sulfur dioxide removal, but adverse effect on power plant operation and cost of removing the increased dust burden from the gas and disposing of it then become major disadvantages.

A full-scale test of a limestone additive system will be conducted within the next year or so on a boiler at TVA's Shawnee Station, Paducah, Kentucky. Construction is to start this fall with several objectives:

1. Test selected limestones for sorption efficiency and slagging problems.

2. Develop an injection system that gives the proper sorbent distribution quickly.

3. Determine point and method of injection that gives optimum initial temperature level for limestone, calcined limestone, and hydrated lime.

4. Gather data on benefit of small particle size.

889

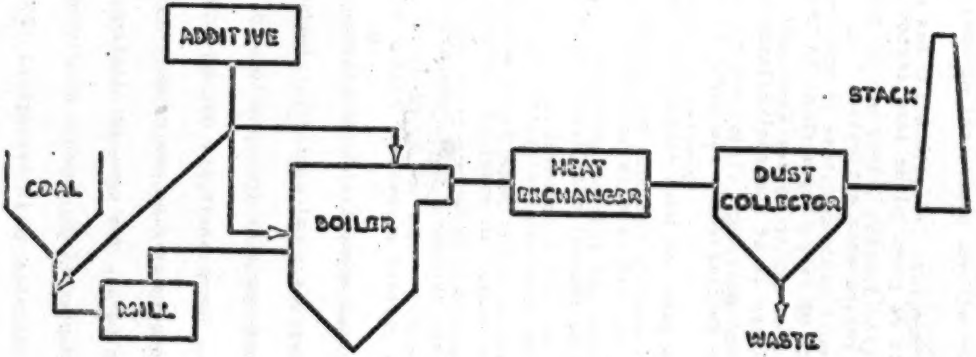

Fig. 4. Limestone Injection

5. Observe effects on power plant operation, including flame stability, heat transfer, slagging, corrosion, erosion, dust collector performance, problems in slaking calcium oxide, and water pollution.

6. Determine effect of power plant load factor on sorption.

7. Gather data to refine cost estimates.

8. Determine effect of recycling sorbent in the recirculating gas (one of the test boilers is of the recirculated-gas type).

Additive testing on smaller-scale equipment is being conducted elsewhere, but variables have not been controlled precisely, instrumentation has been lacking, and results have been erratic.

Applicability: While removal efficiency is not nearly as good as that expected from the more complex systems to be described later, the method may be useful in specific instances. Where the fuel sulfur content is not extremely high, where the plant load factor is low, or where partial removal of sulfur dioxide is sufficient to meet required ambient air conditions, the use of additives may be the most practical approach. Further, the use of additives may be the best solution for operators of commercial and industrial boilers. These units are not of sufficient size to accommodate the more complex flue gas processing systems.

Economic considerations: The cost of limestone injection, both for investment and operation, depends mainly on the amount of limestone used and the size of installation. Simply stated, however, the investment and operating costs for limestone injection

are about three and 10 percent, respectively, of normal power plant costs.

The main items in investment are the increased costs of dust-collection and waste-disposal equipment, representing about 25 and 20 percent of the total, respectively, for a 200-megawatt unit (3.5% S and 200% of stoichiometric limestone). For the operating cost, limestone (at $2.05/ton delivered) accounts for about 45 percent of the total, operation costs make up 24 percent, and capital charges 31 percent.

Conceptual design and economic studies conducted by TVA under National Air Pollution Control Administration contract indicate that the capital investment for the dry limestone injection process for an 800-megawatt power plant would be about $3 million and that the net operating cost when removing 40 to 60 percent of the SO_2 would be about $0.73 per ton. (Table 5)

Combustion Engineering's Limeston Injection Plus Wet-Scrubbing

Technical feasibility: Scrubbing of flue gases with alkaline solutions prepared from materials such as calcined limestone or dolomite, is a well-demonstrated method for removing sulfur dioxide. In one such process under development by Combustion Engineering, the additive is injected into the furnace of a boiler where it is converted by heat to calcium and magnesium oxide. (Figure 5) The oxides carry through the system with the flue gas to a turbulent

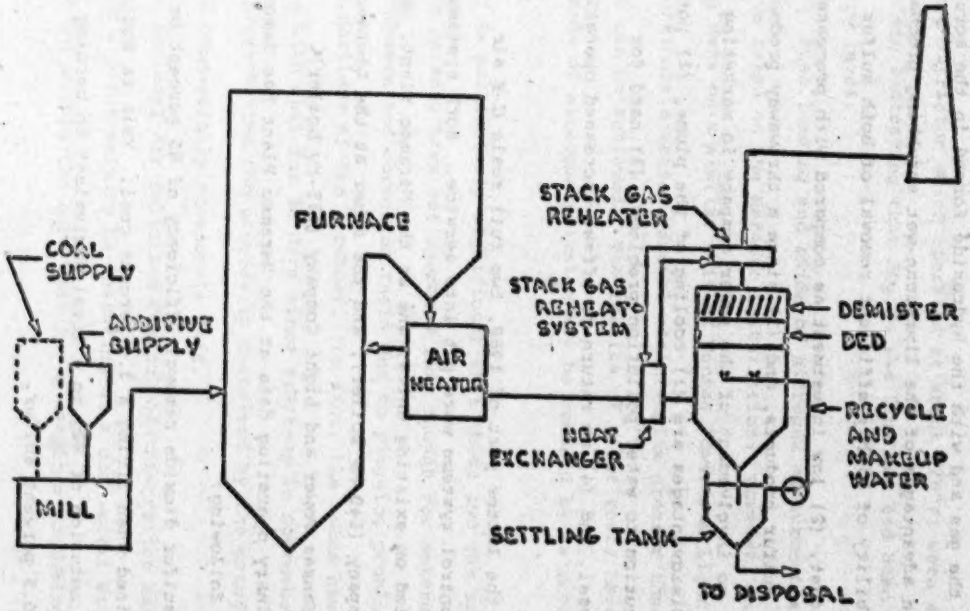

Fig. 5. Combustion Engineering's limestone injection plus wet-scrubbing.

contact absorber where, with water, they form a dilute slurry of alkaline hydroxides. Sulfur dioxide reacts both with the oxides suspended in the gas and with the hydroxide formed in the scrubber.

The main advantages of the limestone-wet scrubbing process are (1) capability of highly efficient removal of both sulfur dioxide and dust, (2) low investment as compared with processes that recover sulfur products, and (3) since a throwaway product is produced, no involvement of the power company in marketing problems. Disadvantages are (1) cooling of the plume, (2) potential contribution to water pollution problems, (3) need for solids disposal, and (4) no return to offset increased operating cost.

During the latter part of 1968, two full scale C-E air pollution control systems were put into service. Both systems were installed on existing units, one at the Meramec Plant, Union Electric Company (140-Mw boiler), and the other at the Lawrence Station of Kansas Power and Light Company (125-Mw boiler).

Preliminary operating data at the Meramec Plant has demonstrated the following:

1. A sulfur dioxide removal efficiency of 85 percent or more can be attained when firing a 3.4 percent coal. This is equivalent to reducing emission of SO_2 to a level equivalent to burning a coal containing 0.5 percent sulfur.

2. The steam generator can be operated with additive injection into the furnace. Low temperature surfaces, including the heat extractor which operated at about 220°F, were easily kept clean indicating that SO_3 in the flue gas had been reduced to a low level.

3. Dust loading and oxide of nitrogen measurements have not been taken on the Meramec installation. However, dust loading data on a similar unit at Kansas Power and Light indicate that particulate matter removal efficiencies greater than 99 percent can be achieved. The results of pilot tests have shown that oxide of nitrogen emission may be reduced by as much as 30 percent.

It is particularly significant that these two gas scrubbing units at Meramec have not operated long enough for determination of performance and corrosion tests due to plugging problems in various portions of the scrubber. In fact, the units have only operated with coal for 31 days since start-up in September 1968. At the present time the process is described by the manufacturer as not a commercially acceptable unit.

The National Air Pollution Control Administration has scheduled a pilot unit to be installed on a commercial size boiler (100-200 MW) within the next year for a wet lime scrubbing program.

(Figure 6) The test program will run 66 weeks to study additives and scrubber variables (using three scrubbers) and then will run an additional 30-50 weeks using optimum conditions for determination of erosion, corrosion, and maintenance factors. Specific variables to be studied include:

1. Variation of absorption efficiency with limestone type and with calcination conditions in the boiler.

2. Variation of absorption efficiency with scrubber type.

3. Effect of particle size on absorbent utilization. This is of particular interest for direct addition of limestone in the scrubber circuit.

4. Use of the delay tank principle in preventing scaling.

5. Corrosion in the system in extended operation.

6. Effect of oxidation promoters and inhibitors.

7. Chemical and physical properties of scrubber effluent.

Applicability: The wet process is more applicable to new plants since credit can be taken for elimination of dry dust collectors. Also the wet process requires considerably more space for waste water treatment.

The wet process becomes the basic method for comparing with recovery processes, which also are more appropriate for large baseload plants than for units operated intermittently. Because of the high and increasing cost of low sulfur fuel, limestone wet scrubbing will generally be the most economical method for sulfur

oxide control short of entering into the uncertainties and complications of recovery. In other words, for large plants the power producer likely will consider wet scrubbing unless a recovery process shows promise of being more economical--that is, a net cost sufficiently lower to make the gamble inherent in recovery processes acceptable.

Economic considerations: For a 1000-megawatt existing plant operating 8,000 hours per year and burning coal containing 3.5 percent sulfur, investment for the wet-scrubbing system (with 110 percent of the stoichiometric amount of limestone injected into the boiler and the stack gas reheated to 250°F) would more than double the investment of the dry process ($8.21/kw), but the total operating cost for continuous operation would be only slightly higher $0.90 per ton of coal. (Table 5) Since capital charges are included in the operating cost, the higher investment is not a handicap unless the unit is operated on an intermittent basis.

Bureau of Mines' Alkalized Alumina Adsorption

Technical feasibility: In the Bureau of Mines alkalized alumina process, flue gas contacts a highly-reactive solid absorbent which binds the sulfur dioxide as a sulfate. Regeneration of the absorbent for recycle releases hydrogen sulfide which is

converted to elemental sulfur. (Figure 7) Thus, the process yields a product having a definite commercial value.

The dilute phase contactor in which sorbent is entrained by the gas, separated, and then recycled offers several attractive features:

1. High gas throughput and relatively simple configuration reduce ground requirements and construction costs.

2. Pressure loss across the unit is low.

3. Flyash passes out of the sorber with the flue gas with little deposition on the solids.

4. Degree of SO_2 removal is readily controlled by variation of the recycle feed rate.

5. Minor variations in gas velocity do not affect removal efficiency.

The Bureau of Mines has recently discontinued operation of its pilot plant which burned 150#/hour of coal. A very serious problem was noticed when the scale-up was made from laboratory bench scale to pilot unit in that the alkalized alumina adsorbant (which must be regenerated for the process to be economical) was being lost during use and reclamation. This fundamental problem has resulted in a search for an improved particle form of alkalized alumina and withdrawal of research support by HAPCA.

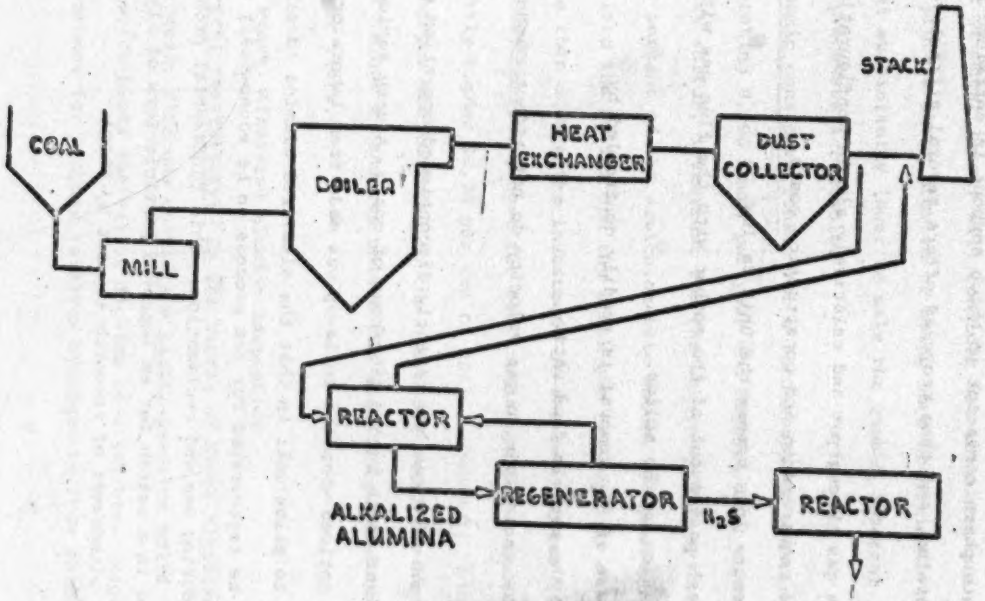

Fig. 7. Bureau of Mines alkalized alumina adsorption.

Applicability: A prototype unit and demonstration size plant would have to be operated successfully at a power plant before commercial applications would be considered.

Economic considerations: An evaluation in which capital and operating costs were estimated for removal of SO_2 from the flue gas of an 800 Mw powerplant was made by the Bureau of Mines prior to contruction of the pilot plant. It was assumed that 90 percent of the SO_2 generated by burning three percent sulfur coal with 20 percent excess air would be removed, and that the power plant would operate with a 90 percent load factor. Capital costs would total $8.5 million. The gross operating costs of $3,402,000 is equivalent to $1.54/ton of coal burned. (Table 5) Credit for recovered sulfur, at current prices, lowers the cost to about $0.50/ton of coal.

However, a recent study for NAPCA by M. W. Kellogg of conceptual design and cost analysis estimated a minimum operating cost of $3.60 per ton not including attrition loss of the adsorbent, not including generation of reducing gas, and not including the Klaus recovery plant. Because of these present economics and the technical problems, NAPCA is phasing out research funds for this sulfur oxide removal project.

Monsanto's Catalytic Oxidation

Technical feasibility: A more complex system of SO_2 removal

is catalytic oxidation. Monsanto, one of several companies researching this method, has developed a prototype system. (Figure 8) Hot furnace gases first pass through a highly efficient electrostatic precipitator (over 99.5 percent) where fly ash is removed. Gas from the precipitator is then passed through a converter where the SO_2 is catalytically oxidized to SO_3. Cooling is accomplished by using an economizer and air preheater which are designed to maintain the gas above its dew point. The SO_3 reacts with the water vapor in the flue gas and is condensed in a packed-bed absorbing tower as sulfuric acid at an average concentration of 80 percent. A mist eliminator then separates and collects the acid mist from the flue gas.

The feasibility of the Cat-ox system was established over seven years ago in a pilot operation at Pennsylvania Electric Company's Seward, Pennsylvania, generation plant. In mid-1967, Monsanto, in cooperation with Metropolitan Edison Company, began operation of a prototype plant built at the Portland, Pennsylvania, generating station. Although the facility has a generating capacity of 250 Mw, the prototype plant is designed to treat about 24,000 std. cu. ft./min. of stack gases which represents only about six percent of the total flue gas.

The major disadvantage to this process is that hot flue gases are required to produce catalytic conversion and the sulfur is

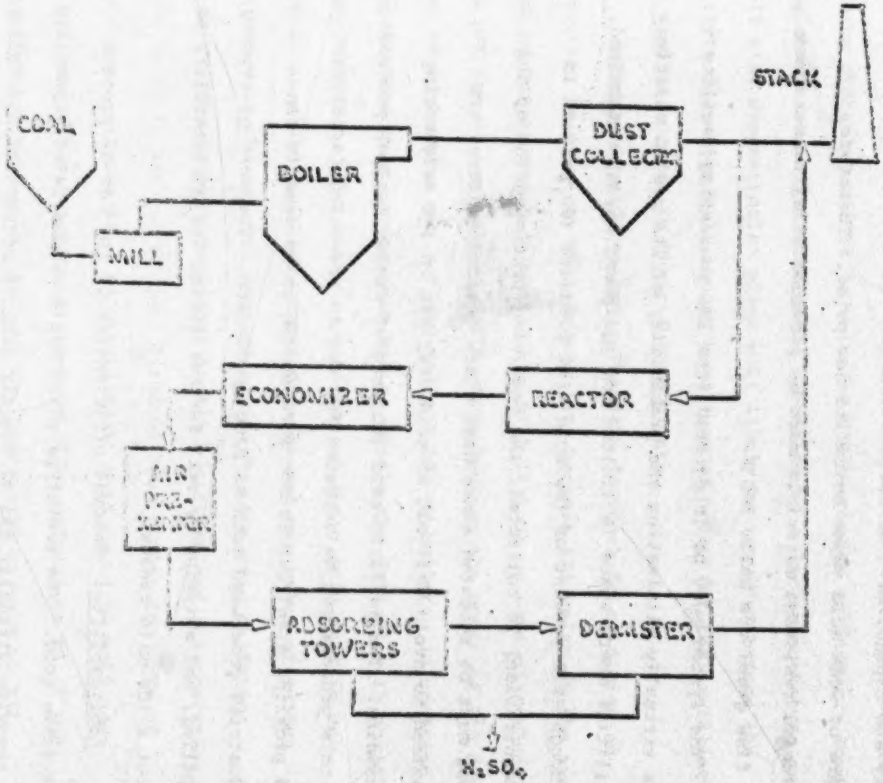

Fig. 8. Monsanto's catalytic oxidation.

removed in the form of a relatively weak sulfuric acid. High-temperature high-efficiency electrostatic precipitators are bulky and expensive. Of serious consideration is the corrosive nature of weak acid vapor below its dew point. Therefore, corrosive resistant materials must be provided in all areas where the flue gases are below 500°F.

The system must be integrated into the generating facility thus virtually eliminating the probability of its use in existing facilities where space is limited and equipment layout determined. Although 99.5 percent of the acid mist produced (80 percent in concentration) is collected, the remaining portion going up the stack must be reheated since high stack gas temperatures are required to avoid fall-out of acid droplets in the neighboring community. The sulfuric acid (80 percent concentration) produced by this process can be marketed for use in producing fertilizer and pickling steel but is not pure enough to be used in non-industrial processed such as drug production. The cost of storing, handling, and shipping by rail further limits its marketability to about a 100-mile radius.

Applicability: Removal efficiencies of the Cat-ox process are quite good. The prototype plant has a demonstrated capability of removing virtually all of the fly ash, 90 percent of the sulfur dioxide and over 99.5 percent of the sulfuric acid produced. This process would be applicable where high sulfur coal is used. In

theory, the larger the generating plant the more economical this system becomes. Projected power generating figures indicate that by 1980 a little over half the total electric capacity in the United States probably will be in units of 600 megawatts or larger. However, the construction and successful operation of a larger prototype or full size demonstration plant will likely be required before the utility companies will invest huge sums of money for the installation of similar systems in their future plants.

Economic considerations: The main drawback to oxidation or reduction in place is high investment, because all units of the system must be large enough to handle the full 12 tons or more of combustion gas per ton of coal burned, or a throughput on the order of 110,000 tons of combustion gas per day for a 1,000 Mw boiler. In contrast, only the absorber or scrubber has to handle the full flow in sorption-type processes. The netback price for sulfuric acid sold is dependent on plant location, local demands and the value of sulfur. For example, the capital cost of an 800 Mw catalytic oxidation installation has been estimated at $16.5 million and the operating costs at $1.75 per ton of coal fired without credit for sale of byproduct. (Table 5) If the sulfuric acid could be sold for $9 per ton, the net operating cost would be reduced to $0.72 per ton of coal fired or to $0.38 if the acid could be sold at $12 per ton. However, the fluctuation in acid prices and the

uncertainty of the long-term market detracts from its strongest selling point--namely, the full or partial recovery of operational costs through the sale of sulfuric acid.

Wellman-Lord's Sulfite Scrubbing Process

Technical feasibility: The highly secretive Wellman-Lord sulfur dioxide recovery process reportedly represents a new approach in the field of air pollution control; however, it bears some similarity to the catalytic oxidation and the aklalized alumina process. (Figure 9)

In this process the sulfur-laden flue gases are first cleaned in a high-temperature high-efficiency electrostatic precipitator and then passed through a noncatalytic reactor which is continuously washed by a reactive solution. The residual particulate matter and sulfur trioxide adhering to it are trapped in the solution and removed by a continuous blowdown. The sulfur dioxide is disolved in the process solution which is sent to a stripping column where steam is added to release the sulfur dioxide as a wet gas of very high purity. The wet SO_2 vapor is compressed and recovered as pure liquid SO_2 from a rectification tower.

The process was only conceived in mid-1966 and a pilot plant was installed early in 1968 at the Cannon station of the Tampa Electric Company where it is in operation at the present time. A 23 MW plant processing 60,000 ACFM flue gas was started up early

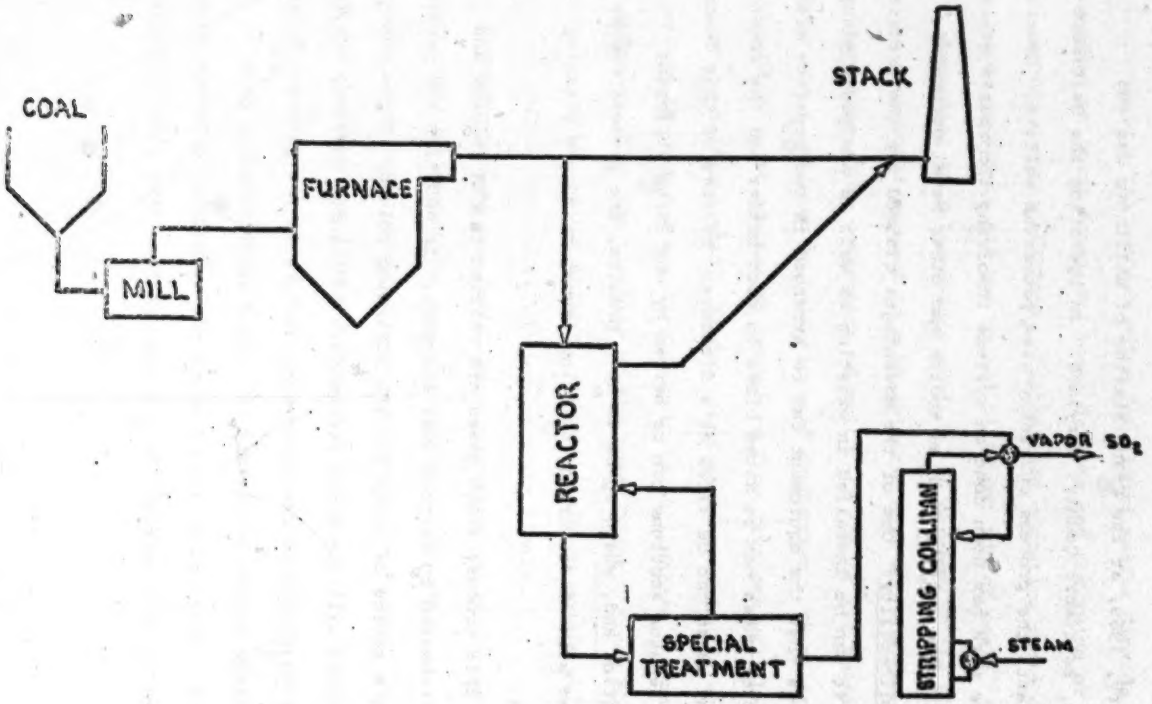

Fig. 9. Wellman-Lord SO_2 Recovery Process.

in January, 1969, at the Crane station of Baltimore Gas and Electric, Baltimore County, Maryland. In operating the Baltimore pilot plant, the process currently uses potassium sulfite. However, extensive work has been done on systems involving absorbants other than potassium sulfite such as sodium and other metal compounds.

Applicability: One of the advantages claimed for the process is that it can be installed in existing as well as new power plants. Another is that the equipment can be arranged in two separate areas. The reactor phase can be sited close to each boiler and the chemical stripping phase can be sited at a distance. Because of this feature several reactor sections can be served by one large stripping installation and, where space is at a premium, the process can be installed without disturbing existing layout or future planning programs.

In this process stack gases are chilled in the reactor and must be reheated to restore lost buoyancy. In addition the process requires a source of steam for the stripping column. These energy requirements will therefore necessitate additional auxilary boilers in existing plants or oversized main boilers in new plants. Another disadvantage is the production of liquid sulfur dioxide as a byproduct. Most utility managements are reluctant to become engaged in marketing this product for the same reasons they dislike marketing

sulfuric acid. The netback price for liquid sulfur dioxide is dependent on plant location, local demands and the value of sulfur.

Economic considerations: Capital and operating costs are estimated at $10 to $11 per Mw and $1.49 per ton of coal. (Table 5)

According to Wellman-Lord studies, 85 percent of the sulfur in the free world is used to make sulfuric acid and the percentage is increasing. The conversion of sulfur to SO_2 or the receipt of SO_2 is the first step in sulfuric acid production. Thus, it is assumed that most of the SO_2 recovered from flue gas will be used to produce sulfuric acid. As described earlier, sulfuric acid is expensive to ship and may be difficult to sell unless it can be disposed of in the vicinity of the power plant. Since the process is still in its infancy, further scale-up models will be required before commercial applications are likely.

Within the next ten years, many processes for sulfur oxide removal will be tested and further developed. However, it is unlikely that many commercial applications will be made. Of the five first-generation flue gas desulfurization methods discussed in this report, two (wet and dry limestone injection) do not produce usable byproducts whereas the remaining three produce various sulfur bearing byproducts. For continuous operation in base load plants the wet scrubber is more desirable due to its

higher efficiency of sulfur oxide and dust removal. For existing small generating plants the dry limestone injection offers more potential. However, both processes are still being developed by the National Air Pollution Control Association and many questions remain to be answered before commercial applications can be expected.

When comparing the three flue gas processing methods which produce a byproduct, the Monsanto cat-ox system is considered technically ahead of the other two. It is, by far, the most expensive to install and operate even though all three require heavy capital expenditures. Also all three methods produce a sulfur byproduct that would force the steam-electric utility's management into becoming chemical producers. Since sulfur and sulfuric acid prices constantly vary, utilities are not likely to readily accept these processes. The alkalized alumina process in theory is very promising since its proposed byproduct is elemental sulfur. However, this method developed serious problems when tested at the pilot plant level and development work has been drastically reduced. The Wellman-Lord Sulfite Scrubbing process seems the most economical but this process is still in its infancy and will require years of testing from its present small scale facilities before commercial installations will become reality.

Over the long term, it is reasonable to expect that planning for large new steam-electric plants will consider the need for

reducing sulfur oxide emissions as well as for removing particulate matter which is common today. Such planning will likely take into consideration the economics of alternate fuels, alternate fuel cleaning procedures, and stack gas cleaning methods.

CONCLUSION

In sum, coal consuming facilities in most industrial areas in the midwest will be increasingly forced to take positive action to control or indeed eliminate sulfur oxide emissions. For many, conversion to other fuels will represent the only practical means of compliance. For other energy users, the cost and time tables of abatement strategies discussed in this report will be carefully weighed before final decisions are made as to fuel or energy source and location of facilities. Over the next 10 years, air pollution limitations will have a serious impact upon coal's marketing patterns and its share of energy markets. Beyond that period, such limitations may well continue to constitute an important competitive handicap to coal's ability to compete with other energy sources.

868

How to preserve our air, water and land is the question of the day. Our public is concerned and so are we. We also are concerned in the public interest about an adequate and uninterrupted supply of energy. We know from experience that the public demands it.

Because of these concerns I feel I should give you my views as to how electric power supply should be handled in the long-term future to minimize intrusion upon our environment.

First, large generating complexes should be located away from urban areas. These complexes can make use of several power sources. They may be fossil-fired, present-day nuclear machines, or breeder or fusion reactors. Nuclear units and their successors will be in every way fine neighbors. Quiet. Absolutely safe. No long strings of coal cars. Not a trace of smoke or soot. And designed to satisfy tough water temperature standards.

These generating complexes should be linked to each other and to city and industrial load centers. The result will be a grid with stations and transmission lines of great capacity.

Huge power demands require big units and big interconnecting lines. Even with our present technology we are building them with almost no adverse ecological effect. Fortunately, such a bulk power system is not only the most reliable but also the most economical. This means smaller power systems may increasingly choose not to make their own electricity, but instead to buy it from larger complexes built by larger companies. Law and custom may resist this, but technology, economy and environment may require it.

In our business, we must plan and begin construction years ahead of need. To anticipate public wishes in a timely way, we can accent one or another of the environmental alternatives which technology and economy allow. But stations cannot be rebuilt overnight. New nuclear units do not spring magically from the ground. Fuel sources take time to develop and to modify. Nevertheless, we have done much quickly, and we shall do more soon. We will eliminate our share of pollution in just as short a period as meeting our electrical commitments to the people of Illinois will allow.

And there is no doubt in my mind that we will furnish power in the future in a way that makes northern Illinois a better place in which to live.

Sincerely,

J. Harris Ward
Chairman

1969 Review

Earnings, dividends flat
Our earnings for 1969 were $3.00 per common share, virtually unchanged from 1968's level of $2.99 or 1967's $2.98. Net income on common stock totaled $126 million, about the same as that of the prior year.

Dividend payments during 1969 were $2.20 a common share, the same as in 1968, and only 10 cents more than in 1967. This leveling off in earnings and dividend growth contrasts with good increases in the preceding years.

Stockholders are entitled to a competitive return on their investment. To supply this and to compete effectively in the money markets, we require a rate increase.

Good sales performance
This need for rate relief is not caused by lagging sales growth. During 1969, each of our four major classifications of kilowatthour sales and revenues had fine increases. Electricity sales to ultimate consumers increased 6.1 percent over 1968, and related revenues had a 7.8 percent gain. These compare with average annual increases of sales and revenues during the 1960's of 7.4 and 5.4 percent. It is nice to close out the soaring sixties with increases which are well above average for the decade. We are confident about Edison's ability to continue to increase—at a good pace—its sales and revenues during the 1970's.

At December 31, we had 2.54 million customers on our lines, 2.2 percent or 55 thousand more than at the end of 1968.

1969 Revenues and Sales	Electric Operating Revenues (thousands)	Increase Over 1968	Kilowatthour Sales (millions)	Increase Over 1968
Residential	$303,981	7.9%	11,835	9.2%
Small commercial and industrial	286,199	6.0%	13,378	6.6%
Large commercial and industrial	139,443	10.2%	13,781	9.4%
Public authorities	48,050	9.0%	3,988	8.8%
Electric railroads	5,355	—	385	—
Ultimate consumers	$783,028	7.8%	42,933	8.1%
Sales for resale	9,767		1,454	
Other revenues	7,754			
Total	$801,149		44,387	

Expenses up $47 million
Electric operating expenses during 1969 totaled $426 million, $47 million or 12.4 percent higher than last year. $26 million of the increase was due to higher fuel and purchased power expenses. This was a result of having to buy higher cost fuel and more of it, and—among other purchases—of having to import power to cover Dresden 2's delay.

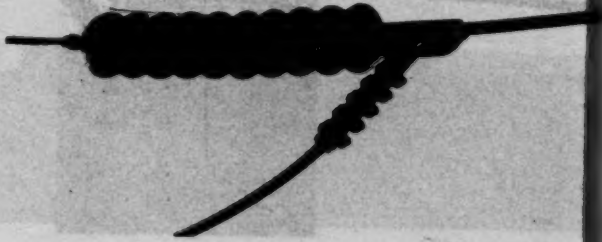
Other operation and maintenance increased $12 million or 7.6 percent, due mainly to higher payroll costs. Added plant pushed depreciation expense up $7 million or 7.4 percent.

Taxes cut earnings
During 1969 we paid or set aside $207 million in state, federal and local taxes of all kinds and sizes.

A burdensome new 1969 tax was the Illinois income tax, levied at 4 percent for corporations. The state income tax was effective on August 1 and cost stockholders 3 cents per share on 1969 earnings. We estimate the 1970 effect to be on the order of 8 cents. On the other hand, reduction in the federal income tax surcharge should help to offset 1970 increases in taxes and other operating costs.

1969 Electric Operating Expenses	1969 (Thousands)	Increase Over 1968
Fuel and purchased and interchanged power (net)	$154,381	22.2%
Other operation and maintenance	170,615	7.8%
Depreciation (straight line)	100,941	7.4%
Total	$425,937	12.4%

Power for People in the '70's is the theme of this report. Edison facilities, like this strain insulator, tie together the vital activities of northern Illinois. Shown here are a man on Ford's Chicago assembly line, one of our nuclear plants under construction, and Amoco's refinery near Joliet.



Interest costs jump 28%
Interest charges on debt during the year were $62 million, up $13 million or 26 percent over 1968. This big increase was due to new bond issues and interim short-term financing at record-breaking interest rates. Regardless of capital costs, we must raise the money required to carry out our construction program. We expect another sizeable increase in interest costs during 1970.

Progress on rate request
On August 15, 1969 we filed with Illinois Commerce Commission proposed new rates which provided for a 6.1 percent revenue increase. The Commission must render a decision within 11 months of initial filing or, in our case, by July 13, 1970. We, of course, hope for an earlier ruling and are doing all we can to hasten the hearings.

Under Illinois law, we are entitled to rates which give us the opportunity to earn a fair return upon the fair value of our plant. Establishment of fair plant value involves among other things "the fair consideration of current price levels, . . . the ultimate purpose being to determine and allow a fair return to the owners . . ." Fair value is less than today's replacement cost, but it ought to be substantially more than original cost. In these inflationary times, fair value is a far more just standard than original cost.

We do not like rate increases because they impair our ability to compete in the energy market. Indeed, in the 1960's we reduced our customers' rates time after time. However, inflation has more than counterbalanced our cost-control efforts, and we have reluctantly applied for a rate increase.

Why rate relief vital
The captions in this annual report tell the story: "Earnings, dividends flat", "Expenses up $47 million", "Taxes cut earnings", "Interest costs jump 56%", "Plant budget up $250 million", "$386 million for 1980 construction", "$1 billion of new securities needed", "Wages up 6%, benefits higher". The pressures of rising expenses are heavy and have in turn leveled our earnings.

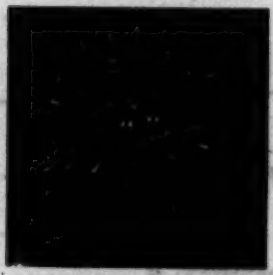
Our business is growing rapidly and we must expand our facilities to serve it. But since 1963, our generating station construction costs per kilowatt have risen by up to 80 percent, and interest rates have nearly doubled. We must meet expanding load commitments with far more expensive new facilities. The result is the largest construction budget in our history which must be financed at near-record interest rates.

Today's investors require far higher returns than they once did, and we must pay their price to use their money. To attract capital we need greater earnings. In short, we need a rate increase.

A modest request
A 6.1 percent rate increase request is modest. Other electric power companies around the country have asked for far more. We did not request 6.1 percent in the hope of getting something less. Instead, we asked only for the amount we must have, and we hope to receive that amount in full.

Preserving Lake Michigan
Clean air and water is an idea whose hour has come. The center insert of this report outlines what Edison is doing to reduce pollution. We are deeply concerned, and recognize that others are, too. Not all concerns, however, have equal basis in fact, and a recent example of this has to do with Lake Michigan.

These finely machined control rod drive housings in an Edison nuclear plant help provide electricity to people in farms and homes across our 13 thousand square mile service area.



Zion safe for lake
Two suits were brought last fall to halt construction of our Zion Nuclear Power Station. Each claimed that Zion would damage Lake Michigan. Zion Station will not harm Lake Michigan.

Zion Station is being built under rigorous Atomic Energy Commission standards. The water returned to the lake at Zion will be safe. In fact, insofar as radioactivity is concerned, one could drink it for a lifetime without harm.

Our extensive studies indicate that fish and plant life will not be injured. Indeed, one of the best fishing spots in our area is off our Waukegan plant, south of Zion. The amount of water passed daily through Zion's sealed condensing system will be roughly equivalent to circulating one pint of tepid water in a good sized swimming pool.

The temperature of the water returned to the lake will be under 85 degrees, meeting the limits set by the State of Illinois and approved by the U.S. Department of the Interior. Indeed, the Federal Water Pollution Control Administration has stated that the combined annual effect of all existing plants plus all proposed nuclear plants on Lake Michigan would raise overall lake temperature by less than 1/10th of one degree Fahrenheit. Even this small rise tends to cancel out each winter. Interestingly, the average annual temperature of the lake has actually dropped about two degrees in the past century.

Gas negotiations begin
In December, Edison made a joint announcement with Northern Illinois Gas Company that negotiations were under way for acquisition of our subsidiary, Mid-Illinois Gas Company.

We have been approached by several companies in addition to Northern Illinois. Since we have a valuable commodity, we expect to be able to make an agreement which is fair to our stockholders, protects our gas employes, and is in the public interest. We anticipate that arrangements will be completed during 1970.

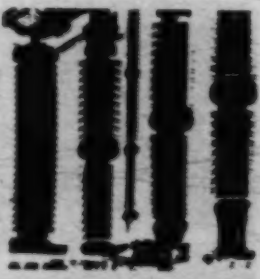
CILCo merger talks ended
During 1967 and 1969, we conducted talks with Central Illinois Light Company on the possibility of merger with Edison. In June, 1969 we made an offer which would have allowed CILCo's common stockholders to elect securities giving them premiums of over 85 percent on income and 25 percent on market price. In October, CILCo's management rejected our terms and broke off negotiations. We do not expect the talks to be reopened.

Peak summer load
A record peak load of 8.3 million kilowatts was set July 16. This was only a 3.5 percent increase over 1968's highest load, compared with an unusual 17 percent rise between 1967 and 1968. Because of the variability of summer weather, we have come to expect that heat sensitive loads will not march evenly upward year after year.

On the average, however, our summer peak loads are growing at over 8 percent each year. To meet them our engineers, purchasing and construction people must plan, buy, build and bring into effective service hundreds of millions of dollars worth of new plant each year. The range between extravagance and perfect investment economy on a system the size of Commonwealth Edison's must surely exceed several hundred millions of dollars. For example, last fall a national magazine estimated that by purchasing four nuclear units at fixed prices Edison had saved "about $300 million."

Fast-start peaking units
During 1969 we placed on our system 535 thousand kilowatts of fast-start peaking capacity, bringing our total of such equipment to 1.34 million kilowatts, more than any company in the country. An additional 360 thousand kilowatts have been ordered for 1970 service, though about 200 thousand kilowatts may miss the summer peak due to the General Electric strike.

Homes are heated with the help of these insulators at one of our 135 transmission substations.



Generating capacity additions

Unit	Type	Scheduled for	Net Capacity (kilowatts)
Dresden 2	Nuclear	Spring '70	809,000
Peaking	Gas & Oil	Spring, Summer '70	360,000
Dresden 3	Nuclear	Winter '70-'71	809,000
Quad-Cities 1	Nuclear	Spring '71	809,000*
Quad-Cities 2	Nuclear	Spring '72	809,000*
Zion 1	Nuclear	Spring '72	1,100,000
Powerton 5	Coal	Spring '72	840,000
Zion 2	Nuclear	Spring '73	1,100,000
None	—	'74	—
None	—	'75	—

*Iowa-Illinois Gas and Electric Company has a one-quarter ownership interest in the two Quad-Cities units.

These machines are economical for meeting short periods of peak demand because their low capital costs offset their higher fuel costs. They burn gas or oil and can be brought on line in small increments on short notice. Perhaps best of all, the fast-start units allow us to retire smaller coal-fired boilers around the City of Chicago, and thus contribute to our efforts to curb air pollution.

First big nuclear unit

This spring Dresden 2, the first of our large second generation nuclear units will be placed in commercial service, and should be starting up as you read this report. Dresden 2 has an ultimate capacity of 809 thousand kilowatts and will be followed within about a year by two more nuclear units, Dresden 3 and Quad-Cities 1.

These plants must meet rigorous construction standards before being granted an operating license by the Atomic Energy Commission. Because of the care with which they have been built, we expect them to be absolutely safe, and more reliable than any of our large coal-fired units. Nuclear units produce electricity without smoke, soot or dust, and are, therefore, the keystone of our clean air program.

Pumped hydro power

Nuclear generation also fits well with pumped hydro generation. We are negotiating with Consumers Power and Detroit Edison for a 624 thousand kilowatt share of their Ludington, Michigan pumped hydro generating plant. It would be purchased under a long-term agreement beginning in 1974.

Electrical demands are lower at night and so nighttime energy is most economical for us to produce. During the night, energy from our nuclear units would be employed to pump water to an elevated storage reservoir on the eastern shore of Lake Michigan. During daylight hours the water would be released, electricity generated, and the energy returned to us over high voltage transmission lines.

Skilled people controlling intricate machines—computers, airplanes and Edison junction boxes—make our electrified urban society possible.

On average, about three off-peak kilowatthours would be used up for every two on-peak kilowatthours generated. However, high daytime and low nighttime demands plus around-the-clock loading of our nuclear machines make the transaction an economic one. Also, this and other power purchase agreements will allow us to forego construction of any major generating units for 1974 and 1975 service.

In the nearer term, purchased power contracts, strong interconnections, our fast-start peaking units, and the larger units coming on in the early 1970's should provide adequate reserve margins for meeting the needs of our northern Illinois service area.

Plant budget up $200 million

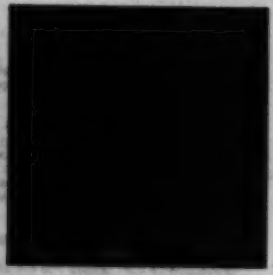
For electric generating units, transmission lines, distribution facilities and other plant, we plan to spend $1.95 billion during the five years 1970 through 1974. This compares with $1.7 billion budgeted for the period 1969–1973.

The increase from $1.7 to $1.95 billion for the different budgeting periods results in part from the strong sales growth we expect. However, inflation and environmental considerations also play their parts.

The new $1.95 billion budget includes expenditures of $320 million in 1970, $470 million in 1971, $305 million in 1972, $280 million in 1973, and $375 million in 1974.

The totals after 1971 are somewhat lower than they would otherwise be because no major generating units are scheduled to begin service in 1974 or 1975. Allowance has been made, however, for initial outlays for construction of 1976 and 1977 units.

A man involved in his work and a steel furnace ladle are both served by graceful 138 thousand volt transmission lines.



Air Pollution in the Chicago Area

What Commonwealth Edison is doing to help reduce it, and what we will do, and when.

"... everybody—beginning with ourselves—must do more to make our city, our nation, our world, a better, brighter, sweeter (and not just richer) place for us and our children to enjoy."

Air pollution is a serious matter, for all citizens in every city, in every developed country in the world.

It is too serious to become a political football, or an emotional and partisan issue, or a platform on which companies can thump their chests and proclaim their virtue and good citizenship. Deeds, not words, are what the public is looking for—and has a right to get.

Commonwealth Edison has already spent $63 million on facilities to prevent contaminants from getting into the air; and is spending hundreds of millions on new nuclear stations which add *no* fumes or dirt to the air.

But it is beside the point that we have spent "x" millions of dollars, and committed millions more.

What *is* important is not so much what we have done as what we will do. We recognize the gravity of the problem, and accept the plain fact that everybody—beginning with ourselves—must do more to make our city, our nation, our world, a better, brighter, sweeter (and not just richer) place for us and our children to enjoy.

The Rules We Live By

Years ago, Commonwealth Edison decided that we had these obligations to the community:

1. To provide the amounts of electricity needed, where needed and when needed, within the area we serve, and reserve margins to handle emergency conditions.

2. To do this at the lowest possible cost to the consumer.

3. To anticipate future needs, often involving years of lead-time for the manufacture and installation of necessary facilities.

4. To do all this while minimizing actual and potential pollution.

". . . the waste particles which people call 'smoke' can be almost entirely prevented from escaping into the air . . ."

Electric Power and Air Pollution
Commonwealth Edison produces and distributes the electricity on which practically every home, office, store, and industry in our entire area depends.

Our product heats and air-conditions the 100 story John Hancock Center and runs the elevators that make such a building possible. It lights your home, operates your TV set, and may even brush your teeth.

Electricity must be always on tap, day or night, at the flick of a switch. It can't be stored until you need it. Most people have come to take it for granted.

How does Commonwealth Edison produce electricity? Chiefly by heating water in giant boilers to make steam power, which turbines and generators convert into electric power.

We have three types of boilers: coal-fired, natural gas or oil-fired, and nuclear-powered.

Nuclear reaction emits no fumes or smoke. Natural gas or oil burning releases some, but not much. Coal burning releases more, including sulfur oxides, but the waste particles which people call "smoke" can be almost entirely prevented from escaping into the air by the use of modern electrostatic precipitators.

Before
This stack at our Joliet Station has its electrostatic precipitator disconnected to show how much smoke would escape.

After
Soon afterward this unretouched photo shows the unit still in full operation—but with its modern precipitator connected.

". . . we account for less than 5 percent of all contaminants in the air you breathe."

Our Plan of Action
1. To cut in half, within the near future, the amount of coal we burn in and around Chicago, and then to reduce it still more.

2. To continue to improve our electrostatic precipitators. Our goal is to try to have every precipitator prevent 98 percent or more of waste particles from the coal we burn from getting into the air.

3. To increase as rapidly as possible the share of nuclear power in our total production.

4. To use all the natural gas we can get. To introduce new low-sulfur oil. And to continue our efforts to obtain and burn low-sulfur coal.

Here are details of our Plan of Action:

1. We Are Reducing the Amount of Coal We Burn
The best way for us to help reduce air pollution is to burn less coal. This is not easy when the demand for electricity continues to grow.

Still, this is what we are achieving:

	Coal (million tons) burned in Chicago area	Electricity (billion kwh) used in Chicago
1965	8½	14
1970 (Est.)	4	18
1975 (Est.)	3½	24

These reductions are made possible in part by our nuclear program and by converting an entire generating station from coal to low-sulfur oil.

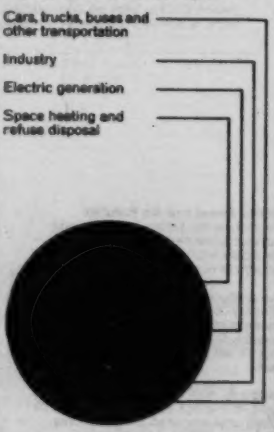
Also, within the last two years we have installed 1.24 million kilowatts of fast-start generating units (another 360 thousand in 1970), which burn only gas or oil and will permit retirement of an entire Chicago coal-fired station.

2. We Are Installing More and Better Precipitators
Commonwealth Edison began installing precipitators as long ago as 1929. They have been steadily improved to reach their present levels of efficiency. The newest electrostatic precipitators prevent all but a small amount of the "particulates," or waste particles from the coal we burn, from getting into the air.

All coal-fired boilers in our metropolitan area stations are equipped with precipitators. We have a few precipitators left that are not yet 98 percent efficient, but we're working hard to finish upgrading them.

We have retired 47 coal-fired boilers in Chicago within the past ten years. We presently plan to have only nine left in Chicago by the end of this year.

Sources of Air Pollution
The principal sources of air pollution nationally, according to an authoritative report by the National Academy of Sciences ("Waste Management and Control"), are about as follows:



These are national figures. In the case of Commonwealth Edison, although we burn two-thirds of all the coal burned in the Chicago area, our control and dispersion methods are so effective that we account for less than 5 percent of all contaminants in the air you breathe. Included in this 5 percent figure are sulfur oxide emissions. Most of the ground-level sulfur oxides come from homes, stores, factories and apartment buildings which lack the tall stacks of our stations.

"Commonwealth Edison is complying, and will continue to comply in full, with all government laws and regulations on air pollution . . ."

3. We Are Rapidly Increasing Our Nuclear Production of Electricity
Commonwealth Edison pioneered in the development of nuclear power nearly 20 years ago. Our first nuclear unit has been operating successfully at Dresden for ten years.

We now have six large nuclear units under construction, two each at Dresden, Quad-Cities and Zion.

The first is scheduled to be in operation this spring. All will be in operation by 1973.

About 40 percent of our vastly greater production of electricity will then be from nuclear stations, which emit no fumes or smoke. Our $600 million nuclear program is the largest of any investor-owned electric power company in the United States.

4. We Are Using Natural Gas and Low-Sulfur Oil, Testing Low-Sulfur Coal, Researching the Removal of Sulfur Oxides
Natural gas is available to us only in limited quantities. We are using all we can get.

We recently announced the 1970 conversion of our Ridgeland Station (in Stickney, Illinois, immediately west of Chicago) to low-sulfur oil-burning equipment. Ridgeland was chosen because its stacks must be lower than those at other stations due to its nearness to Midway Airport.
This conversion alone will eliminate the burning of 1.3 million tons of coal a year.

Another way to reduce air pollution is to use coal with low-sulfur content. There is low-sulfur coal in Montana, Wyoming, and Colorado, and we have been testing it. We haven't yet found any we can burn successfully, because our boilers and precipitators were not designed for it. Eastern low-sulfur coal appears to present even more severe problems. But we continue to test.

Clean-Air Pellets: Each of these tiny nuclear pellets contains as much energy as a ton of coal. They produce electricity without any fumes, smoke or soot.

We have long participated in efforts to develop advanced methods of removing gaseous sulfur oxides from stack gas. Recently we have joined with 15 other electric power companies, Esso Research and Engineering Company and Babcock & Wilcox Company in a $7 million program for the development of an advanced air pollution control system of this kind.

Commonwealth Edison is complying, and will continue to comply in full, with all government laws and regulations on air pollution, including Chicago's Pollution Control Ordinance.

This ordinance, effective in July, 1970, requires that sulfur emissions be lowered in progressive steps through 1974. The ordinance can be complied with either by burning less coal or lower sulfur coal.

We are following the first route, by cutting our coal burn in half, and we will meet the timetable of the ordinance.

This is better than just cutting the sulfur content of the coal because all combustion products are reduced. The ordinance requires approval of our plan to do so, and we have applied for this.

$396 million for 1969 construction
During 1969 construction expenditures were $396 million and plant retirements and adjustments $30 million. Our gross investment in plant and equipment at December 31, was $3.7 billion. In addition, our nuclear fuel investment totaled $71 million.

$1 billion of new securities needed
In the five years 1970–1974, about $1 billion of new securities must be sold to help pay for new construction and nuclear fuel. This is in addition to our January, 1970 bonds and refunding of about $275 million of bonds during the period.

We have announced that we expect to market $100 million of equity securities during 1970, probably towards the end of the year.

Short-term bonds
In the course of 1969, $175 million of first mortgage short-term bonds were sold. In April, $75 million of five-year bonds were issued at an annual cost to the Company of 7.42 percent before expenses. Because of strong demand, the issue was increased from $50 million to $75 million. In July, $100 million of four-year bonds were sold by competitive bidding at an annual cost of 7.73 percent before expenses.

We postponed another $100 million of five-year first mortgage bonds from November, 1969 until early January, 1970 because of what appeared to be an interest rate peak. In the January negotiated sale these bonds had an annual before-expenses cost to Edison of 8.61 percent. Though it cannot be precisely determined, we seem to have saved about half a percent by delaying the issue. If true, this amounts to perhaps $2 million in interest savings over the five-year life of the bonds.

In the '70's, this young man probably will seek his first job. He might eventually become an editor, a skilled craftsman or a computer programmer. Whatever his employment, he and hundreds of thousands like him will need increasing amounts of electricity.

1969 funds statement	(Thousands)
Funds provided by:	
Net income less dividends	$ 33,585
Depreciation and tax deferrals	118,413
Funds provided internally	$151,998
Sales of securities	179,738
Bank loans and commercial paper (net)	86,075
Change in working capital and other items	21,487
Total funds provided	$439,298
Funds applied to:	
Construction expenditures	$396,361
Nuclear fuel expenditures	36,295
Sinking fund debt retirements	6,742
Total funds applied	$439,298

A new bond-buying public
It appears that a new market is developing among smaller investors for these short-term issues. On the two 1969 sales totaling $175 million, about 10 thousand separate holders have been registered with the mortgage trustee. This contrasts with about a third that number registered for $175 million of 30-year, long-term Edison bonds sold during 1968. We are glad to be reaching this mass market of smaller investors.

Other 1969 financing
As we have done in the recent past, we used commercial paper (notes payable) in 1969 to allow ourselves choice in timing debt issues. At December 31, 1969 we had $86 million in commercial paper outstanding.

Commercial paper costs money. Short-term rates have been no cheaper than long-term ones and cut into earnings in the same manner. Our assumption in using short-term bonds, commercial paper and bank loans is that the staggering interest rates now being charged will decline sooner or later, and that we should avoid being locked into long-term obligations at the current high rates.

In the fall of 1969 Edison renewed $60 million in bank loans at the prime rate from Chicago banks, and at December 31 our subsidiary, Mid-Illinois, had $34 million of bank loans outstanding.

During the year we reacquired $11 million principal amount of sinking fund debentures. At year end, our capitalization was 56 percent bonds and debentures, 6 percent convertible preferred stock and 38 percent common stock equity.

12

Food, clothes and exercise are three staples of human life. Electricity helps process coffee cakes at the Kitchens of Sara Lee, show merchandise to its best advantage at Goldblatt's, and light and heat the gym at Hampton Park's all-electric junior high school.

The Midwest's refiner
The Chicago area has struck oil. Northern Illinois within five years may well become the refinery center of the Midwest. Most of the refineries are or will be located southwest of Chicago along the Illinois Waterway. The Union Oil plant at Lemont will use electricity to drive its huge 19 thousand horsepower centrifugal blower. Our salesmen helped to convince Union's management that an electric motor served from our lines is more economic than the steam-driven turbine traditional in oil refineries.

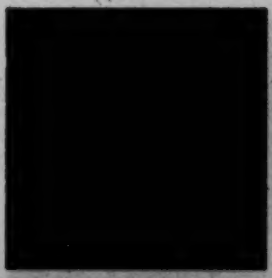
Three other large motors totaling another 20 thousand horsepower also went our way. The new Lemont refinery will be one of the most electrified in the world. It will have a demand of 70 thousand kilowatts and run at 95 percent load factor. Another oil company is now doing site work for a refinery even larger than Union's.

Chemical processors are first cousins to refineries and often locate near them. A number of such plants are in operation or building in our service area. They join a giant, the Northern Petrochemical complex, being developed in three stages over the next several years.

$10 million from giants
Northern Petrochemical and Union Oil, when completed, will contribute close to $10 million to our annual revenues. If fully operative today, these giants would rank third and fourth among our large customers.

Completion of new oil pipelines from Canada and the Gulf Coast to our area coupled with the market advantages of a northern Illinois address have led to this sudden blooming of massive new electrical loads.

An Edison lineman puts his finishing touches on transformers added to serve the expanding power requirements of people. The vitality of our area's commerce and the quality of its goods are shown by pictures of Chicago's Board of Trade and of a gleaming row of electric ranges.



Wages up 6%, benefits higher
As a result of union agreements signed last spring, hourly wage rates increased an average of 6.2 percent. Pensions, insurance and other fringe benefits added the equivalent of another 0.4 percent to payroll. These increases amount to about $12 million on an annual basis. Wages have been renegotiated each year. Fringe benefits, however, had not been negotiated for five years, and the increase in benefits should be looked at in this light.

At December 31, 1969 we had just under 14 thousand employes, an increase of 167 over the same date a year earlier.

181 thousand stockholders
At year end, we had 181 thousand stockholders, down about 2 thousand from a year ago. The slight decrease probably is due to expansion by institutions of their holdings of Edison stock. There were 169 thousand holders of 42 million common shares. In addition, 12 thousand stockholders owned over 4 million shares of our convertible preferred stock.

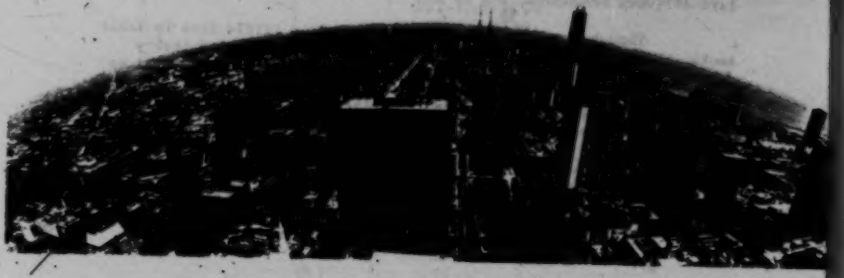
About 120 thousand shares of common were acquired by employes during 1969 under the stock purchase plan, and 43 percent of Edison's employes were in the plan at December 31.

Board and management changes
At the 1969 Annual Meeting last May, Joseph S. Wright was elected a Director of Commonwealth Edison. Mr. Wright is Chairman of the Board of Zenith Radio Corporation. At year end, John L. Gordon, Chairman of the Board of the Central Illinois Electric and Gas Co. Division, retired from active service.

During the year, Wallace B. Behnke, Jr. was elected a Vice-President, Byron Lee, Jr. was named Assistant to the President, George P. Rifakes, was appointed Manager of Fuel, and Charles G. Harnach was promoted to Division Vice-President of our Southern Division.

14

The future of our whole metropolitan world depends upon children such as this. It is Commonwealth Edison's role to furnish clean, reliable, plentiful and economic electric power to him and to eight million others in the '70's.



4428

91

Commonwealth Edison Company

72 WEST ADAMS STREET • CHICAGO, ILLINOIS 60690

January 17, 1969

Dear Security Analyst or Fund Manager:

Each new technology has ushered up its own skeptical and detracting opposition.

The Wright brothers succeeded despite those who pointed out Icarus' fatal plunge to prominence. Battleship admirals scoffed at air power until the Repulse and Prince of Wales went down. Dutch workers tried throwing their shoes - sabots - into newly invented weaving looms and thus were responsible for coining the word sabotage. And one even can imagine manuscript illuminators writing letters of complaint to Gutenberg.

Similar opposition may be gathering against nuclear power, with tales of spiraling capital costs, uranium shortages, atomic bombs, late-delivery brownouts, and so on.

Though the critics are wrong, there's a little fire in their smoke. Take Commonwealth Edison. We have reactor vessel delivery delays. Though no technical problems are involved, Dresden 2 will be eight months late and the two nuclear units following it probably will be several months behind schedule. Despite this, consider the handsome payoff ahead from nuclear power for Commonwealth Edison.

- We have over 5000 Mw of nuclear capacity in six units under construction. We got our four 809 Mw units at an average of $118 a kilowatt. Turnkey contracts, no escalation. Our other two units will cost a third to a half more, depending on how future construction costs go.

- We've contracted for 10 years worth of fuel fabrication at good prices for our six reactors. We've bought all the yellow cake we'll need through 1975, much of it at below $6 a pound.

- By 1974, about half our kilowatthours will be coming from nuclear machines at fuel costs below two mills, including all carrying charges on the fuel inventories. Present system fuel costs average 2.7 mills, and we figure our newest coal-fired units at 2.2 mills.

We could go on and on. Air pollution? We beat the rush two years ago when we volunteered to the City of Chicago to cut SO_2 emissions in half within a few years -- mainly because of nuclear power. Future cost protection? Coal, with a whopping recent eight percent wage settlement, is not going any place but up. But nuclear fuel is mostly a manufactured product, and stands a good chance of price reduction through technological improvement.

We hope you'll understand why we're glad to be the leading nuclear company.

Though medical opinion differs, our experience is that the flu already has passed its peak in Chicago. Why not dodge it and pay us a visit? If you can't make it, give us a call if we can be helpful.

Sincerely,

Preston Kavanagh

POST OFFICE BOX 767 ★ CHICAGO, ILLINOIS 60690

92

December 4, 1969

Dear Security Analyst or Fund Director:

Electric power plants these days are being billed as the worst things since the Krakatoa eruption or Vesuvius' burial of Pompeii. Until a few months ago, Commonwealth Edison had been spared the partly-informed public clamor about pollution which has marked so much of the country. Now, however, things are heating up a bit and we thought you'd like to know our situation.

In summary, we have an early start, some fixing up ahead, and a future program -- thanks mainly to nuclear power -- ranking with the country's best. In detail:

* We're responsible for something over 10% of high level and considerably less of ground level pollution in metropolitan Chicago. Our emissions are mainly sulfur dioxide gas.

* Three years ago we submitted a program to cut coal burn in our six Chicago-area stations in half by 1975. Mayor Daley praised the program as "the first of its kind in the nation" and "an example of what local industry can do".

* A Chicago ordinance effective next July requires that the sulfur content of coal be lowered in progressive steps through 1974. The ordinance allows us to fulfill its objectives by burning less rather than lower sulfur coal. We'll meet that timetable and have applied for the appropriate approval.

* By mid-1973 nuclear plants will be turning out 40% of our kilowatthours.

* Ten years ago we had 58 coal-fired boilers at city stations; today it's 12. We're replacing old peakers with gas turbines, and burning all the gas we can get in the remaining base-load boilers.

* We'll spend $25 million between now and early 1973 for improved or brand new dust collecting precipitators, bag filters, and the like at 11 stations.

* In all, we've earmarked $70 million of our five-year capital budget for pollution control facilities.

* We see no problem in radioactive emissions from nuclear plants. The AEC's standards are stringent, and we shall continue to be well below them. For example, the Jet Set New York analyst making just one round-trip flight to the coast gets more radioactivity than the very closest neighbor of a nuclear plant.

* We're not in hot water on thermal pollution. Lake Michigan is huge and cold, and our lake stations have done and will do it absolutely no damage. For our big new river units man-made cooling lakes are generally necessary.

* We've run ads, developed a squad of personable experts, been on TV and radio, and accepted every speaking date we can arrange to tell our clean air and water story.

* Our billion dollar investment in nuclear (5,200,000 Kw), minemouth (1,200,000 Kw), and gas turbine (1,600,000 Kw) generation is good power system economics. It also advances our clean air cause. These are golden words.

* The Illinois Attorney General intervened in our rate case on the pollution issue. Now the Governor has requested Commerce Commission hearings for <u>all</u> electric and gas utilities to see how the problem can be overcome. This will provide a fairminded and orderly forum to get the facts before our public, and could remove that issue from our rate hearings.

We've been directed (like Isaiah) to write so those who run may read, and thus we blush at three instead of two pages. Explaining pollution, however, is a complex thing and so is doing our full share to throttle it. We hope you'll agree Commonwealth is ahead of its times. And that we are determined -- insofar as we can accomplish it -- that northern Illinois shall have pure water and clean air.

Sincerely,

Preston Kavanagh

NUCLEONICS WEEK — April 4, 1968

COMMONWEALTH EDISON: PROFILE OF NO. 1

BOOTSTRAPPING ITS WAY TO NUCLEAR KNOW-HOW

(First of a series)

Commonwealth Edison takes very matter-of-factly its huge commitment to nuclear energy, the largest of any non-nationalized utility in the world. Some smaller companies may look with awe upon the atom and wonder about its role for them, and the risks lurking therein. Edison views it as just another in the series of technological breakthroughs that have marked the growth of the utility industry—a breakthrough of which the company was ready to take advantage. But let them tell it, as they did in an interview with Nucleonics Week editor Roger Newburger. The Edison cast: J. Harris Ward, chairman and chief executive officer, who alternately joined in at the conference table and sprang up to point to a map or chart on the wall; Gordon R. Corey, chairman of the Finance Committee, and Wallace B. Behnke, Jr., assistant to the president. Most of what follows is in their own words, although edited and reassembled for reasons of space and continuity. For this reason, and because the dialogue was intended to give a picture of the whole company, no attempt is made to identify the speaker of each phrase.

When we made the decision to go nuclear with Dresden-1, back in 1955 (they said), it was mostly due to Willis Gale's farsightedness. He was our chairman then. He felt that this was the most exciting possibility for the next technological breakthrough in the electric-production end of the utility business, and it has turned out to be just that, so far. Nuclear energy offered the solution to several basic problems that we could see on the horizon. Back in the early 1950s, we could see that the logistics of fueling the coal-fired generating capacity needed by 1980 or 1990 would be a problem. We also could see

back then that air pollution, particularly in our metropolitan areas, would be a problem. To us, it appeared that nuclear power might answer such basic, long-term questions. This was well before anyone had a handle on the economics.

In 1951, we were selected by the AEC as one of the four original study teams to explore the possibilities of using the atom for power generation. Our young engineers, along with those of other companies in our research group, worked on it, designed a lot of reactors, worked closely with AEC, fumbled through all those early days while we were learning and getting ourselves tuned up and educated as to what it was all about.

OPTIONS IN CONSTRUCTION MANAGEMENT

Says Commonwealth Edison: Since Westinghouse and General Electric quit the turnkey business, we have found some advantages in having a little more control over construction schedules. But we weren't especially eager for them to get out of it, for turnkey provided another option to us in seeking every possible way of buying the lowest-cost and best unit. . . We're not at all afraid of handling the construction chores ourselves. One key there is knowledge of local labor and we think we have more know-how in this area than GE and Westinghouse—although they have a lot more know-how now than they used to have.

AEC people are sophisticated, conscientious, capable regulators, Commonwealth Edison feels. These are the company's views: They don't do all the things we'd like to have them do, but on some things they listen to us. . . Rather than getting more difficult, it is becoming somewhat easier because we are understanding each other better. These are difficult times for both the regulated and the regulators because of the rapidly changing technology, but we're growing up together in this business. AEC works very

hard at it and we do, too. . . This matter of questions by the ACRS and AEC regulatory staff on the preliminary safety analysis is very time consuming and is one of the big problems power companies have. We try to keep in touch with the letters and questions to other companies through our contacts in the industry and with manufacturers. As time passes, we hope we will be able to solve our joint problems faster and more effectively than we have to date.

Everyone knows when the plutonium glut is going to hit, and it's obvious that this fuel will have to be recycled in water reactors, says Commonwealth Edison. But it also thinks: There is no need to develop for use in 1975 the super-plutonium fuel of 1985. . . The nation can't afford the luxury of redundant research. . . We need some patience and a fairly conservative first-round development effort to get this into the competitive fuel economy. It is important that the independent fuel suppliers have a position here at the earliest practical date but too soon will be too expensive. . . Certainly, they would like to have the utilities pay for all the research and a large portion of the fabrication facilities but we have to worry about cost to the consumer, too. . . Plutonium fuel is not a new subject; only its commercial application is. We must find out what has to be done and who will do it, then get it off to an early competitive start and let the perfect plutonium fuel be developed with the passage of time.

Over and over again, we emphasized to our managers and engineers and accountants our belief in the cost-price-sales-earnings spiral: reductions in costs keep the price of electricity going down; this leads to increased sales, which make it possible to take advantage of economies of scale; this, in turn, brings additional cost reductions and rate reductions and increased earnings. Now, we don't say that we're seers, but because of this

philosophy we're anxious to take advantage of every new wrinkle that comes along.

When it came to Dresden-2, we saw the advantages from an air-pollution standpoint, but we were particularly pleased—and just at first a little surprised—when we saw nuclear prices coming into the ball park where they could beat even our new fossil-fuel plants supplied by unit trains. Just one year before we ordered Dresden-2, in February of '65, we had put into operation the largest unit train in the world, and it was going to cut the price of bringing coal from southern Illinois to Chicago from $2.56/ton to $1.30/ton. We thought this was a terrific breakthrough for coal, but then we saw Dresden-2 coming in still cheaper. Once we had made the decision to go nuclear there, Dresden-3 and Quad Cities and the Zion units followed along naturally. Then we saw more and more the potential advantages in the air-pollution field and the possibility, as metropolitan siting becomes acceptable, of getting our stations closer to load centers, thus helping alleviate—both in cost and appearance—the problem of cross-country transmission lines.

(In 1973), when Zion-2 is scheduled to begin operating, about 50% of Edison's output will be nuclear-generated. Is the company worried about such a vast commitment to the new technology, with plants of an untested size?)

We think the possibility of nuclear power stations not working is almost non-existent. The technology is well proven. Certainly we have worries about getting them built on time and keeping them running, but we have these with every plant. For instance, when our Ridgeland-1 was built it introduced a certain kind of stainless-steel piping which was a great advance back in 1951. Soon after it went into operation, cracks developed in the stainless steel. We had to tear out sections of it and had all kinds of examinations made of the piping. We never have gone back to stainless of that particular kind. For another thing, apparently nobody yet knows how to build a boiler tube, they're always springing leaks, and boiler availability is our biggest problem with our modern coal-

fired units. These boilers are 22 stories high, and when you develop a pin-hole leak in one you shut the whole thing down and, after an eight-hour cool-off, you send up a man in an asbestos suit in a bo'sun's chair to fix it. It's a perpetual problem. Maybe there's a little more risk with nuclear hardware, but we've been making and using turbines and condensate pumps and fans for years and they're certainly not new parts. Even though we haven't been making reactors for years, we did start studying them in 1951. Four years later, we ordered Dresden-1 for service in 1960. Then we played with Dresden-1 for almost five years before ordering Dresden-2. So you see, the idea of a reactor is not very new.

Then, as you get into the 1970s, you'll see an increase in regional interconnections between large power systems and a decrease in the number of weak spots in these systems. And you'll know where the weak spots are, the difficulties with them. Sometimes you'll have to build a line and sometimes you'll have to persuade the other man to build a line. Now, when we put a nuclear station out there at Quad Cities, we establish a joint-ownership relationship with the utility to the west and we are all part of the 345-kv loop around the Middle West. If we have trouble with the plant, various interconnected companies will make up the lost capacity. So, as you increase in strength and interconnections, the vulnerability of any single system to the loss of an individual plant becomes a matter of less concern.

These 1,000-Mwe plants are not so strange, anyway. They're a little bigger, but not very much bigger even in terms of physical dimensions. Go back to Dresden-1 and its 200 Mwe. What was the Vallocitos Boiling Water Reactor? 5 Mwe? There was an extrapolation of about 20 to 1, and we made it all right. This has been true all the way through the power business. Not so long ago, we were building 150-Mwe fossil units, then moved to 300s, then 600s. It's a matter of degree. And General Electric and Westinghouse are competent designers and manufacturers, and they have a lot riding on these machines, too.

NEXT WEEK: Limitations on mine-mouth plants; future siting; thermal effects.

NUCLEONICS WEEK—April 11, 1963

COMMONWEALTH EDISON: PROFILE OF NO. 1

NUCLEAR COSTS ARE RISING, BUT THERE'S NO CEILING ON COAL, EITHER

(Second of a series)

Like other utilities, Commonwealth Edison maintains a running comparison of nuclear and fossil-fueled power-production costs. In recent years, Edison's comparisons have led to the Dresden, Quad Cities and Zion nuclear units. Despite recent sharp price rises for nuclear-plant components, the company sees little coal in its future. Three executives tell why in an interview with NUCLEONICS WEEK *.

Sometimes (they said) we have to remind people that Dresden-1 was ordered in 1955 and went into service in '60; it's been running a little over seven years but the first full equilibrium core loading of fuel won't be burned up until sometime in the early '70s. We have our estimates, of course, but there are a lot of imponderables in trying to compare costs, particularly when it comes to estimates of future escalation. We think the construction costs of nuclear plants are going to be affected by escalation of construction labor and things like that; Zion won't go into service until 1972 and '73 and we won't know until it gets built how much that escalation has amounted to. In addition, future fuel costs are an equally important factor because they will total more than the plant cost over the life of the unit. But, despite escalating

[Pictures]

* The three executives are J. Harris Ward, Commonwealth Edison chairman; Gordon R. Corey, chairman of the Finance Committee, and Wallace B. Behnke Jr., assistant to the president. They discussed the company's philosophy and management techniques with NUCLEONICS WEEK assistant editor Roger Newburger. This second of a three-part series again is mostly in their own words and, so as not to interrupt the flow, identification of the specific speaker is omitted.

plant costs, we feel that escalation of coal costs over the life of a competing coal-fired plant would be at least as great as it will be for nuclear fuel. That could be 35 years—say 1973-2008—and who can say what the price of mining coal in Illinois is going to be in the year 2008?

You cannot buy coal now for such a plant without buying it on virtually a cost-plus basis. Our policy is to buy it on 5-10 year contracts. Coal is not a great big capital investment business; about all you do when you buy it is pay what it costs a man to get it out of the ground. We believe we can do better buying it, not from year to year, but in 5- or 10-year intervals. That way, we can buy from the most efficient miners—the ones who have the best people and are doing the best job at any given time. If we were to pick out one company and say; "We are going to give you a long contract," obviously he'll retort, "Well, I'll give you the best price I can, but I have to have escalation," and then you end up with cost-plus.

Partly as a result of air pollution, partly because of urban congestion, there has been a trend to mine-mouth generating stations. We put one in, too—the first unit went into service last May. A few years ago, we couldn't have done this, but then 345-kv technology came along. We needed additional tie lines to the south for the expanding interconnections and we had to put at least one of those lines through the mine area anyway. When we gave the mine-mouth the benefit of this transmission in figuring costs we were able to prove it in economically, so we thought we might as well use the line as an equivalent to shipping coal from central Illinois to Chicago. Probably similar situations have brought about the mine-mouth plants in the East. The expanding transmission grid made lines available anyway and you didn't have to figure that as part of the station cost.

But once you get a mine-mouth plant, you absolutely have to contract for coal to supply it. The capital cost on the plant is $120-million, but the capital cost on the mine is about $10-million. Obviously, you can't be put in a position where the $10-million investor can hold you up because you have your big $120-million plant

sitting beside his mine; so, for all practical purposes, you have to buy the mine. That is the situation with out mine-mouth plant: we made a long-term cost-plus contract for the coal, it runs to 1982 with three 10-year renewal options that will take up to the year 2012. The need to protect your investment in a mine-mouth plant may give a false impression that longer-term coal contracts result from the competition with nuclear fuel.

Of course, on any coal-fired plant we are concerned about air-pollution, just as we are concerned about thermal effects on cooling water of both our nuclear and fossil plants. Neither of these ideas is exactly new around here; we've been thinking about them for some time, and we try to plan to avoid problems. We're fortunate in the availability of water in our 11,000-square-mile service area and we try to be foresighted about our use of that water.

We're not yet hurting for sites for future plants: we have several more river locations available and Lake Michigan provides a vast amount of water. In theory, if it weren't for transmission problems, we could expand lake-front stations, such as Zion, indefinitely, subject of course to environmental effects. But the metropolitan area is so built up, especially with heavy industry, that we can't put through too many transmission lines. While we can take a million kw on our line from the East—maybe even a little bit more—we're limited by the risk that one airplane or one tornado conceivably could knock out both these circuits. When you have a big generating station you like to have at least two ways of moving the electricity, and you prefer to move it at pretty high voltages. That's very hard to do through the center of a town because of the electrical losses inherent in going underground with a 345-kv line. The cost is prohibitive, too.

ON FUEL DIGGING AND DESIGNING

Commonwealth Edison says: We have been thinking for six or seven years of the possibility of getting into uranium exploration. We probably shouldn't be in it unless others are not

doing the job right. . . We had feared some shortage of uranium in the early 1970s but the situation seems to have eased. We have committed for over $100 million worth of yellowcake at good prices and we're not nervous about our supplies. . . We're not interested in leasing fuel. We can get money as cheaply as anyone else and we're inclined to do our own financing. . . We lean in the direction of providing our own fuel design; we want to understand the fuel world completely. Also, we fully expect to manage our own nuclear fuel while it's in the reactor, rather than what we do now, on the services of the fuel suppliers.

There are advantages to everyone in having plants reasonably close to load centers but we're not pushing this too hard. Dresden is not too far from Joliet, but that's not the same as being near the Oranges or Newark, in New Jersey; it's a relatively isolated spot. The plant was quite well received, too. After all; Chicago was the birthplace of nuclear power, and Argonne National Lab, where the boiling water reactor was conceived, is not far from Joliet. It was only logical that our first nuclear plant should be built nearby. Moreover, with the property taxes that we pay on Dresden, the community was able to fix up its schools and make other needed improvements. The people were genuinely happy to welcome Dresden station.

When time came for another station the people of Zion were inclined to take it for granted that it would be located there on land we had owned for over 10 years. When word leaked out that we were considering a demonstrate site near Seneca, Zion got pretty upset, thinking about all that tax money with which it could build schools and parks and other things a community likes to have. And the people in Seneca began to think about it, too: that maybe it would be a lot better than having a fossil-fuel plant or an industry throwing out a lot of smoke. They wound up with a spirit of competition, all on the positive side. No one in this area

has picked up any of the negative feeling that existed elsewhere in the country. There are some conservationists here concerned right now with preservation of the natural prairie that we have in Illinois, but there is no conflict with Dresden and we believe our relationship with them is friendly.

There's been a lot of talk about building an airport for Chicago about five miles out on Lake Michigan and, if they ever did it, perhaps it might make a good deal of sense for us to have a generating plant there, too. But this is still pretty much in the realm of conjecture. We have no problem of overheating lake water, since we will be well within the temperature limits, and even on the inland streams we haven't had to go to cooling towers for any of our plants. We've tried to plan very carefully to build them far enough apart to give river water adequate time to cool between plants so we can stay within the regulations. We still have a number of potential sites and room for added capacity at existing stations. We may have to go to cooling towers some day, but not yet.

We think, also, that technology is helping, not hurting us. We're building 1,000-Mwe nuclear stations that will heat the water to a certain temperature. Hopefully, 30 years from now, they will be replaced by 2,000-Mwe stations that won't heat the water any more than the 1,000-Mwe stations did. This happened in the coal side of the business and it's bound to happen in the nuclear side, too. We moved to higher and higher steam temperatures in the coal-fired boilers and yet maintained the same temperature in the condenser. Right now, the low cost of nuclear fuel doesn't lend itself economically to the use of plants with high steam temperatures and pressures and correspondingly more efficient turbines. Steam superheat, for instance, just disappeared because, economically, it didn't have a place. But we're speculating that this may no longer be true with the advanced breeder technology that we'll have in the 1980s.

NEXT WEEK: It's no business for midgets; joint ventures; personnel development.

NUCLEONICS WEEK — April 18, 1968

COMMONWEALTH EDISON: PROFILE OF NO. 1

NUCLEAR POWER IS NOT A SMALL-COMPANY BUSINESS

(Third of a series)

Commonwealth Edison is a giant and it minces no words in stating its feeling that this benefits the public. The power-generation business is not meant for midgets, said three executives in an interview with NUCLEONICS WEEK *.

Edison is now the single descendant of well over 200 power companies, but back in 1938 the various consolidations to that time had resulted in five separate companies (the three executives explained). It was about that time that the five began to be operated as a single system, thus permitting better over-all planning. When an area is covered by many small companies you'll have one company planning to put a plant here, another company thinking of a new unit there, with resultant lack of cohesion. In New England, for instance, the companies have gotten together now but, although they were thinking 15-20 years ago about this kind of over-all planning, the will to achieve it had to overcome normal inertia and this cost them a great deal of time. Some might think this kind of talk sounds monopolistic, but we think it's for the good of the public.

What happens to the little companies in this day of big nuclear plants? We're not sure that there is a single

[Pictures]

---

* The three executives are J. Harris Ward, Commonwealth Edison chairman; Gordon R. Corey, chairman of the Finance Committee, and Wallace B. Behnke Jr., assistant to the president. They discussed the company's philosophy and management techniques with NUCLEONICS WEEK assistant editor Roger Newburger. This last of a three-part series again is mostly in their own words and, so as not to interrupt the flow, identification of the specific speaker is omitted.

solution for every situation. We had such a problem in our territory a little over a year ago. Rockford, the second largest city in Illinois, was virtually surrounded by our system—an island in our service area served by Central Illinois Electric & Gas—and that company opened discussions with us on power supply and nuclear units. We both recognized the solution, and a merger that would best serve the interest of both companies' customers and stockholders was relatively easily accomplished.

There are other situations and other solutions. In our territory, there are seven municipalities with their own power distribution departments. Two generate their own electricity. We supply the others at wholesale rates which are under the jurisdiction of the Illinois Commerce Commission and the Federal Power Commission. We think the regulatory commissions are perfectly capable of looking after the well-being of these municipalities. After all, each of these towns that we serve is a smaller user of electricity than some of our large industrial customers; no one hears any of the industrial customers asking for a share of one of our nuclear plants and we seek no justification for a municipality to seek such a share, or a voice in running the plant, either.

The industry may seem to be evolving in a direction which favors one kind of company more than another, but we think it desirable to have utility systems large enough to take advantage of the economies of size made available by today's technology. This means large enough—on the order of 10,000 Mwe—to buy and use a 1,000-Mwe unit. Maybe tomorrow will bring some other technological development which will indicate a different size of system. Two things, though, seem quite clear: little generators are a very expensive luxury, and atomization of the industry, so as to give every little company a chance to own a small piece of a reactor, would create a difficult situation. We can just imagine a nuclear plant with some people having a 1% ownership and a 1% vote and somebody else having a 3% share and a 3% vote, and every time you wanted to buy some yellowcake you'd get all the voters together to see if they could agree on the purchase.

The writing a few years ago of the National Power Survey demonstrated that public and private power people can work together. One of us was involved in that, along with a man from TVA and the FPC staff. We found that philosophically, as far as operations and objectives were concerned, we were not far apart. It seems unfortunate, therefore, to reinject this old question of public power vs. private power into the matter of nuclear plants. TVA is building power stations and distributing power and selling it to municipalities, and their municipal customers aren't saying, "Please give us a piece of Browns Ferry."

Municipal systems should be given the benefits of large-scale economies, but they can have these by becoming customers of the big systems. It is not a small-company business. Perhaps some would say that this is against America's basic philosophy and that anyone should be able to take a crack at anything. But that's like saying anybody can get into the automobile business. It just isn't true. This country has passed the point where you can economically build a car in your barn. Small systems will continue to operate and small plants may occasionally be competitive because of geographic isolation or special tax or governing-financing privileges, but in any wider view construction of small generating units seems wasteful. There are advantages in being small, but bringing uneconomic generating units on line is certainly not one of them.

ON BREEDERS AND CONVERTERS

The r-&-d effort on fast breeders is proceeding at an adequate pace, Commonwealth Edison thinks. It explains: U.S. timing may lag a little behind England's but we have different economic concepts and different objectives. They don't look upon capital costs the way we do and they have an obvious interest in minimizing their dependence upon uranium supplies from the outside world. . . Our breeder studies with General Electric and Westinghouse should bring

us in two years to the point of decision on building a demonstration plant, then about five years more for construction and operation. If the breeder comes in on this schedule, there probably would be no room for the advanced converter, especially if light-water reactors continue to improve. However, we don't rule out the possibility of the converter and we continue to watch all these technologies.

Collective plant ownership is a possibility, but the partners should not be too different in size. When we negotiated the Quad Cities agreement with our neighbor, Iowa-Illinois G&E, it was arranged that we would manage it for the good of both parties. This was a fairly simple approach, but even this partnership can never be quite as efficient as single ownership. For instance, if yellowcake is purchased at various times and prices for both Quad Cities and other Edison plants, what is the price to be charged to Iowa-Illinois? Only goodwill and mutual trust between us have enabled us to solve such problems. Our management of Quad Cities does not relieve us of any legal liability to be fair; in fact, it puts the monkey on our back. But at least there is no committee management, which we believe is ineffective, inefficient and cumbersome.

Our management philosophy is toward decentralization. We are split into seven geographical divisions, each with a vice president who, in effect, is running his own sizable utility company. Some of these divisions have $100-120-million a year volume and 400-500,000 customers. We move people around among divisions, make them profit-conscious, cost-conscious. We show them what other divisions are doing. Since we have adopted this approach, all the divisions have improved in performance. This is what competition does.

Another effect of competition is that it encourages young men to want and accept responsibility. Some of our divisional vice presidents now are under 40 years of age. Our structure lends itself to similar treatment of other personnel. We can and do move bright young

engineers into the nuclear field, bright financial people into nuclear purchasing and nuclear analysis. We're constantly training and developing our people, sending them off to school, to national labs, to Dresden station, to Purdue University for the fuel-management course we've helped sponsor. When we hire we're interested in a man's study discipline, but not exclusively.

When we first got into nuclear matters we started with just a few young electrical and mechanical engineers, a chemist, an accountant. Cliff Zitek was a chemist; we got him into Argonne National Lab for training in the early days. We had Murray Joslin then, and the late Titus LeClair, both electrical engineers, and they set about learning the business. You need only a few highly competent people with specialized disciplines who can help you with some of your thinking and development.

The Dresden station has been our keystone: the young engineers worked along on its development, put it into service and operated it. We have worked hard to put as many people through that station as we could so that today we have a fairly sizable and extremely capable staff with a wealth of experience. A lot of these young men who started at Dresden have gone on to become supervisors and managers in our engineering area. The fellow who buys our nuclear fuel trained at Dresden; so did another man, who then worked in our engineering department, designed for awhile and now is stationed at Westinghouse studying fast-breeder technology. We have another engineer at General Electric in breeder work, and there's one at the National Reactor Testing Station, working on EBR-2. We will bootstrap our way to the fast breeder just as we did in light-water reactors. You don't have to start with a whole platoon of specialists in each discipline. Our people are learning the language and the technology. They may not have their hands on all the subjects yet, but they'll be educated by the time we'll have to decide if we want to build a breeder.

We would like to see universities turning out more nuclear specialists; an education in nuclear engineering is important to power companies. But specialized formal education isn't the whole story. Put a man at the Dresden

station for six years and he soaks up an amazing amount of knowledge. He may not design the first fast breeder, but he'll certainly know how to operate a boiling water reactor. This is technical work of a repetitive nature, and it represents good jobs which don't need to be filled with graduate engineers or physicists. You look back 10 or 20 years and we had engineers doing a lot of things then that technicians do today. The important thing—for both technicians and management people—is to give them the opportunity and incentive for development. We think we offer as much of these as anyone in the business.

* * *

Do saxophones sound better in all-electric schools? We think so. These students at Hampton Park's West View Junior High School seem to like their environment. Education is a fast growing part of the nation's economy, and because of northern Illinois' high income and education levels, new school construction is especially strong in our area. We have taken advantage of this by promoting over three million square feet of all-electric schoolroom space.

and other operations. Of the electric payroll, 72.5 percent was charged to operating expenses.

Depreciation on electric plant in 1968 was $94,020,351, equaling 3.30 percent of depreciable property. This was up slightly from 3.29 percent for 1967. Commonwealth Edison uses one of the highest depreciation rates in the electric power industry. Technological change is rapid, and we take advantage of this by purchasing the most modern machines and equipment. Also, we think it prudent to make adequate provision now for possible future obsolescence.

Taxes Up Over Eight Percent

In 1968 we provided $202,310,655 of local, state and federal taxes for our electric operations. This is equal to $81 for every customer on our lines. This year we provided 8.6 percent more for taxes than in 1967, and state and local taxes once again had the largest portion of the increase. We try to manage the affairs of the Company to maximize operating economies and then to pass these savings along to our customers and stockholders. Rising costs and especially rising tax costs are major offsets to the economies we are able to achieve.

Our electric tax provisions were:

	1968	1967	Percent Increase
State and local taxes	$101,287,392	$ 90,982,961	11.3
Federal income taxes	85,640,000	83,009,000	3.2
Deferred federal income taxes (net)	11,947,108	9,302,000	28.4
Social security and miscellaneous federal taxes	3,436,155	2,957,374	16.2
	$202,310,655	$186,251,335	8.6

Record Summer Load

A record peak load of 8,950,000 kilowatts was set between 1 and 2 p.m. on August 23, a hot, humid Friday afternoon. This is 1,307,000 kilowatts or a remarkable 17-percent higher than 1967's summer peak. While 1968 had normally warm summer temperatures, the prior year was one of the coolest in 50 years. In effect, 1968's peak reflected the heat sensitive load growth of almost two years.

Interconnections

Reliability of our service is enhanced by the Midwest's network of high voltage interconnections. In May, tornadoes destroyed or damaged 84 towers on two different 345,000 volt lines, spaced four miles apart, and leading from our Kincaid Station. Because of our interconnections, there was no interruption of service to our customers.

New Generating Units

In June, a 600,000 kilowatt twin to the unit brought on line in 1967 was placed in service at our Kincaid Station. The two-unit plant in central Illinois is located virtually on top of the country's largest deep coal mine. Instead of bringing coal to the generating plant, the generating plant has been brought to the coal. Though Kincaid Station is far from any urban area, $6,000,000 has been spent at the plant for air pollution control facilities.

During 1968 we ordered a coal-fired unit to be located at our existing Powerton Station near Pekin, Illinois. It will have a capacity of 840,000 kilowatts and is scheduled for completion in the spring of 1972.

We decided on the Powerton addition because of the strong growth of our peak loads and because coal-fired units can be built more rapidly than nuclear units. While

* * *

Farmer John Moran dries corn on a 500 acre all-electric grain farm near Manteno. He estimates his drying expense at under 4¢ a bushel using electrically driven fans and duct heaters, about half the operating cost of his former system. Mr. Moran, chosen in 1967 as Illinois' Outstanding Grain Producer, will use a total of about 130,000 kilowatthours this year. We serve seven million farm acres in a territory containing some of the Midwest's richest soil.

this decision was taken primarily because of accelerating load growth, it also will give us protection against delays in delivery of our nuclear units.

Dresden 1, a 200,000 kilowatt nuclear unit, has been running well since it came on our system in 1960. In addition, we have six more nuclear units under construction.

Dresden 2, the first of the six, is an 809,000 kilowatt nuclear generating unit being built under turnkey contract by the General Electric Company. While the unit should begin producing kilowatthours in the fall of 1969, full commercial operation is not expected until the turn of the year. When we ordered the machine four years ago, we planned to have it ready for the 1969 summer peak.

The delay has been due to start-up problems in a subcontractor's plant built to fabricate reactor vessels. The reactor vessel makes up only about five percent of the total cost of a nuclear unit, but its timely delivery to the construction site is essential to on-schedule completion of the unit. Though the reactor vessel fabrication bottleneck appears on its way to being broken, we still expect delays of several months for the next two nuclear units coming on line after Dresden 2.

Nuclear Savings

Despite these delays, we are glad to be the nation's leading nuclear power company. This leadership has enabled us to assemble and retain an outstanding staff of young nuclear scientists and engineers. Also, because we were early in the field, we were able to buy nuclear fuel and generating units at low prices with limited exposure to escalation.

Four of our six nuclear units on order were purchased on firm price, turnkey contracts for an average of $118 per kilowatt, including all overheads. The two others, at our Zion Station, are expected to cost a third to a half more, depending on future construction costs. In all, these six nuclear units have a total capacity of over 5,000,000 kilowatts at prices which look more and more attractive in the light of today's market.

In addition to providing low cost capacity, our nuclear units will be powered with economical fuel for which contracts already have been signed. We have purchased ten years worth of fuel with a very limited exposure to price escalation. All in all, we estimate that by 1974 our nuclear units will be saving us $10 million a year in capital and operating costs, compared with coal-fired units of the same vintage.

Capacity Growth

On order for 1969 and 1970 delivery are 727,000 kilowatts of fast-start peaking units. These will join the 664,000 kilowatts of similar capacity installed during 1968. These machines have low capital costs—about $90 per kilowatt—but relatively high fuel costs. They can be built quickly and because they require no cooling water, the units can be located near our load centers, thus cutting transmission investment.

We shall depend upon our big nuclear and coal-fired units to meet our base loads, using the peaking units for a relatively small number of hours each year to meet seasonal peaks and unexpected outages in the larger units. Because the turbines are small and can be started quickly, they can be brought on line in small increments as our load rises.

Capacity additions are carefully planned to serve the rapid load growth in our service area. An illustration of the strength of this growth is that five years ago we had 6,762,000 kilowatts of net generating capability. Today that figure is 9,757,000. And five years hence, after new units have been added and older equipment retired, our net generating capability will total about 15,800,000 kilowatts.

Edison seeks A-site Downstate

By Harlan Draeger

Commonwealth Edison Co. said Tuesday that it is seeking options on about 7,000 acres of land in La Salle County as a possible site for a nuclear power plant.

The land is located near Seneca, 80 miles southwest of Chicago's Loop and not far from the company's Dresden nuclear plant.

"We have no commitment to build anything out there," an Edison spokesman said. "We do have agents trying to obtain options."

HE SAID present expansion plans are expected to meet generating needs through 1975.

"We will need additional capacity in 1976," the spokesman said, "but where or what it will be has not been determined. It is a possibility that there could be a plant in this general vicinity."

The spokesman said that, if a plant is built near Seneca, it is likely to be a nuclear generating station. "We're fairly well committed to a nuclear future," he said.

FIRST REPORTS that Edison was trying to line up land options near Seneca came from real estate agents in La Salle County.

Edison officials said that any big new plant would require water cooling facilities, probably a pond.

COMMONWEALTH Edison opened its Dresden nuclear power station near Morris in 1960. The second Dresden unit now is being tested for a start-up this spring. A third unit will go into operation next year.

Two nuclear units also are being opened at Zion and in the Quad Cities area.

By 1973, the company expects to be generating about 40 per cent of its power with nuclear facilities.

Nuclear power for Chicago: our first unit works so well we're building you five more.

DEFENDANT'S EXHIBIT 96

Dresden One was our pioneer. Sure, it helped make a brighter Chicago. More important, it showed that nuclear-powered generating units are more efficient and reliable. And, by using nuclear energy we could produce electricity at about ten percent less cost.

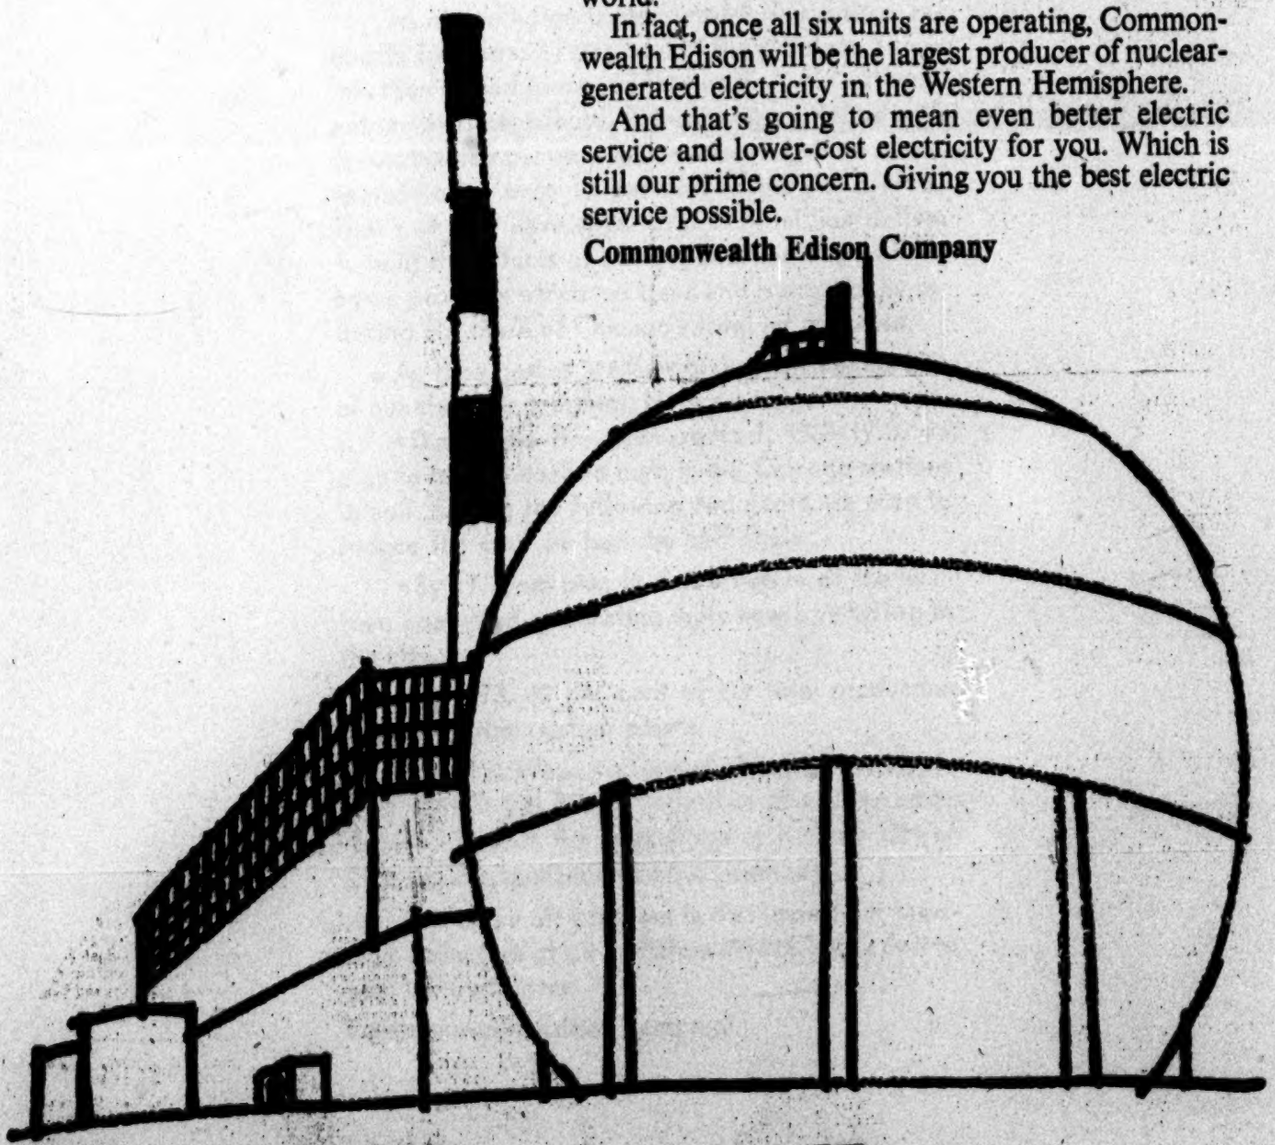
Result?

By the early 1970s we plan to add five more nuclear units. Each to be one of the largest in the world.

In fact, once all six units are operating, Commonwealth Edison will be the largest producer of nuclear-generated electricity in the Western Hemisphere.

And that's going to mean even better electric service and lower-cost electricity for you. Which is still our prime concern. Giving you the best electric service possible.

Commonwealth Edison Company



The bright new ideas are Electric.

DEFENDANT'S EXHIBIT 97

Commonwealth Edison Reports on Chicago's Air Pollution Problem

We share the concern of all Chicagoans for clean air. Edison's future depends on Chicago, just as Chicago depends on Edison for electricity.

As air pollution is measured today, Edison accounts for under 11 per cent of the problem. This is less than it used to be and far less than, for instance, automobiles contribute. But we're not satisfied with favorable comparisons and we don't want to be responsible for even 11 per cent of the pollution. That's why we have spent over fifty million dollars to limit the effects of burning coal and why we have had a program which has been and is drastically reducing our share of Chicago's total air pollution.

As time passes, we'll be giving you the features of our clean air program. Here's a start:

- During the five-year period, 1968-1973, we plan to cut the coal we burn in our Chicago stations in half. During the following two years, we plan to reduce the coal we burn by half again.
- By 1973, we plan to retire twelve of the nineteen coal-fired generating units now operating in the city.
- By 1973, 40 per cent of our total production will come from nuclear plants.
- We'll continue to be well ahead of the objectives established for the reduction of sulfur emissions set forth in the original schedule of the City of Chicago's air pollution control ordinance.

Our clean air program is designed for maximum reduction of air pollution at reasonable cost to you, our customers.

DEFENDANT'S EXHIBIT 98

Commonwealth Edison Reports on Progress Toward Cleaner Air

In January 1967, Commonwealth Edison Company submitted a report to the City of Chicago outlining plans for an accelerated program of air pollution reduction consistent with maintaining power reliability throughout the Chicago area. We promised to do our share to clean up the air while continuing to meet our important responsibility of providing power whenever and wherever it's needed throughout our 13,000-square-mile service area. Here's how we're living up to our responsibilities:

We're burning less coal

The fastest way we can cut down our share of Chicago's air pollution is to burn less coal. We're following this plan and meeting our targets ahead of schedule. In 1968 we cut the coal-burn at our four Chicago stations by nearly 15 percent. By 1973 we'll be burning 50 percent less coal in Chicago than we did in 1967. This means there will be half the smoke coming out of our stacks—half the sulfur dioxide, half of all emissions. And by 1975, we'll cut our coal-burn in half again.

More furnace retirements

Since 1956, we have retired 14 coal-fired units from our four Chicago plants. Twelve more units will be retired in the near future. By the end of 1971 only seven will be in operation. The coal-burning units are being replaced by fast-start peaking units that use gas or low sulfur oil, by extra-high-voltage power lines that bring power into Chicago from distant generating stations, and by clean nuclear energy.

Use of natural gas increased

Our generating stations are using natural gas in greater quantities. This year, gas burned at our plants in and near the city will replace nearly 1,700,000 tons of coal. A great deal of this gas, along with low sulfur oil, is fueling the fast start-up generators we've installed in our plants during the past two years. It cost $110 million to install these units. They will help solve the air pollution problem, while improving the dependability of our power supply.

More nuclear power

Clean, combustion-free production of electricity is a specialty of nuclear power plants. Dresden, our first nuclear station, has produced over 8¼ billion kilowatt-hours of electricity for our customers since it went into operation in 1960. Now we're spending $900 million for six additional nuclear units and fuel to raise our nuclear capacity above 5 million kilowatts by the end of 1973. In that year, nuclear generation will account for 40 percent of the electricity required by our customers.

These are the main points of our clean air program. In the near future, we'll be telling you about additional aspects. We hope you'll agree that we are doing our share to give Chicago clean air.

DEFENDANT'S EXHIBIT 99

A Public Service Memorandum from Commonwealth Edison

No smoke. No dirt. No fumes.

Dresden Number One
The world's first privately-financed commercial plant for nuclear production of electricity. It is located on a 950-acre site near Morris, Illinois, where the Des Plaines and Kankakee Rivers join to form the Illinois River. Dresden was owned by Commonwealth Edison in June, 1959, and has operated successfully ever since.

In the foreground and underneath, the channels for a new nuclear power station, Dresden Number Two, which will open this Spring.

How Commonwealth Edison pioneered the production of electricity from a vast new source of energy which does not pollute the air you breathe

It all began on an abandoned squash court under the stands of Stagg Field at the University of Chicago.

There, on December 2, 1942, a team of scientists under the direction of Dr. Enrico Fermi achieved the first nuclear chain reaction. It was the power of the universe brought under man's control.

A new age began that day. Mankind had discovered how to use a new source of energy, with limits not yet known, to augment the non-renewable supplies of coal, oil, and natural gas buried in the earth millions of years ago and being used up at an enormously increasing rate.

For nuclear power comes from the heart of the atom. It can be made into useful energy anywhere that a nuclear reactor can be built and operated. Unlike the burning of coal, oil, and gas, nuclear reactions produce no smoke, no dirt, no fumes to pollute the air.

Shut the Pottery Plant, at Dresden

Clean, silent nuclear energy can be transformed into clean, silent electricity, at costs which permit its use in most parts of the United States today; eventually, everywhere.

The first electric generating plant was that of Thomas A. Edison. In 1882 this plant, located in New York City and powered by a coal-fired steam engine, began generating electricity for 800 incandescent light bulbs in the factories, offices, and homes of a few customers.

From that time on, as new uses for electricity were found and the demand for it increased, power had been supplied by the burning of coal, oil, or gas, or by water power.

Although Dr. Fermi may not have thought of his achievement in those terms, it was as though thousands of Niagaras, Hoover Dams, and Grand Coulees suddenly had been put down on the face of the earth.

Again it was in the Chicago area that the commercial use of privately-financed nuclear energy first became a reality: at Commonwealth Edison's 200,000-kilowatt Dresden Nuclear Power Station, 50 miles southwest of Chicago.

It was designed and constructed under the close supervision of the Atomic Energy Commission which, on May 4, 1956, issued a construction permit.

Dresden went on full power June 29, 1960.

Since then, 13 other nuclear plants have been put into operation by other electrical companies in this country. But Commonwealth Edison, the pioneer, remains the leader. Our nuclear program is the largest of any private utility in the United States, both in terms of dollars invested and kilowatts of capacity.

From the time a company decides to build a nuclear plant until the plant begins to produce electricity, at least five years pass. That's if all the contractors meet their delivery dates. It's safer to plan on seven years.

Pollution-Preventing Pellets

Inside the nuclear reactor at Dresden are fuel rods filled with pellets of nuclear fuel—one ounce each pellet is the energy equivalent to a ton of coal that can't burn to ashes, dirt, or fumes.

We now have six new, large, nuclear generating stations under construction.

Dresden Number Two will be in operation this Spring.

Dresden Number Three is scheduled to go on line next Winter.

Each of these new Dresden units has more than four times the capacity of Dresden Number One.

Yet this is only one long stride in our nuclear program.

Four more nuclear units are being built.

Quad-Cities, on the Mississippi River near Rock Island, Illinois, will have two units like the new ones at Dresden. The first is scheduled to open in 1971, the second in 1972.

At Zion, Illinois, on Lake Michigan a few miles south of the Wisconsin state line, our sixth and seventh nuclear units are under construction. One will open in 1972, the other in 1973.

Well within the next four years, our total capacity of the nuclear stations will be 5,200,000 kilowatts, 26 times what it is today. That is far more electricity than the entire city of Chicago now uses.

By that time, Commonwealth Edison will have spent nearly one billion dollars to develop nuclear power, to keep pace with your growing demand for electricity without emitting the slightest trace of smoke, sulfur dioxide, or dust.

We have spent and are spending millions more for the most modern dust-collecting precipitators, for gas turbines, and for the conversion of coal-burning units to other fuels.

Commonwealth Edison's total activities to reduce and prevent air pollution add up to the greatest single effort to clear the air which we know of today.

Commonwealth Edison Company

A Public Service Memorandum from Commonwealth Edison

You're looking at 20,000 tons of smokeless, fumeless "coal."

This is a picture of a nuclear fuel "bundle."

It's 14 feet long, 5½ inches square.

It holds 49 fuel rods, each made up of pellets of nuclear fuel so small (and so safe) you could hold a dozen or more in your hand.

It will produce as much electricity as 20,000 tons of coal, without putting the slightest trace of smoke or sulfur dioxide into the air.

In a month or so, it will be making power for you at Commonwealth Edison's new nuclear power unit, Dresden Number Two, 50 miles southwest of Chicago.

Since June, 1960, we have operated the world's first privately-financed nuclear power station, Dresden Number One, designed and constructed under the close supervision of the Atomic Energy Commission.

Scientists from the U.S. Public Health Service recently made a complete review of Dresden One and its effect on its surroundings. They checked air, rain, snow, soil, corn, grass, milk, cattle, fish, and river water. They found no harmful effects, after ten years of operation.

Commonwealth Edison has the largest program of any electric company in the nation for the production of nuclear power.

Inside this "containment vessel" is the nuclear reactor for Commonwealth Edison's third smoke-free, fume-free power station: Dresden Number Three, scheduled to go on line next winter. The protruding pipes will carry steam to and from the vessel's interior, as in the first two Dresden nuclear power plants now in operation. Edison's nuclear stations will clean, air and water

We have five more new, large, nuclear generating units under construction.

Dresden Number Three is scheduled to go on line next winter.

Quad-Cities, on the Mississippi River near Cordova, Illinois, will have two units. The first is scheduled to open in 1971, the second in 1972.

At Zion, Illinois, on Lake Michigan a few miles south of the Wisconsin state line, our sixth and seventh nuclear units are being built. One will open in 1972, the other in 1973.

Well within the next four years, the total capacity of our nuclear stations will be 5,200,000 kilowatts, 26 times what it is today. That is far more electricity than the entire city of Chicago now uses.

By then, we will have spent nearly one billion dollars to develop nuclear power, to keep pace with your growing demand for electricity without emitting pollutants.

We have spent and are spending millions more for the most modern dust-collecting precipitators, for gas turbines, and for the conversion of coal-burning units to other fuels.

Commonwealth Edison's total activities to reduce and prevent air pollution add up to the greatest single effort we know of to clean the air.

DEFENDANT'S EXHIBIT 101

COAL STRIP MINING - IS IT REACHING A PEAK?

by

Hubert E. Risser
Assistant Chief and Principal Mineral Economist
Illinois State Geological Survey
Urbana, Illinois

For about half a century, strip mining has been providing an ever-increasing share of total coal output in the United States, and in the past 30 years this share has grown from less than 8 percent to 33.7 percent, as shown in Figure 1. The graph also shows that strip mining is gaining faster in the West than in the East.

From 1961 to 1967, output from strip mines grew 63.6 million tons, or 52.2 percent. Certainly there is nothing in such performance to indicate any peaking in the level of strip coal-mine production. But the fact is that, if not in actual tonnage, strip mining appears to be reaching its peak in relative importance, at least east of the Mississippi River. And the area east of the Mississippi provides 90.0 percent of the strip and 94.9 percent of the total coal production of the nation.

The relative economic advantage which spurred strip mining's growth for a third of a century has been diminishing markedly in recent years. Figure 2 shows evidence of this decline. From 1947 until 1961, strip tonnage output remained fairly stable, at the end of the period showing only a 12.5 percent decline. Meanwhile, underground coal production fell 44.5 percent. As the result of the greater decline in underground coal, strip coal in 1961 furnished 30.3 percent of the total coal produced, compared to only 22.1 percent in 1947.

In the succeeding 6 years, however, underground coal output increased by 76.5 million tons, while strip output increased only 63.6 million.

Further evidence of the strengthening of underground coal's relative position - or if you will, the weakening of strip coal's position - can be found in the major coal stripping states, Illinois, West Kentucky, Ohio, Pennsylvania, Indiana, and West Virginia, which in 1966 provided 80 percent of the nation's strip coal. Figure 3 shows what has been happening in three states lying in the Appalachian field and in the total output of these three states. In the figure, the column height represents the output of coal mined by all methods. The number at the base of each column is the percentage mined by stripping.

Presented at the Fall Meeting of The Society of Mining Engineers, Minneapolis, Minnesota, September 18, 1968.

In Pennsylvania and Ohio, the percentage of strip mining increased between 1956 and 1961, but by 1966 had declined from the 1961 level. In West Virginia a decline occurred during the first 5 years but was followed by a rise.

In January 1968, Coal Age published an article listing the locations and capacities of new large mines in the planning and construction stages that would be operating by 1968-1971.

The plans for West Virginia and Pennsylvania indicated all the new mines would be underground. Except to the extent they might replace existing underground capacity, the new mines will increase the dominance of underground coal. Announced capacity for Ohio is 24.7 percent strip, which is much below the present level.

Figure 4 shows similar data for Illinois, West Kentucky, and Indiana individually and combined. The percentage of strip mining grew for each of the 5-year periods in Illinois and West Kentucky. During the second 5-year period, however, the increase was considerably less. In these states the projected new capacity should also exert a downward pressure.

Alone among the states illustrated, Indiana shows a strong tendency toward an increase in the relative position of strip mining.

If strip mining actually is destined to provide a smaller share of total coal output, as the evidence indicates, the cause must lie in a diminution of the economic advantage that strip mining has enjoyed in the past. The narrowing of this advantage appears to be taking place in a number of ways.

PRODUCTIVITY OF WORKMEN

From the beginning, the output per man day, or as it is more commonly stated, manshift, in strip mining has been well above that in underground mining. Figure 5 shows the increasing spread in tons per manshift in strip and underground mining. In 1943 the figures were 15.46 tons per man day for strip mining compared to 5.04 for underground mining. With the improvement of methods and equipment during the succeeding two decades, the output per manshift by 1966 had risen to 33.6 tons for strip and 14.6 tons for underground mining.

Despite the increasing spread in average productivities, the difference in labor costs per ton between the two methods has been diminishing. The reciprocal of tons per manshift, or the fraction of a manshift per ton, provides better comparison of cost, for it is a measure of the time spent on a unit of output. Man days per ton are shown in Figure 6. Also shown is the decline in the margin of advantage held by strip mining. Whereas in 1956 it took an average of .069 of a shift more labor to produce a ton by underground mining than by strip mining, in 1966 the difference was only .039 of a shift. If, for example, we assume an average wage of $28.00 per shift for both types

of mining, then stripping's margin of labor advantage would have been reduced from $1.93 to $1.09. More accurate comparisons of changes over a period of time must, of course, consider changes in wage rates and different wage rates for different types of labor.

Figure 7 shows changes in the margins for five important strip mining states. In all areas, the margin has been shrinking. The size of the margin in labor costs is, of course, only one of the things that govern whether strip or underground mining will be used. Many other factors, both physical and economic, are involved.

OVERBURDEN AND STRIPPING EQUIPMENT

As strip mining has progressed, the average depth of overburden and the ratio of overburden to coal have been gradually increasing (Figure 8). The reported average depth of overburden for coal strip mines in the United States increased from 31.6 feet in 1946 to 41.6 in 1955 and to 50.1 in 1965. Cubic yards of overburden per ton of coal increased from 9.1 cubic yards in 1946 to 12.3 in 1955 and to 12.8 in 1965.

Figure 8 shows changes in the thickness of both overburden and coal in strip mines of the major producing areas. The thickness of coal mined has, in general, remained relatively stable, and in some states the reported average ratio of overburden to coal has shown no major change. In all states, however, the average depth has changed significantly. Not shown on Figure 8 is the increase in maximum depth, which in some states now exceeds 100 feet.

The use of larger equipment has enabled coal strippers to handle the thicker overburden economically, either by using larger single units or units working in tandem. Since the mid-1950s, shovel capacities have increased from about 65 cubic yards to 115 cubic yards in 1959 and to 180 cubic yards in 1966, with still larger shovels scheduled soon. Draglines have shown a similar growth in size. While such equipment is physically capable of moving deeper and deeper overburden, the performance increase is not always proportional to the investment cost. For example, a 100-cubic yard shovel operating at a depth of 92 feet can handle somewhat more than twice the volume of a 45-cubic yard shovel operating in 52 feet of overburden. But operating under these conditions for the same thickness of coal, net increase in coal availability would be less than 20 percent. Since the purchase price of the larger shovel will be two to three times that of the smaller, shovel investment and depreciation per ton of coal, as well as shovel operating costs, are greatly increased. Thus, the margin of cost, or the advantage of stripping over underground mining, tends to narrow with the depletion of shallow reserves and increase in overburden thickness.

RESERVE REQUIREMENTS AND COSTS

During the 32 years from 1935 through 1966, the cumulative total of coal strip mined in the United States was almost 3.5 billion tons. Even if it were assumed strip mining were to show no annual tonnage gain and remain at its 1966 level, the next 3.5 billion tons would require only slightly more than 18 years to produce.

U. S. Bureau of Mines figures show that the average thickness of coal mined by strip mining in 1965 was 5.2 feet. Calculations based on this thickness indicate that the mining of 3.5 billion tons would require the uncovering of 466 thousand acres of coal, assuming coal in the ground at 1800 tons per acre-feet and 80 percent recovery.

The problem of future reserves of strip coal will not be as much one of scarcity as of availability. Studies by the Illinois State Geological Survey indicate that in Illinois alone the coal lying under overburden of 100 feet or less thick amounts to more than 3 times 3.5 billion tons. The problem, east of the Mississippi, at least, will be one of piecing together coal and surface rights to make a block sufficiently large for an economical operation.

Large outputs over a long period of years are required to justify and amortize the investments in equipment for handling thick overburden. In 1965 the outputs of the 10 largest strip mines in the United States ranged from 2.2 to 3.8 million tons. Twenty-five years' output would be 55 to 95 million tons. In 6-foot coal at 80 percent recovery, 4770 to 8246 acres would be required. In 4-foot coal the acreages would be increased 50 percent. For most economic mining, each acreage should preferably be in a single block to avoid the moving of giant equipment. Coal stripping companies, unless they already possess the required reserves, will face increasing difficulty in piecing together blocks of such size.

RECLAMATION

Progressive strip mining operators have engaged in stripped land reclamation for many years. In recent years, however, states in increasing numbers have been passing new and more stringent laws governing the type and degree of reclamation or restoration that must be attained. The cost per acre reclaimed for any required degree of reclamation depends on many things, among which are the depth of overburden, the type of stripping equipment that has been used, and the chemical and structural character of the overburden material.

Reported reclamation costs for acreages of coal lands reclaimed in 1964 ranged from less than 100 dollars per acre for partial reclamation of one small area to almost 1000 dollars per acre for another area. The overall average for partial reclamation of 11,185 acres was 149 dollars per acre. Average cost for completely reclaiming 21,541 acres was reported at 230 dollars per acre.[1]

Figure 9 shows the cost per ton of coal for various thicknesses of coal at an assumed cost per acre reclaimed.

That increased requirements for reclamation will bring increased costs for strip mining has been recognized by TVA and that agency's contracts for coal are based on prices that cover these costs.

LAND ACQUISITION COSTS

There has been a steady rise in land and real estate prices in recent decades. U. S. Department of Agriculture indexes of the average value of farm land and buildings show the following changes:

	Index 1957-1959 = 100		Percent increase
	1960	1968	1960-1968
U. S.	111	170	53.2
Illinois	106	156	47.2
Indiana	107	165	54.2
Kentucky	112	175	56.3
Ohio	105	153	45.7
Pennsylvania	111	171	54.1
West Virginia	110	150	36.3

The average total increase for the United States in the 8-year period was 53.2 percent. The increase varied considerably from place to place. For individual states shown, it ranged from 36.3 percent in West Virginia to 56.3 percent in Kentucky. However small or great the increase, wherever surface rights must be acquired land price trends are one more factor diminishing the economic advantage that strip mining possesses.

Figure 9 can be used to estimate the effects of inflation in land costs. If, for example, the land cost in an area where coal averaged 4 feet thick were to increase from 400 dollars per acre to 600 dollars per acre, the cost per ton of coal would increase 3.48 cents.

SUMMARY

For half a century the percentage of coal production provided through strip mining has steadily increased. Recent trends indicate that a peak in percentage, if not in tonnage, is being approached. Important among the reasons for this is the decline in economic advantage enjoyed by strip mining compared to underground mining. Among the factors contributing to this decline are the following:

1. Decrease in the margin of advantage in manpower requirements held by strip mining.
2. Increase in depth and volume of overburden necessitating larger equipment and investment of more capital.
3. Increasing scarcity of reserve blocks of land big enough to support extensive mining operations.
4. Increasingly stringent legislation for reclamation of stripped land and the resulting higher cost of reclamation.
5. Increasing cost of land surface rights..

1/ Surface Mining and Our Environment, U. S. Department of the Interior, 1967, Appendix I, Table 5.

In the eastern part of the United States there has already been a peaking and decline in the relative importance of strip mining in some major coal producing states. Although it is not clear at what point the pressures discussed above will cause a peaking for the region as a whole, the trends indicate that this definitely is on the way.

In the less populated states of the West, some of the pressures are less severe. This is especially true of those pressures related to conflicting or competitive land uses that affect the availability of reserves and cost of land. The other pressures, although they may not become sufficiently strong to cause a decline in western strip mining's relative importance, will, nevertheless, reduce to an increasing degree the advantage that strip mining has possessed.

CHAIRMAN ANDERSON'S MEMORANDUM OF TRANSMITTAL

SEPTEMBER 21, 1962.

To the Senate Committee on Interior and Insular Affairs:

I am transmitting herewith to the members of the Senate Committee on Interior and Insular Affairs and the ex officio members of the fuels policy study, as well as to other interested parties a staff report prepared for the committee as an assessment of available information on energy and fuels in the United States.

This study was initiated and conducted under authority of Senate Resolution 105 of the 87th Congress, 1st session. The study report was prepared by a special study group of experts recruited by the committee specifically for this task. The chairman of the study group is Mr. Samuel G. Lasky, an official in the Department of the Interior, and the members of the group are made up of professional men from private industry who were selected after conferences with and recommendations by spokesmen for our fuels industries.

I want to commend these gentlemen individually and as a group for their cooperation during the conduct of the study. As a result of their diligent efforts, in less than a year our committee has before it in a single volume pertinent information relating to fuels and energy essential to any further consideration we make of this important subject. I am particularly grateful to the chairman of the study group who was of great assistance to the committee in helping to meet promptly the deadline set for the study group's report.

In my view, our committee has been charged by the Senate with two main tasks under the authorizing resolution. The first was to gather the facts and figures pertaining to fuels and energy. This has been done in the present study. Our second and final task will be to study the information provided and, if it is the wish of the committee, to report our policy findings and recommendations to the Senate.

To help the committee with this task, we are distributing this study and inviting comments and suggestions which, when received, will be carefully considered in reaching any decisions respecting recommendations for congressional action. When the Interior and Insular Affairs Committee meets early in the 88th Congress, our assignment can be then completed.

I am convinced that the study group has made a real contribution to this Nation's store of knowledge on a complex and all-important subject, and that its report will prove of great value to the Government, to our fuels industries, and to the public.

CLINTON P. ANDERSON,
Chairman, Senate Committee on Interior and Insular Affairs.

LETTER OF SUBMITTAL

U.S. SENATE,
COMMITTEE ON INTERIOR AND INSULAR AFFAIRS,
September 7, 1962.

Hon. CLINTON P. ANDERSON,
Chairman, Committee on Interior and Insular Affairs,
U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: We are honored to present herewith to the Senate Committee on Interior and Insular Affairs our assessment of the available information on energy in the United States. The report is the result of roughly 10 months of effort; although work was started as early as August 1961, the study group was not fully assembled until November. More information could be included, and the analysis made a little more penetrating, here and there, but the broad conclusions to be derived would remain unchanged and we do not think the additional time and effort would be justified.

The report presents first a brief historical and economic perspective, examines current opinion about future consumption of energy, considers one by one the various determinates of supply (reserves, plant capacity, transportation, labor supply and productivity, technology, marketing, competition, and like influences), and then compares the estimated future consumption with the Nation's ability to supply it. The years 1965 and 1980 were selected as check points. Emergency as well as peacetime demand and supply are covered. A subsequent chapter discusses the economic and social costs of various policy directions, and the last chapter of all presents the opinions of industry and consumer groups as to what they think national fuels and energy policy should be, in their own words.

Your instructions regarding the making of this study are presented in the introduction to the report. In brief, the instructions were to assemble the information that is currently available, to study it, and to assess its worth. In doing so we found ourselves continuously dismayed to learn how little positive information exists, how much is impression and folklore, in subject area after subject area, in industry after industry. Belief in this folklore is deep and it is held with passionate, though honest, tenacity. Too often, to our minds, have we been forced to write: "No one knows * * *." One result of this set of circumstances is that our report contains occasional statements that do not have the complete endorsement of one or another of the members of the study group. All this we have tried to record faithfully and objectively. Yet despite the imperfect fabric of fact, we think there has emerged from this study a reasonably good picture of energy in the United States and of the policy, legal, and regulatory framework within which it sets. It is our earnest hope and belief that we have given you and your committee the information you want.

Through you we want to acknowledge the generous and expert cooperation provided us by many Government agencies, trade associations, companies, and individuals in providing us with information and in checking our draft report. The credit for whatever value this report may have must be shared with them.

Respectfully submitted.

NATIONAL FUELS AND ENERGY STUDY GROUP,
SAMUEL G. LASKY, *Chairman.*

REPORT OF THE NATIONAL FUELS AND ENERGY STUDY GROUP

SUMMARY

The basic purpose of this report is to compile and assess an existing body of information, and hence the report does not readily lend itself to being summarized in the usual sense. Nevertheless, we have tried here to condense the information and to indicate its drift in such a way as to give the reader a useful guide, so that he may be able to select such part of the contents as he wishes for detailed reading.

REQUIREMENTS

There is a reasonable consensus among the experts that the Nation's projected requirements will nearly double by 1980 (to about 82 quadrillion B.t.u.'s), that generation of electric energy will multiply by some 3½ times (to about 2,700 billion kilowatt-hours), and that consumption of oil will increase by about two-thirds (to, say, 5.7 billion barrels). The consensus for coal, gas, and nuclear energy is not so clear cut, but the following deductions have been accepted as usable for the policy-tailored framework of this report: coal consumption roughly to double by 1980 (to 800 million tons or more), gas almost to double (to 20 trillion cubic feet or more), hydropower generation to drop from a share equal to 4 percent of total energy consumption to about 2½ percent, and nuclear energy to increase to a level about equal to hydropower.

Quantitative estimates of emergency requirements—a euphemism for wartime requirements—are meaningful only in relation to a near-future contingency. For this and other reasons, we assume that the nonmilitary part of wartime requirements will be within the margin of error inherent in the peacetime figures projected for 1965: i.e., 11 million barrels of oil a day, 15 trillion cubic feet of gas a year, 500 million tons of coal a year, and 1,100 billion kilowatt-hours a year. For oil there would be an additional military demand approaching 3 million barrels a day.

These figures do not apply to nuclear war, of course. In the period immediately following an attack, the civilian population would have to get along with such quantities and kinds of fuels as are at hand locally. We presume that the military arm has petroleum fuels in hand to support the immediate retaliatory blow. The demand for petroleum products would increase as military action mounts, and the demand for all forms of energy would increase as national authority is restored and industrial activity is resumed. The top limit of this increase is conditioned by how long the war would last and the course it takes. All energy demands would remain high during the period of reconstruction.

SUPPLY

The Nation's resource base, in terms of each fuel, is adequate to meet projected requirements for the period covered by this study—i.e., to 1980. The 20 billion tons of coal even now commercially available (reserves) is more than enough comfortably to support a 1980 coal output of even as much as 800 million tons. There is plenty of oil in the ground but one or more steps may be needed to realize it: rate of exploration be stepped up, more attention be given to secondary recovery, ratio of reserves to rate of output be established at some figure well below the usual range of 12 to 14. The Nation has the ability to be self-sufficient in oil if it so wills. Imports could be called on if desired, there being no dearth of foreign oil, and so could the oil in oil shale. Oil shale may in fact actually be yielding oil well before 1980, and coal may be yielding gasoline. The domestic supply of gas available appears to be safely well above the projected requirement. High B.t.u. gas from coal is in the near offing. A comparison between projected consumption of electric energy (regardless of source) and the ability to supply it yields the prompt and simple answer that there should be no difficulties in that area. While nuclear power faces several problems, it is an accomplished technological fact.

Conventional fossil fuels plus shale oil and fissionable materials contain recoverable energy equivalent to 800 years of usage at the current rate. Improvement in nuclear technology could expand this figure eightfold. This outlook is without the benefit of foreign supplies, fissionable materials available at prices higher than those now paid, coal and shale oil beyond the limited quantities assumed to be recoverable, or the energy potential of unconventional sources.

There is also a large present plant capacity and apparently an industrial ability to generate the funds to expand the capacity as needed. Labor supply should pose no problems; the only sector about which doubt has been expressed is in regard to coal miners; and here it appears that, because of expected continued improvement in output per man-day, the 800 million tons of 1980 conceivably could be produced by a labor force even smaller than the force presently at work.

Transportation has sometimes been considered a bottleneck in the energy complex. The concern appears exaggerated. Transportation of oil and gas is a matter of investment. An aggressive research on extra-high voltage transmission almost assures continued economic transportation of electric power. The only real question relates to a shortage of railroad cars for the movement of coal. Such shortages as occur are not the result of a shortage of cars as such but of cars that are serviceable. The railroads repair damaged cars only as traffic demands it, and a shortage results when business picks up faster than ability to repair the cars. Whether or not shortages have ever limited the total supply of coal to the country, or have caused coal users to turn to other fuels, is a matter of conflicting opinion.

In a nuclear emergency, the Nation will have to rely initially, as indicated above, on the supply locally available, but there would be such great destruction of consuming equipment and plants that the supply would be generally adequate. Further supply should be available as quickly as it is called for by restoration of the economy. For other war or war-related emergency, the national capacity for producing

oil products seems to come close to equaling, or even exceeding, total wartime demand. This is without regard to imports, but so much judgment is involved, and the problems of wartime requirements and logistics are so complicated, that the subject needs deeper analysis than we can give it. Both coal-producing capacity and labor supply are large enough to meet emergency coal demand. Gas-producing capacity and electric-generating capacity are adequate. Information on wartime transportation capability regarding energy is scanty and conflicting, but seemingly there would be no dire problems within the United States itself. Ocean transportation encompasses military problems outside our purview.

COST AND TECHNOLOGIC PROGRESS

Implicit in the above commentary about the Nation's ability to meet its needs over the next 20 years is an assumption about the ability of continued technologic progress to hold costs within limits. In part this is a matter of faith, albeit faith based on the record. How much oil, gas, and coal will be produced, and how much electricity generated, are matters of economic decision, which resolve into incentives for exploration, research, and development and for investment in plant to transport what is produced or generated. Incentives are related to ultimate profits, which are related to costs. Information on costs is elusive and inconclusive, but at least for oil and gas jointly there seems to be little discernible trend either upward or downward in real terms (dollars of constant value). None of the three principal fossil fuels seems likely to price itself out of any major markets within the time span of this report. In any case the cost of oil from shale should place an upper limit on the price of crude oil, and the cost of gasifying coal a limit on the price of natural gas; all these will impose restraints on the price of coal.

The cost of transportation is a vital part of the delivered price of energy. The coal pipeline, the integral train, mine-mouth generation coupled with extra-high-voltage transmission, larger diameter oil and gas pipelines, and other developments should hold transportation costs down.

INTERFUEL COMPETITION

Use of coal has been going down in the face of an increasing national consumption of energy. The three fuels—coal, oil, and gas—compete with one another for the electric energy, space-heating, and process-heat markets; electric energy (including hydropower) competes with coal, oil, and gas for parts of these same markets.

Competition results from the ability and willingness of the customer to shift from one product or supplier to another. Many factors influence this freedom of choice. One is the physical character of the fuels. The solid nature of coal and the liquid nature of oil generate advantages and disadvantages for each, both with respect to cost in their competition with one another and with gas and with respect to esthetic preference.

A second factor is adequacy and assurance of supply, and a third is the delivered price. Delivered price is related to transportation. Cost of transportation is the reason why interfuel competition is so

severe in those areas having little or no native energy resources, as in New England particularly. Railroad transportation of coal comes high, compared to the cost of moving oil or gas, constituting on average throughout the United States more than four-tenths of the delivered price of bituminous coal.

All the major fuels, including coal, are produced and transported as though jointly with coproducts or byproducts. Electricity, too, is sometimes a joint product, and transportation also has its joint-product aspects. The economics of joint products influences the pricing of the main product.

One aspect of the influence of technology has been referred to above. Of more immediate relevance to competition is the technology of use, which has acted particularly to the detriment of coal. Prime examples are the change from steam to diesel railroad locomotives and the substitution of oil and gas for coal in home heating.

Fuel competition is related also to the propinquity of fuel source to market, which is a shifting circumstance, and of course to the common phenomenon of consumer preference.

A final factor is the framework of policies, laws, and regulations within which the competition operates, summarized separately below.

POLICIES, LAWS, AND REGULATIONS

Federal, State, and municipal governments all have laws and regulations relating to energy. The Federal Government leaves local energy problems to local regulation. In addition, the policies of foreign governments have their impact on American supply and demand.

Federal legislation and policy in the field of energy covers foreign trade, production of raw materials, electric power generation, production and sale of natural gas, transportation, research, taxation on production and use, maritime laws, and foreign relations. State and local regulations apply mainly to conservation of oil and gas and cover also taxation on mineral production and use, public utility regulation, and air pollution.

Policies of foreign governments relate to their control over the importation of American coal and to their reaction to U.S. restrictions on importation of oil and oil products. Canadian policy occupies a special niche, because of the contiguity of the two countries. The U.S. imports both gas and electricity from Canada, which imposes restrictions on the outflow of both.

Some policies, laws, or regulations tend to limit production and to raise price, some to lower price; some specifically restrict end use.

POLICY ISSUES

Twelve policy issues have been identified as justifying discussion. These include the sale of natural gas to industrial consumers under interruptible rate schedules, importation of residual fuel oil, importation of crude oil and products other than residual fuel oil, importation of natural gas from Canada, development of a domestic shale industry, the role of Government-sponsored research, domestic self-sufficiency, whether action is necessary to insure that U.S. emergency needs can be met from the Western Hemisphere alone, legislative or regulatory control of the use to which a fuel may be put, Government

encouragement of electric transmission interties, how to handle the problem of unemployed coal miners, and granting of right of eminent domain to coal pipelines.

Whatever policy direction may be followed with respect to each of these, various costs and gains are involved—to the Treasury, to the consumer, to the gaining and losing industries, and to society. Some of these gains can be quantified, mostly they cannot. In fact, it is not possible always to isolate them, or to trace out the specific effect of a policy action. Action taken may better one situation, worsen another. Questions that cannot be answered insist on intruding, such as: What is the cost to society when in the pursuit of some goal a desired product or service is denied? Or, what is the cost of withholding the fruits of technologic innovation or of dampening investment?

Energy policy relates to other policies, either explicitly or indirectly, and some energy policies indirectly affect policy in other areas. The important involvements are with transportation, taxation, trade policy, international policy other than trade, national defense, and various Federal programs, particularly atomic energy. Other areas of policy involvement include antitrust legislation, care and development of the inland waterways, space exploration, air pollution, labor, and urban redevelopment.

The three policy issues that are currently of most intense interest are:

Interruptible gas

In 1960 total interruptible sales totaled 2.1 billion Mc.f. Most of this is sold in geographic areas not economically served by coal, and some is sold for noncompetitive uses. In all, about one-fourth (or the equivalent of 22 million tons) is in direct competition with coal.

The price charged for interruptible gas is less than that charged for firm service and at least covers the cost of the gas itself plus the out-of-pocket costs of transportation and distribution. Thus this type of service makes a contribution toward fixed charges that would otherwise be borne by firm customers. In 1960 this fixed-charge contribution aggregated $400 million nationally.

Residual fuel oil

The use of residual fuel oil in the United States has remained fairly uniform over the past decade, but on the east coast, where most of it is consumed, net imports for domestic consumption have been rising and in 1960 were the equivalent of about 40 million tons of coal. Such imports come largely from the Caribbean where heavy fuel oil is the major refinery product. These imports affect the production of coal primarily in Pennsylvania, Virginia, and West Virginia.

Coal mine unemployment

The number of workers engaged in coal mining has been declining almost steadily from a peak of about 875,000 reached in the early 1920's. It is now only about 150,000. The number of unemployed is estimated at 100,000.

About half the decline has resulted from loss of markets and half from improvement in the efficiency of production. For bituminous coal the fractions are about one-third due to loss of market and two-

thirds to improved efficiency. The average miner produced 2,450 tons in 1960, as against 1,350 tons a year during the midforties when coal output reached its peak, and about 750 tons a year in the early twenties when employment reached its peak. Concurrent with loss of markets, coal-mining wages were rising and were among the highest in American industry, and this element of cost has been a major factor in pushing the industry into mechanization during the postwar period, in order to stay competitive.

Elimination of interruptible gas sales and of the importation of heavy fuel oil would increase employment in the coal industry, but for a number of reasons (among them that part of the vacated markets would be taken by domestic oil and by firm gas and that the current coal work force is used less than full time) the gain would be small—perhaps a few thousand men—in terms of the gross problem. Each million tons of added coal production would represent the employment of 400 miners at today's average output per man-day and at the average current workweek of less than 4 full days; at the current workweek but at the output per man-day projected for 1965, each million tons would represent the employment of 285 miners.

INDUSTRY AND CONSUMER POINTS OF VIEW

The point of view held by producers and consumers of energy as to what policy should be is as much a piece of information as is a table of statistics or description of a piece of technology. In order to provide as full a body of information as possible, we have invited the points of view of 12 groups, each representing either a producer of one or another form of energy or a consumer. These are included precisely as received. It would be a disservice to these groups to summarize their statements, for interpretation unavoidably would insinuate itself, and therefore we have not done so.

INTRODUCTION

The scope of this report

Senate Resolution 105 (87th Cong.) instructs the Senate Committee on Interior and Insular Affairs to undertake a study of the supply of and demand for fuels and energy in the United States. The study is intended as a basis for possible revision of fuels and energy policy, including the possibility of new legislation. The inquiry has three parts: (1) a study of the present and future energy requirements of the Nation and of its ability to meet those requirements; (2) a review of existing laws and policies with respect to their effect upon energy supply and demand; and (3) consideration of policy.

The first two parts are factfinding operations and constitute the subject of this report. The instructions given to the authors of it by the Senate Committee on Interior and Insular Affairs were simple and clear, as follows:

1. To prepare for the committee, within the objective of Senate Resolution 105, as accurate a story as possible, in simple and nontechnical language, about the economic and technical aspects of energy demand and supply in the United States.

2. In doing so, to deal with existing information only or such new information as can be assembled in short order.

. . . And its purpose

The first instruction constitutes a direction to sift out the fact from the nonfact in the existing body of information—to scrub the facts clean, so to speak. There are many persons who will say that the facts are clean enough as they are. That may be, as those persons see the facts. But Congress is not composed of experts in the demand and supply of coal, or oil, or gas; in the intricacies of electric generation, transmission, and use; in the potentials of atomic energy; in the possibility of needing and getting energy from the sun, or wind, or the tides, or of using heat brought up from deep in the earth.

What purports to be fact is not always indeed fact. The only bits of information that everyone can agree on are the bald statistics themselves and even that circumstance does not always hold. Often the so-called fact represents judgment, impression, informed guess, overstatement, prejudice, or sometimes plain fiction. Professional judgment and impression are invaluable when facts are short, but they are not a substitute for fact itself.

The element of prejudice must be particularly suspect. In relation to this study, there are two kinds: the honest prejudice generated by a person's loyalty to his profession or his firm, and the biases inherent in professional theory. There are various schools of thought on how to calculate mineral reserves, for example. Those who estimate reserves of coal, oil, and gas each believe that the occurrence and economics of his commodity are unique and demand unique definitions and criteria. A figure on reserves is thus not an immutable fact, but,

in the first place, involves considerable judgment and, in the second place, is conditioned by the business economics of the industry.

A second example is in the methodology of making projections. There are two major schools of thought on how projections are to be made, and each contains subschools. The adherents of each school are honestly convinced about the correctness of their methods, but however positive they may be, the figures they come up with are not fact. Considering the wide ranges in projections of future use of energy, for example, made by different experts, the figures certainly are not the kind of "fact" upon which Congress should properly be asked to anchor anything so serious and far reaching as national policy.

The first intent of this report, then, is to assemble the facts as meticulously as possible. Where facts run short and judgment must be used, the report points out where the judgment enters; where informed guesswork must be resorted to—and it is resorted to only where necessary—that is clearly flagged for the reader's attention. Where the facts are too scanty for even that, the reader is informed of that, too.

Volumes of information are available. If stacked one on top of another, the statistical compilations, analyses, and reports relevant to the present study would make a pile many feet tall. A list of those that have come to our attention appears as an appendix to this report. The amount of information of one kind or another is so impressive as to appear to obviate the need for time-consuming and costly new studies. Part of the purpose of this report is to find out if that is true—to find out if it is necessary too often to resort to guesswork in clarifying the economic and technologic basis of policy consideration.

The approach

The method used herein in approaching the purposes stated above is to analyze the energy needs of the United States and then to measure against them the supply of energy that can be made available. At the same time and within this framework, and in order to keep the study oriented toward its main purpose as an aid to policy consideration, the report keeps its eye on the gathering and analysis of information specifically needed to clarify the policy issues brought to the attention of Congress during the hearings on Senate Resolution 105.

Preparation of the report has exposed an assortment of additional policy issues. These are indicated. Indicated also are alternative approaches to these issues, an assessment of the costs of each alternative, and the extent, if any, that the various alternatives may violate the technologic and economic situation, in order that Congress may know of them in considering the political and social factors that it must deal with in policy determination.

How far into the future?

Senate Resolution 105 specifically refers to "prospective fuel and energy resources of the United States—and probable future rates of consumption thereof." How far into the future should one attempt to peer? The authors of this report have concluded that 20 years is a good compromise between impulse and reality. It is far enough

into the future to offer perspective for policymaking, yet is not so distant as to preclude reasonable assessment of future demand and satisfactory judgment as to the trends of the technology and economics of production. We can judge within reasonable limits, for example, what may be the technology of the production of coal, oil, and gas by 1980, and what may be the effects of this technology on costs of production, whereas anything beyond that date gets deeper and deeper into unnecessary speculation. At the same time, 20 years is distant enough to permit necessary adjustments in policy if such adjustments become necessary.

The year 1980, then, is taken as the terminal checkpoint for this report. The reader is cautioned to remember, however, that "1980" does not mean that specific year, but, rather, the general period of time clustered around it. The crystal ball available to authors of this report is not clear enough for them to predict what may happen in any given year. A glance at economic ups and downs exposed in any historical record prove how impossible that is. The reader may consider this to be an unnecessary caveat, yet experience proves that projections and the analyses made from them almost invariably run afoul of the public's inclination to hold the forecaster to the specific year.

Assuming that the study called for by Senate Resolution 105 leads to new legislation, it will, perforce, be a while before the legislation takes effect. This factfinding report must be studied, its information married to other considerations, and legislation studied, written, and debated. The new legislation and policy will apply to conditions as they then exist; 1960, the latest year for which statistics were available in preparing this report, and 1961 and 1962 the years in which the study was made and the report written, will be history. Accordingly, the authors have striven to project economic and technological conditions to, say, 1964 or 1965 as a base year.

PART I. ENERGY IN THE ECONOMY

USE PATTERNS

The ways in which energy is used at any given time are a function of the technology of use, the competitive ability of producers of the raw energy (including electricity) to deliver the energy to the consumer, availability of the raw forms, and preference of the consumer.

At any one time, one or another of these several factors dominate, at a different time another dominates. When wood was at hand for the taking, it was used, and the technology of use was adapted to the characteristics of wood. But when coal deposits were discovered and developed, coal's capabilities so far outstripped those of wood that the use technology was modified to suit—and the modification induced additional development of coal production. The growth of iron and steel production and that of coal also went hand in hand, as did, later, petroleum and automotive transportation. Petroleum brought gas with it, but use had to wait for a technology of transportation to be developed. With gas, consumer preferences were and are particularly important. Concurrently, gas was found to have unique properties that make it peculiarly useful for some purposes. Figure 1 shows the historical development of relative usage.

TABLE 1.—*Fuel consumption by sector, 1955*

[Trillion B.t.u.]

	Coal	Oil and natural gas liquids	Natural gas	Total
Industry	5,012	2,722	4,081	11,815
Commercial	896	763	603	2,262
Households	938	2,549	2,239	5,726
Transportation	333	7,430	254	8,017
Government	(1)	821	293	1,114
Agriculture	(1)	616	(1)	616
Miscellaneous	(1)	1,794	1,654	2,848
Electric generation[2]	4,242	630	1,384	6,256
Total	11,422	17,325	9,908	38,635
Total, 1961	10,224	20,412	13,428	44,064

[1] Included in other categories.
[2] Hydropower not included.

NOTE. Totals do not add due to rounding.

Source: Schurr and Netschert with minor adjustments; 1961 Bureau of Mines.

Table 1 shows the pattern of use by consuming sector. Of this pattern, a fifth to a fourth of coal use is nonfuel (for coke), some uncertain but small use of gas (for carbon black and petrochemicals), and an eighth of oil use (petrochemicals, lubricants, wax, coke, road oil, asphalt).

Coal is preeminent in the generation of electricity and is assumed by students of the subject to continue preeminent for some time in

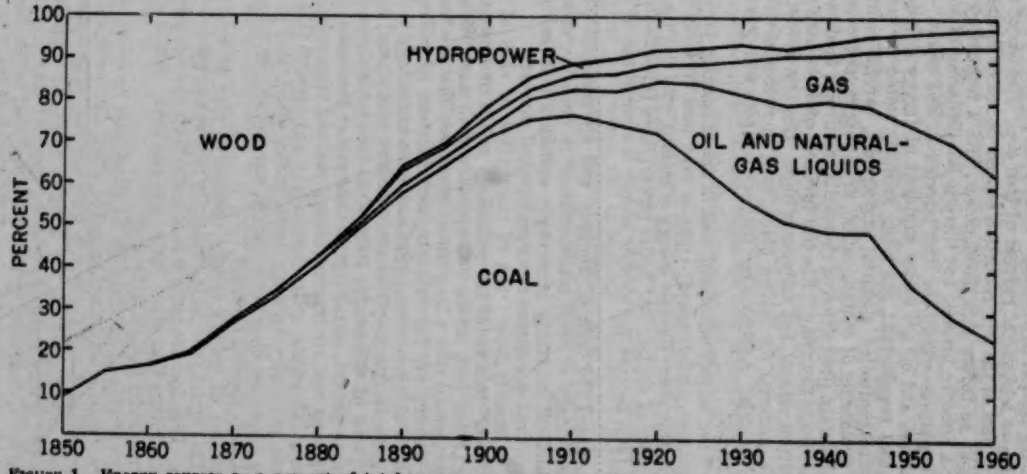

FIGURE 1. Energy sources as a percent of total energy consumption. (After Schurr and Netschert; 1960 figures based on Bureau of Mines data.)

this usage over the Nation as a whole. Coal is uniquely suitable, in the form of coke, as a chemical reducer of iron ore. The use of oil or natural gas in part of the iron-reduction process decreases the need for as much coke as before this development, and a technology is developing for a noncoke process, but there is no displacing of coke entirely for this purpose within the time purview of this report.

Coal, natural gas, and oil are major suppliers of energy in industrial processes that require heat, gas being uniquely suited for processes that require controlled chemical atmosphere, careful control of the heat, or avoidances of contamination, as in forging operations, heat treating of metals, production of chemicals and drugs, food processing, and glass manufacturing. Electric furnaces could be used for precise temperature control, but the cost is high. Gas also is ideally suited as a raw material for carbon black, used in rubber making, and for petrochemicals. And no other fuel can compete with gas for use in the field itself.

Oil and gas have largely displaced coal in space heating, largely because of consumer preference, and gas is even now limiting the growth of oil in this use. Electric energy is moving into this usage, but, except in areas of nuclear and hydro power, there is no displacement of fossil fuels because the electric energy is created out of one of them.

Oil has preempted the field of highway and air transportation, because the technology of such transportation is designed around liquid fuels, and oil currently is strongly entrenched in railroad transportation. Coal dominates the metallurgical market.

To attempt to specify how much of the market of each of the basic fuels is "safe," because of the technology of use or because of the properties of the fuel, would be impossible with any precision and in any event would take a long time. Some uses that are "safe" now may not remain so; for example, electrification of railroads could eliminate diesel locomotives. (See section on technology.) But the following gross fractions appear reasonable at present and up to the first checkpoint of this study, 1965: Coal—six-tenths (most of the electric utility market, metallurgical coke, use at the mines); oil five-tenths (highway and air transportation, railroad transportation for the present, lubricants, petrochemicals); gas—four-tenths or more (field use, petroleum refining, some carbon black and petrochemicals, uses requiring close temperature, atmosphere, or contamination control, some spacing heating).

About 35 percent of today's energy demand is free of interfuel competition. This figure represents essentially motive energy now met by liquid fuels. This does not mean that this market is noncompetitive within itself but rather that other fuels—gas and coal—cannot effectively penetrate it under today's technology.

At the other extreme of competition lie those uses in which coal, oil, and gas are immediately interchangeable, when dual or three-way equipment is maintained and the switch from one fuel to another can be accomplished immediately on the decision to do so. About 45 percent of the 802 utility stations reporting detailed information to the Federal Power Commission in 1960 were equipped to handle two or three fuels. In regions I, II-A, and III (as designated by this study), which constitute our "eastern seaboard," 27 electric utility

plants were equipped to burn only oil; 116 to burn only coal; 51 to burn oil and coal; 16 to burn coal and gas; 19, oil or gas; and 25 to burn all three. Thus, of the eastern seaboard's 256 steam electric plants about 45 percent burn more than 1 fuel, the same proportion as for the Nation. In the West, of the 56 utility steam plants in Texas 23 were equipped for oil and gas, the remainder for gas alone; in Oklahoma 13 out of 15 plants were equipped for more than one fuel; in California all 35 plants burn both oil and gas.

The percent of total energy market involved in this situation is impossible to quantify, however. Useful as this information is, it is deficient in that it does not indicate the extent of convertibility in terms of fuel use. For example, in an electric plant listed as being able to use more than one fuel, is the fuel-burning equipment capacity interchangeable? More important is the lack of information regarding nonutility plants, that is, other industrial plants, hospitals, schools, and apartment buildings. Some of these plants have dual equipment but there are no records of the number of installations or the quantity of fuel consumed.

In part of the energy market more than one fuel can technologically provide energy, but some added investment may be required.

As to the future, it is impossible to project economic conditions, consumer preferences, and technology with certainty, but it is certain that technology and taste will change as they have in the past and that these shifts will set up strong pressures for changes in conventional fuel-use patterns.

EXPENDITURES

The economy of the United States rests upon a small base of energy. National income originating in the energy industries is only about 4 percent of the total national income.

Consumers, manufacturers, and government spend but a small proportion of their incomes in the purchase of energy—household consumers about 5½ percent, manufacturers 1½ percent, and government possibly 3 percent. Despite the expanding use of energy these proportions have remained fairly constant.

By households

Household expenditures for energy may be classified as "internal" and "transportation." Internal energy is that used in day-to-day household operations within the physical confines of the home, in the form of gas, electricity, fuel oil, and coal. "Transportation" means private automobiles, and this need is met almost entirely by gasoline.

Surprisingly, however, while energy is so important in today's home, only a relatively small proportion of the consumer's income is devoted to that end. Consumer expenditures for such purposes have risen from $2.5 billion in 1930 to $11.4 billion in 1960, an increase of 360 percent (see table 2). While this represents a great many dollars, it nevertheless amounts to an actual decline in proportion of personal consumer income, from 3.3 percent in 1930 to 2.8 percent in 1960. This reduction is in face of the significant, indeed radical, changes and improvements that have come about in home energy usage over the past 30 years.

TABLE 2. *Expenditures for various forms of household energy*

[Dollars in billions]

Year	Personal income	Internal energy			Transportation, gasoline	Total consumer energy expenditures
		Electricity and gas	Other fuel	Total internal		
1929	$78.9	$1.2	$1.3	$2.5	$1.5	$4.0
1940	78.7	1.5	1.4	2.9	2.1	5.0
1950	227.6	3.1	3.2	6.3	[1]4.9	11.2
1960	402.2	5.0	3.4	11.4	[1]10.6	22.0

[1] Estimates by study group.

NOTE.—Totals may not add due to rounding.

Basic data from Department of Commerce.

Expenditures for electricity and gas alone have risen from $1.2 billion in 1930 to $8 billion in 1960; the percentage of income so represented, however, has risen only from 1.6 percent to 2 percent. These increases are largely due to more intensive usage of household utilities, the consumer having found more jobs for the utilities to do—to air condition, to incinerate, to dry clothes—but in part also because of the switch from coal to gas for house heating.

Expenditures for private automobile transportation in 1960 were about 2.6 percent of personal income, almost the same as the proportion spent for household energy. Spending on gasoline has risen sharply from $1.5 billion in 1930 to $10.6 billion in 1960, reflecting the added dependence of Americans on their family autos, although the portion of income devoted to this end has remained fairly level. Part of the increase is due to taxes and inflation.

All expenditures by the individual consumer, both for household use and for transportation, represented 5.4 percent of his income in 1960, as compared with 5.2 percent in 1930.

By manufacturers

In 1958 manufacturers spent slightly over $5 billion on purchased fuels and electric energy for heat and power, which is substantially less than was spent by households. Figures for earlier periods were $3.3 billion in 1947, $1.3 billion in 1939, and $1.8 billion in 1929. Fuel used for other than fuel purposes and for conversion to other energy forms are not included in these figures. (The years used here differ from those in the section on consumer use because of the availability of different statistical series.)

The Census of Manufacturers' reports show that manufacturing firms spent about 1.5 percent of their revenues in 1958 for fuel and electricity; in 1947 it was 1.9 percent. This proportion ranged from 3 percent to 5 percent in the process industries (chemicals, stone, clay, and glass, and primary metals) down to small fractions of a percent in printing, apparel, and other industries where major proportions of expenditures go to labor and materials.

By the Federal Government

The Federal Government is a substantial user of energy for heating, cooling, and lighting the buildings it occupies, to power its motor fleet, and in other areas. In fiscal 1961, the General Services Administration spent about $7 million for natural gas, oil, coal, and for steam

as such, and $16 million for electricity. The Post Office Department spent an additional $22 million. The General Services Administration, the Post Office Department, and other agencies also lease or rent buildings, the energy requirements for which, while for the use of the Government, get reflected in statistics on the private sector.

Data on purchases of gasoline are too spotty for meaningful summary. The Post Office Department itself spent $13 million for gasoline and motor oils. In 1960 the Federal Government owned more than 213,000 vehicles that used about 214 million gallons of fuel.

In the Government's construction program some of the work is by private concerns so that there, too, energy requirements are in part reflected by the private sector.

A second category of energy use by the Government relates to the Government's role as a supplier of electricity. The steamplants of the Tennessee Valley Authority in 1960 burned 18.6 million tons of coal for which it paid about $83 million, and the TVA operations as a whole supplied Federal agencies with electricity bearing a price tag of $110 million.

A third category of Government energy expenditures relates to the military and atomic energy programs. Military expenditures exceed $1 billion a year for petroleum and its products and $20 million a year for coal, but we have found no figures for outlays for gas and electricity. The Atomic Energy Commisison spent about $232 million for electricity in fiscal year 1961 and an additional but unknown amount for fossil fuels. It was the principal recipient of energy from the Tennessee Valley Authority.

It appears that about 9 percent of the Atomic Energy Commission's total expenditures in 1960, and 1 percent of the Post Office Department's expenditures, was for energy. The figure for the military program, which is less energy intensive than the AEC operation but much more energy intensive than the Post Office operations, would lie somewhere between.

Since the remainder of Government probably falls between the military and the Post Office in terms of intensity of energy use, one may judge that between 1 percent and, say, 3 percent of the Government's operating expenditures are spent for energy.

6. The ultimate grand total of recoverable gas may be in the neighborhood of, say, 1,250 trillion cubic feet. This amount is compounded as follows:

Recoverable from proved parts of known reservoirs: 260 trillion cubic feet.

Recoverable from extensions to present areas and from pools yet to be discovered: Potentially 1,000 trillion cubic feet.

7. How much gas will in fact be discovered and recovered is anybody's guess, depending in part on money invested. The above figures do, however, give some appreciation of future possibilities. Most of the United States is favorable for discovery.

GAS IN COAL SEAMS

Most coal seams contain methane of a quality—1,000 British thermal units a cubit foot—equivalent to natural gas. The gas is contained in the pores and cracks.

Methane is recovered commercially from coal seams in Belgium, Germany, and France, and a little has been recovered and used locally in our own Appalachian area. Gas has always constituted a problem in coal mining, of course, and the mechanization that has taken place in recent years has aggravated it. New faces of coal are exposed so rapidly that the quantity of gas seeping from the coal makes ventilation increasingly difficult and costly, and thought is being given to removing the gas before mining. The Bureau of Mines has experimented on methods of doing this.

A ton of coal (except for the parts above water level or near the surface, from which the gas has leaked out) may contain as much as 2,000 cubic feet of gas. Thus the Appalachian field, which contains some 300 billion tons of coal in place (155 billion tons recoverable; see section on "Coal Reserves"), may contain possibly 600 trillion cubic feet, or twice the current estimates of proved gas reserves. Most of the gas, however, is perhaps so pore-locked as to be released only when the coal is crushed. The imperfect information we have suggests that the average content recoverable without crushing may be no more than 200 cubic feet a ton. At that rate, the potentially usable methane contained as such in the coal seams of the Appalachian region would total 60 trillion cubic feet. For the entire United States the total would be, say, 350 trillion to 400 trillion cubic feet.

COAL

Estimates of the coal reserves of the United States—in the sense of the tonnage that can be mined under existing mining practices and economic conditions and constituting the basis of investment—have been nonexistent.

The U.S. Geological Survey has periodically reported on what it calls the "coal reserves of the United States," but the term is defined as meaning estimated quantities within stated limits of bed thickness and depth below the surface without direct economic connotation. The total figure is said to include the coal in beds 14 inches or more thick to depths 3,000 feet below the surface. The figure is obtained by first estimating the total amount of coal originally in the ground and then reducing this by production to date and by an estimate of

coal lost in mining, to yield an estimate of the coal still remaining. The remainder is divided by 2 to give a figure called "recoverable reserves," this ratio being based on an analysis of a wide variety of studies on individual mines, counties, States, and individual coal seams.

The 50 percent considered recoverable excludes coal left in restricted areas around oil and gas wells and under towns, railroads, roads, and streams, as well as coal left in pillars to support the overlying rock, in thin adjacent seams left unmined here and there, in local areas of complex geologic folding and faulting and thus too costly to mine, coal lost in cleaning, and a small amount of refuse waste. Actual recovery in individual mines has ranged from less than 40 percent to as much as 80 or 90 percent.

The Geological Survey's estimate of recoverable coal, as of January 1, 1960, totals 830 billion tons.[8] The distribution by regions is as follows:

	Millions of tons	Percent of total
Region I of this report, New England (see map)	Trivial	
Region II, Appalachian region	133, 940	16
Region III	90	
Region IV	130, 300	17
Region V, gulf coast	20, 680	2
Region VI (lignite and subbituminous)	347, 580	41
Region VII	83, 070	10
Region VIII, Pacific Southwest	Trivial	
Region IX, Pacific Northwest, including Alaska	79, 300	10

This figure on recoverable reserves has been, and is, quoted as being equivalent to 2,000 years of production at the current rate. The arithematic is faultless but the calculation has little meaning, first because current rates of output are ephemeral, and second, because there is no indication as to how much it would cost to get the coal produced.

Of more immediate importance is the amount of coal available to support immediate and near-term production—the composite national tonnage of coal held by individual producers upon which they have based, or are willing to base, commmercial operations. Of even more immediate concern is the part that has been prepared for mining, the part, that is, into which entries have been driven or equivalent work performed in accordance with a determined mining system and awaiting only introduction of labor and equipment for production to begin. Such information has to be known for each method of mining—strip mining, auger mining, underground mining.

The Department of the Interior[9] reported in 1960 that 20 billion tons would be available at 1958 prices and costs over the next 40 years. As indicated below, this estimate exposes a high degree of expert judgment, but still it does represent judgment alone and does not provide the kind of assured knowledge needed to assess the strengths and weaknesses of the coal industry, particularly its ability to meet a sustained emergency. The necessary information resides only in the files of industry, and the National Coal Policy Conference has circularized the independent coal producers in order to get it for this study.

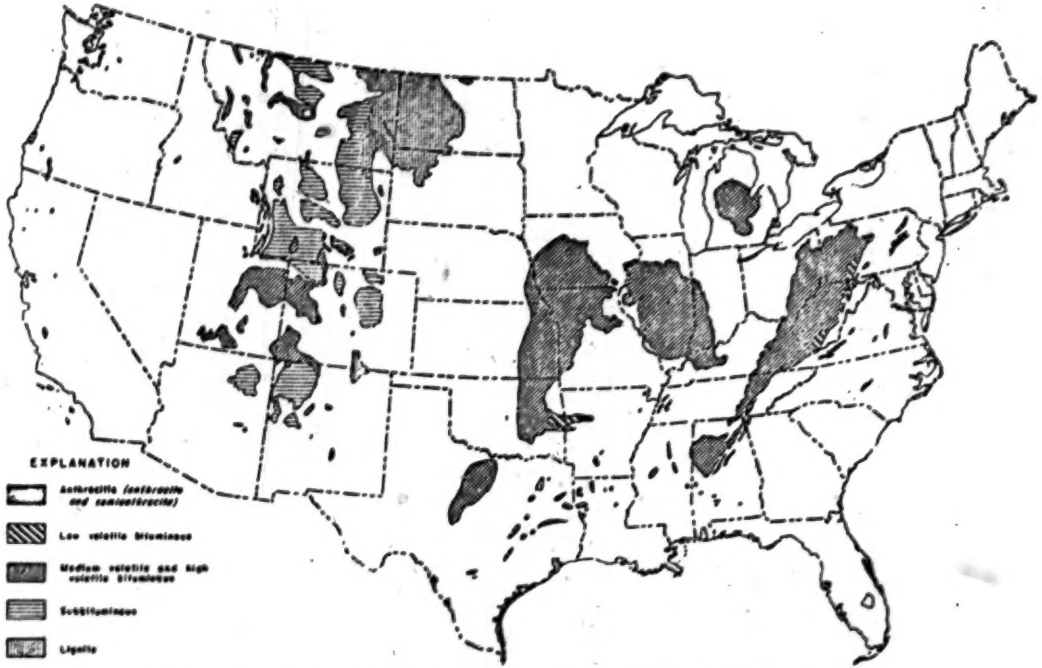

FIGURE 16.—Coal fields of the United States, exclusive of Alaska. Prepared by the Geological Survey, Department of the Interior

Response was received from producers representing, from district to district, 25 to 100 percent of annual output but excluding captive operations. Extrapolating the returns to 100 percent of coverage gives the estimates shown in the accompanying table, with grand totals of 20 billion tons at 1960 prices (of which 3.75 billion tons are strip and auger coal) and 35 billion tons at a price 25 cents a ton higher (of which 5 billion tons are strip and auger coal).

Estimated coal reserves of the United States, 1961

Region	Total reserves				Strip and auger reserves			
	At 1960 prices		At a price 25 cents a ton higher than in 1960		At 1960 prices		At a price 25 cents a ton higher than in 1960	
	Reserves (millions of tons)	Percent of total	Reserves (millions of tons)	Percent of total	Reserves (millions of tons)	Percent of total	Reserves (millions of tons)	Percent of total
II	14,000	70.3	27,000	82.4	2,100	56.0	3,400	68.3
IV	4,000	21.5	5,000	15.2	1,050	27.9	1,200	23.1
V	5	0	5	0	5	.1	5	.1
VI	500	2.7	600	1.8	500	13.2	500	9.8
VII	100	.5	200	.6	100	2.7	100	2.0
IX	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)
Total (rounded)	20,000	100	35,000	100	3,750	100	5,000	100

[1] Not reported.

We often hear the statement that the demands of World War II nearly exhausted the strippable reserves in the Appalachian region. The following table shows a breakdown of the strip and auger reserves in that region.

Reserves of strip and auger coal in the Appalachian region, 1961

	At 1960 prices		At 25 cents above 1960 prices	
	Million tons	Ratio of reserves to 1961 production	Million tons	Ratio of reserves to 1961 production
Pennsylvania, Maryland, northern West Virginia	100	4	300	11
Southern West Virginia, east Kentucky, Tennessee, Alabama	1,300	69	1,700	105
Ohio	200	8	1,100	44
Western Kentucky	300	17	300	17
Total and average	2,100	25	3,400	40

The 4-year and 11-year "life indexes" shown for Pennsylvania, Maryland, and northern West Virginia, which are the States whose strip and auger mines have been feeding fuel into the Eastern States, have no significance, however, as to whether reserves are running out or not. We have no past estimates of reserves against which to compare them in order to see if a short life index is a characteristic of that part of the coal industry or, if on the contrary, the index has been progressively decreasing as an indication of approaching ex-

haustion. We can be certain that continued improvement in coal mining technology and productivity (see chapter on "Technology") will have made most or all of the additional 200 million tons minable, at prices equivalent to those of the present, well before the 4-year quantity runs out, and will have made minable also several hundred million additional tons at a then moderate increase in price. At about 1965, then, reserves of surface coal in the northern Appalachian region, minable at 25 cents above the then price, should be some 500 million tons, with additional tonnages made available if improving technology can make possible the stripping of thicker overburden or deeper extraction with augers.

In any event, any possible exhaustion of strip reserves in the northern Appalachian region might be made up from nearby producing areas. The significance of strip reserves is not that they have any special quality, but (*a*) that in general they yield lower cost coal than underground reserves and (*b*) that output from surface mines can be expanded, in an emergency, faster than from underground mines.

FISSIONABLE MATERIALS

The Atomic Energy Commission has reported to the President that reserves of uranium in the United States in June 1962 were 175,000 tons of U_3O_8 minable at the price of $8 a pound. A "significant but undeterminable" additional tonnage would become available at $20 a pound, and perhaps as much as 5 million tons would be available at $50 a pound. These figures compare with a 1961 U.S. production of 18,000 tons U_3O_8 and a total 1961 Free-World production of 36,000 tons.

The amount of applicable energy that these reserves represent depends on the efficiency of the atomic reactors in which they may be used. (See section on technology.) The 175,000 tons of reserves mentioned above could be the equivalent of as little as 10 billion tons of coal or as much as 500 billions tons.[11] That is, as raw energy material $16,000 worth of U_3O_8 (1 ton) is the equivalent of at least $200,000 worth of coal (some 40,000 tons at average U.S. mine price of $4.85 a ton). The 5 million tons of U_3O_8 available at a higher price are equivalent to between 200 billion tons and 10,000 billion tons of coal. The figures are hard to grasp; perhaps they can be brought into perspective by noting that the minimum figure of 10 billion tons of coal equivalent is more than the amount of coal used in the United States in the past 20 years, whereas the top amount is six times as much as all the huge coal resources of the country. (See preceding chapter on coal resources.)

Additional quantities of U_3O_8 could be found if sought, and there are also quantities of thorium ore. Considering the magnitude of the above figures, however, for the purpose of this report there is no need to speculate on how much additional U_3O_8 could in fact be found, or to be concerned about the actual figures on thorium.

A related speculation comes to mind, namely, whether the money and effort that would be needed to find more uranium might better be spent in improving reactor efficiency, but the speculation tends to answer itself. Human nature being what it is, improvement in reactor

[11] Joint Committee on Atomic Energy, Robert McKinney, p. 38.

LABOR

COAL

The labor used in coal mining ranges from the unskilled to the highly skilled. Five States—West Virginia, Pennsylvania, Oklahoma, Illinois and Arkansas—have requirements regarding apprenticeship. In those States no man can be employed in a responsible mining job until he has a miner's certificate, obtainable after a year of employment, and has taken an examination. Pennsylvania requires 2 years of training for anthracite miner, and requires a certificate for anyone who handles explosives, underground or surface. In addition to the skilled miner, there are also the trained maintenance workers and supervisors. Labor supply in coal production, then, covers both quantity and quality or occupational composition.

There are three continuing official sets of statistics regarding coal mine labor: (1) by the Bureau of Labor Statistics; (2) by the Bureau of Mines; and (3) by the Bureau of Employment Security. The Bureau of Labor Statistics' figures are based on payroll information and cover both all employees and, separately, production and related workers through the working foreman level. The Bureau of Mines' figures are gathered in connection with the Bureau's mine-accident interests and do not cover store and office workers. The figures of the Bureau of Employment Security are compiled in connection with unemployment insurance laws and cover everyone on the payroll including top management but excluding the self-employed and officials of unincorporated firms. The first two tabulations are not clear as to the extent to which they include working proprietors. There are about 5,000 mines employing less than 10 men each and in which, presumably, the owner himself works. The three series differ one from the other in a way not always related to coverage; for example, in 1959 the Bureau of Mines' figures were 11,000 larger (7 percent) than the broader ranging Bureau of Labor Statistics' figures.

According to the Bureau of Mines, the average number of employees in bituminous coal mining in 1960 totaled 169,400. This is the lowest number for 70 years at least. (See fig. 36.) Of this total 84 percent were employed at underground operations, 15 percent in strip mining, and 1 percent in auger mining. Regionally, 86 percent worked in region II of this report (the Appalachian field), 9 percent in region IV (the Midwest coal field), 3 percent in region VII, and less than 1 percent the other regions.

The average number of men employed in anthracite mining in 1960 was 19,051, all of them in Pennsylvania. Eight-tenths were employed at underground operations and two-tenths in strip mining.

The total coal mine labor force is thus about 0.3 of 1 percent of the total U.S. labor force.

Three-fourths of the coal labor force, bituminous and anthracite combined, is union-affiliated, one-fourth nonunion.

Fewer and fewer young men are applying for miner's certificates, and as a result the average age of coal miners has been rising—estimated from 40 in 1951 to 45 in 1960.

There is also a substantial number of unemployed miners. In a survey made for this study by the bituminous coal industry, it was reported that during June 1961, in the seven ranking coal States plus

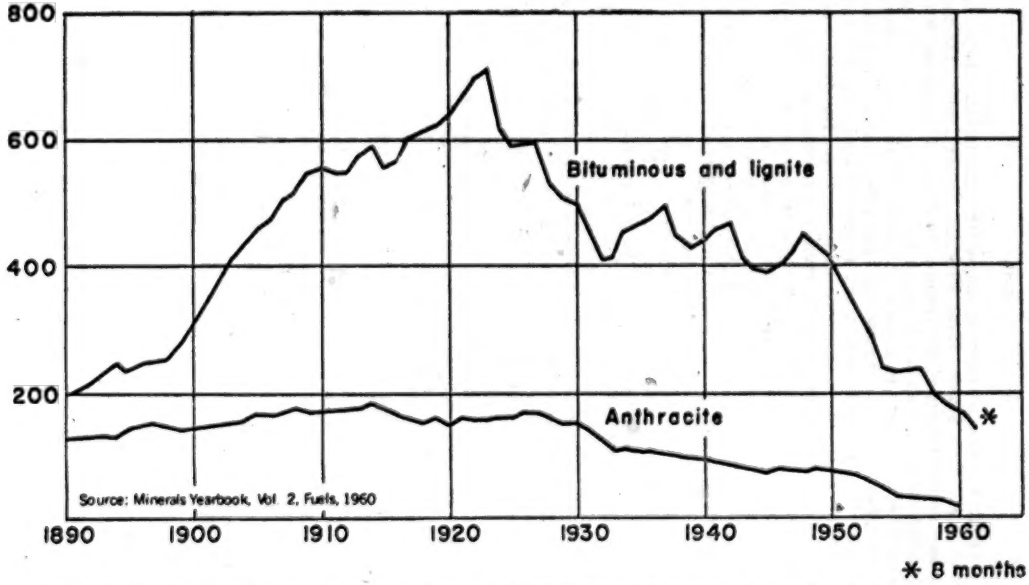

FIGURE 36.—Number of men employed in coal mining in the United States has been decreasing since the twenties, 1890–1960.

Tennessee (which eight States account for about 90 percent of U.S. production), there were 129,530 men employed and 32,760 unemployed, for a total labor availability of 162,290 in those eight States. (These figures include production workers and shopmen—i.e., hoistmen, carpenters, machinists, electricians, and the like.) There is an additional number of unemployed who do not appear on unemployment rolls and for whom, therefore, the reporting agencies had no record.

No parallel figures are available relating to the other coal-producing States, but the State coal associations in six of them, including the Western States, report an excess of available underground labor. A few having strip-mining operations reported also an excess of strip-mining employees, and a few reported surplus auger mining employees.

The United Mine Workers of America estimate that throughout the country unemployed coal miners (bituminous and anthracite) number 100,000.

In addition to the production workers and shopmen, a substantial number of persons are employed in professional capacities (surveyors, accountants, lawyers, and the like) and on the clerical and sales forces. According to some 1950 figures from the Bureau of the Census—the latest presently (February 1962) available in this regard—these may total an additional 10 to 15 percent, or some 15,000 to 25,000 persons.

Very little information is available as to the skills of those employed. The 1950 census figures give a detailed breakdown among the shopworkers but make no useful breakdown as to production skills required in operating complex mining machinery and in mine maintenance.

Although there appears now to be about 25 percent more labor than is being used, it does not follow that this 25 percent is usable. We do not know where their skills lie. If, for example, expanded production should be called for from strip mines, it may be found that there is a shortage of dragline or shovel operators; if the expanded production is attempted from underground mines, there may turn out to be a shortage of men who can operate a mechanical loader, a continuous mining or cutting machine, or who know how to put in roof bolts or to lay track.

One may assume that the unemployed workers represent all the skills involved, and in representative proportions, but the assumption is not necessarily a safe one.

Opinions from coal people vary from 1 week to 3 years as the time necessary to train a person adequately to do an underground job. The extreme range in time is due both to difference of opinion and to the nature of the job, but most coal people believe that after the year necessary to obtain a miner's certificate (2 years in anthracite mining) the average person could perform any assigned production job. Training for a supervisory capacity or for maintenance work on complex machinery takes longer. On the other hand, a man who can operate a dragline ought in short order to be able to operate a coal cutter or any other piece of equipment; the average mechanic should not need much training to be able to repair complex mining machinery. Admittedly, it may take a little extra time for a person to be-

come alert to safety factors, such as the character of the roof or t possible presence of gas.

Relation to markets and productivity

Two factors have influenced the decline in the labor force sho in figure 36: (1) less production and (2) increased output per wor (See chapter on productivity.)

Production of bituminous coal and lignite was 27 percent less 1960 than it was in the year of peak employment, 1923; assumi no change in efficiency of production the 1960 output would t have taken 27 percent fewer men, or 190,000 less than in 1923. T is the reduction in the labor force that may be attributed to smal output. The 345,000 remainder of the total reduction of roug 535,000 men (704,800 to 169,400) would be the part attributable increased output per man.

The vigorous efforts of the bituminus coal industry to improve t output per man reflects the intention to keep the cost of producti under control. In 1960, wages at $3.15 an hour were higher than any other American industry; the next highest were in petrole refining, at $3.02 an hour.* Despite the fact that bituminous co miners worked on average a smaller part of the week than other labo weekly earnings also were near the top.

In anthracite mining increasing output per man has been less a factor. The peak year of employment was in 1914. Producti in 1960 is 79 percent less than in that year. Again, had efficiency production remained constant, 1960 production would have requir 79 percent, or about 140,000, fewer men. The total decline in e ployment has been about 160,000, meaning that in anthracite minin employment has gone down about 20,000 because of improved outp per man, and 140,000 because of reduced market.

OIL, GAS, AND ELECTRIC UTILITIES

Gas pipeline companies and electric and gas utilities have deve oped comprehensive employment information, largely because of t stringent reporting requirements imposed on regulated industrie For petroleum, the information is less complete.

The following table shows 1960 figures:

	Employees	Percent of U.S. labor force
Petroleum and natural gas productions	283,000	0.
Petroleum refining	182,000	.
Gas pipelines and distribution	206,000	.
Electric utilities	340,000	.
Total	1,011,000	

Source: Bureau of Labor Statistics, *Earnings and Unemployment*, February 1961.

The 470,000 employees shown in petroleum and natural gas pr duction and in refining do not include those engaged in various phas

* U.S. Dept. of Labor Monthly Review, March 1962.

The economic advantages in the concept of "transporting coal by wire"—the burning of the coal in utility plants located at or near the mine and then moving the electricity to the point of use—lies in the fact that the average utility plant has to transport about 10,500 B.t.u.'s in the form of coal to generate only 3,400 usable B.t.u.'s in the form of electric energy, as explained in the chapter on "Technology."

CONCLUSIONS

The preceding pages on transportation contain largely descriptive material that speaks for itself for the moment and that will take on major meaning only when brought together with other material in comparing the demand for energy with the supply available (pt. VI of this report) or in discussing specific policy issues (pt. VIII). A few conclusions emerge, however, that are of direct policy relevance.

1. Except for a small amount used in the process of production, all energy, of whatever kind—coal, gas, oil and its products, or electricity—has to be transported from point of origin or production to point of use.

2. Although there has been a general downward trend in the tonnage of coal shipped by rail over the past decade and a half, and a steady decline in the percentage of coal shipped by rail, revenues from coal traffic have stayed firm as a result of adjustments in freight rates.

3. The ratemaking system used by the railroads permits adjustments in some circumstances to allow coal to be marketed at a price that can compete with oil or gas at the same destination. The cost of producing coal—a nontransportation factor outside the control of the railroads—is thus a factor in railroad freight rates.

4. The ratemaking system used by the railroads considers also the ability of different mines in the same general region to compete in common markets, and thus takes coal-mining costs into account to a still further degree. Differential adjustment has aspects of preferential adjustment.

5. On a U.S. average, railroad freight charges for at least 20 years have constituted more than four-tenths of the delivered price of coal.

6. The shortage of cars to move coal, complained about from time to time in the Appalachian and midwestern coal regions, is the result of business decision on the part of the railroads. The railroads repair damaged cars only as traffic demands it, and a shortage results when business pickup moves faster than the ability to repair the cars.

7. Whether or not such car shortages as there have been have impaired the total supply of coal to the country, or have caused users to turn to competing fuels, is a matter of opinion—there are no statistics or other documented information on the subject.

8. While in peacetime barge transportation along the waterways of the country is simply a competitive form of movement, truck haulage is a necessary part of the transportation systems for coal and oil.

9. The low direct operating cost of pipeline transportation, and its ability to deliver a product continuously, is directing attention to the pipeline transportation of coal as a competitor of railroad transportation. This development could materially influence the market outlook for coal, but its ultimate success will depend not only on pipeline technology but also on railroad technology and rates and on the political problem of eminent domain for right-of-way.

10. The economics of transporting electricity and natural gas are similar in that each must arrange to meet high peak requirements, both daily and seasonally.

EMERGENCY

We are dealing in this chapter with the same attempt at before-the-fact interpretation as in the chapter on emergency requirements. Despite the fact that the problem of emergency transportation has been under scrutiny since 1947, information on it is scanty and in some instances conflicting, and the President has directed the Secretary of Commerce (by Executive Order 10999 of February 16, 1962) to come to grips with it. The paragraphs that follow should be read within these qualifications.

COAL

The emergency transportation of coal poses a problem that other forms of energy do not, in that it competes with other bulk commodities that also use open-top cars, barges, and trucks: ores of urgently needed metals, sand and gravel for concrete and other construction, and crushed stone also for concrete aggregate, for railroad ballast and highway construction, and in smelting and other industrial processes. Information on emergency demand for these other items is lacking. A second lack is information on how much unused capacity is available for emergencies.

Heavy loss of rolling stock and facilities in prime *nuclear* target areas can be expected, but a large number of classification yards, truck terminals, and inland water terminals are in target areas of low priority—according to American transportation experts' version of the enemy's plans. Yet an attack may well be preceded by a well-timed wave of sabotage, and inasmuch as transportation is always a key focus of enemy attention, damage may be greater than suggested above. In any event, transportation equipment by its nature is always widely dispersed, and only a relatively small number of pieces will be in any presumed target area at any one time. The overall capability of the railroads, bargelines, and truck fleets is thus expected to survive a nuclear attack better than the consuming, oil refinery, and electric-generating segments of the economy. Even assuming heavy loss of rolling stock and facilities in target areas, the movement of the reduced requirement could be met, it is expected, with surviving equipment and facilities through reduction of turnaround time, alternate routings, and other measures all of which are routine in the transportation industry, such as close coordination of rail, motor, and water movements, "piggyback" operations, and cannibalizing damaged facilities and equipment. Equipment and rolling stock from the construction and ore-mining industries, both of which would be shut down for some months following an attack, could be utilized.

Locomotives offer reasonably good shielding against fallout, and tests suggest that trains should be able to travel anywhere soon after an attack. The tests suggest also that, except in areas of most lethal fallout, maintenance and repair crews could enter facilities like classification yards and repair shops within a matter of weeks.

Coal movement through the Great Lakes and by the inland waterways would be crippled if navigation locks and bulk handling facilities

nonreactive to the waste solutions; (3) to pump them into exhausted oil sands or other deep permeable formations; (4) to dump them far out at sea or on the polar icecaps; and (5) to package and shoot them into outer space. Serious obstacles are inherent in each of these. For example, in pumping into geologic formations, the chemical reaction between the waste solutions and the environment is likely to be such that the pore spaces may become quickly clogged and the whole operation brought to a halt. Disposal at sea is faced with a grand ignorance about ocean currents and the ecology of marine life.

The National Academy of Sciences has had a panel working sporadically on these problems since 1954. Research on matters of this kind moves slowly, and no one would dare predict when the problem of waste disposal will be solved. One point of view is that before the problem becomes crucial an isotope technology will have developed that will require all the Sr^{90} and Cs^{137} produced.

Corporate Concentration

In tune with industrial development throughout the country, a relatively small number of coal, oil, and gas companies account for most of the production. In logic and by analogy with other mineral industries, a few companies probably also employ the bulk of the labor, although because of mechanization in the large coal operations and because large operations are generally the more efficient, the concentration of labor is not so great as is concentration of production. If statistics are available on this subject, they are widely distributed and not readily obtainable. It is probably true also that the companies that produce the most own most of the reserves as well, but only speculative figures on reserves of coal, oil or gas company by company are available.

A similar corporate concentration exists in the electric generating industry. Electric power is generated relatively close to where it is needed—or in the case of hydropower, where good sites exists—and is used within a limited radius where it is generated, so that the corporate concentration that exists is related more to population and industrial concentration and to facts of Nature than, as in coal, oil and gas, to business decision.

Yet, while there is this corporate concentration in the energy industries, these industries are not as concentrated as many other industrial segments in America. Notable examples are the automobile, tire-manufacturing, gypsum-products, aluminum, steel, and acid-manufacturing industries, in which no more than four companies account for eight-tenths or more of shipments.

COAL

The 5 ranking coal companies in 1960, out of a total of roundly 7,500 (0.07 percent), produced almost an even fourth of the year's total output. The top 10 companies produced an even third, and the top 25 produced half. The other half was produced by the remaining 7,400 and more. See figure 64.

Some coal operations are captive, i.e., the mining companies are owned by steel companies and public utility systems and produce coal

for the parent company as needed. If these operations are excluded, the concentration is a little less acute.

The concentration by company is paralleled by a concentration in mines. Small operations have been and are being combined into large ones, inefficient small mines get shut down, and efficient mines are enlarged. Despite this, the total number of mines in operation has generally increased. Figure 65 compares the situation in 1960 with that in 1910 when coal production was on the way up and total output was the same as in 1960, at 416 million tons. Although there were a third fewer mines at that time, they were more uniform in size. Thus while 10 percent of the mines yielded 44 percent of the year's output in 1910, in 1960 this output was provided by only 4 percent of the mines. Or while 10 percent of the mines in 1910 yielded 44 percent of the output, 10 percent in 1960 yielded fully 80 percent of the output.

We do not have full information for the individual coal-producing regions. The bit that is available indicates that the national averages obscure some important regional differences. Nationally, mines producing less than 50,000 tons a year each constituted, in 1960, 80 percent of the firms but contributed only 16 percent of output. But mines of that size produced fully 56 percent of the tonnage in Tennessee, 47 percent in Virginia, and 35 percent in eastern Kentucky.

OIL

In crude oil production (again see fig. 64) a fourth of the output (1959) is by the five ranking companies. The top 10 companies produced 37 percent, and the top 15 companies 44 percent.

In refinery operations four-tenths of the output (1959) is by the first five companies. The top 10 companies produced more than six-tenths, and the top 15 companies three-fourths.

GAS

Because of the large investment required, few companies can afford to get into the gas transmission business. Moreover, the economics of scale favors large firms. As a consequence, corporate concentration is high, the highest, in fact, among this group of industries, 15 companies out of 106 (14 percent) in 1960 accounting for 84 percent of the industry's total gas sales. In gas distribution, in contrast, 84 companies (out of 1,324) accounted for this same 84 percent of the sales.

The only figures available on corporate concentration in gas production are for 1954. According to them, and by strange coincidence, concentration in this industry—as measured by number of firms and percent of output or sales—is almost precisely the same as in the gas distribution industry. Gas distribution is much the more concentrated of the two as measured by percentage of firms.

ELECTRIC GENERATION

Concentration among companies and systems generating electricity closely parallels, up to about half of total output, corporate concentration in gas distribution and crude oil production. The top 5 companies or integrated systems account for nearly a fourth (23 percent in 1960)

FIGURE 64.—A relatively few companies account for the bulk of output and sales in American energy industries.

of the kilowatt-hours sold, and the top 20 account for more than half (53 percent).

These statistics cover all kinds of companies and systems—privately owned, publicly owned, and cooperatively owned. The two largest systems in the country are TVA and Bonneville, which together in 1960 accounted for exactly one-eighth of all the electric power used.

Table 24 assists the chart in bringing the statistics into comparative focus.

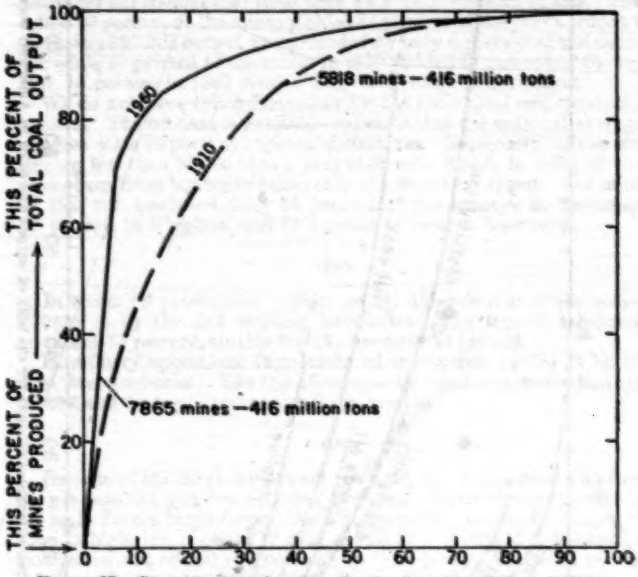

FIGURE 65.—Concentration of coal production by mines, 1960 and 1910.

TABLE 24.—*Corporate concentration among energy industries in the United States*

Number of firms	Percent of total sales			Total firms
	8	13	20	
Gas transmission	39.9	54.2	66.1	108.
Oil refining	30.4	73.1	87.2	172.
Gas distribution	23.4	48.6	65.8	1,274.
Gas production	23.0	47.0	59.0	About 11,000.
Electric generation	23.2	45.7	58.7	3,600.
Crude oil production	23.0	44.3	62.5	About 11,000.
Coal production	24.5	39.5	48.0	1,112.[1]

[1] Producing 100 tons or more a day. Total number of companies is 7,300.

CONCLUSIONS

1. Far fewer firms account for the bulk of output or sales in gas transportation and oil refining than in electric generation, gas distribution, crude oil and natural gas production, and coal mining, which four are much alike in this respect.

2. The coal industry is the least concentrated of all, gas pipelines the most concentrated.

3. The compass of greatest concentration in each of the several industries is roughly as shown below. This indicates generally the break, as read from figure 64, between, on the one hand, the few large producers who account for the bulk of output and on the other hand the relatively—in some instances absolutely—large number of firms who account for the small remainder.

	Number	Percent of output
Gas transmission	Up to 11 out of 106 companies	75
Oil refining	16 out of 172	74
Gas distribution	11 out of 1,204	60
Gas production	11 out of about 11,000	60
Electric generation	11 out of 3,600	60
Crude oil	8 out of about 11,000	60
Coal	6 out of 7,000	32
Coal, nonsaptive	11 out of 7,000	32
		34

MARKETING AND PRICING PATTERNS

COAL

The marketing of coal may be said to begin with the mining itself. This is true because the mining methods employed may so affect the product as to determine to some extent the ultimate market. For example, high-speed mechanical mining machines tend to yield a high percentage of fine or slack coal (small sizes) that cannot be sold in the markets for lump or larger size coals. Mining of the full seam, as is often done, taking the bands of impurities along with the coal, may require that elaborate cleaning equipment be installed in order to make a marketable product. In reverse, the market may influence the choice of mining methods, as for example, in the selective mining that is sometimes used in order to get the quality of coal for making coke.

Marketing

Coal is sold in the following ways:

(1) By a producing company's own sales departments.

(2) By a sales organization owned either by the producing company or by a group of producers.

(3) By a sales company that owns or otherwise controls directly or indirectly, the producing company.

(4) By the sales department of another producing company.

(5) By a broker or independent sales organization who acts as agent for a producing company under contract or who may purchase for resale.

(6) By a captive mine directly to the owner's consuming plants.

An individual company generally relies on a single method in selling most of its output but uses a variety of methods in effecting total sales.

Only a relatively few producing companies are large enough to afford a sales department or an affiliated sales company. Most find it more economical to use the services of independent sales organizations, which provide for a group of small producers the same services provided by the sales department or sales affiliate of a large integrated company.

Consumers who have a railroad siding and are able to receive at least a full carload of coal, and those who are located on navigable waterways, purchase directly from the mine's representatives. Consumers who do not have such facilities usually purchase coal from a retail coal merchant. This had led to a general categorization of customers as either "on-track" or "off-track" accounts. There is also an ever-increasing volume of coal moving by truck and barge directly from mine to consumer. In recent years, some consumers have located plants adjacent to coal mines where coal can be delivered by belt conveyor or by other suitable means direct to the consumer's plant. There are other special situations, such as the coal pipeline in Ohio, but these are not now a part of the general marketing pattern.

The retail market includes, aside from a relatively few home users, some industrial users and such other users as hospitals, apartment houses, schools, and office buildings, where coal-burning equipment requires the smaller sizes of coal. In 1960, less than 10 percent of the total bituminous coal and 70 percent of the anthracite consumed in the United States was classified as retail deliveries.

The patterns of coal usage, competition, and transportation charges vary among coal-producing areas and tend to create a geographic marketing pattern. Thus, coal produced in Pennsylvania, Maryland, and northern West Virginia is marketed primarily in the northeastern part of the United States (New England and Middle Atlantic States, including Maryland and the District of Columbia), whereas coal produced in southern West Virginia, Virginia, and Kentucky is marketed to a large extent in the Midwest, in the area around the Great Lakes, and to tidewater for export.

Figure 66 shows the amount of coal sold to electric utilities and the percent of the total utility shipments, by regions, for 1957 and 1960. The year 1957 was selected for comparison because that is the beginning of the statistical series applicable to this chapter and amenable to the regional breakdown we are using. The figures for regions V to IX are grouped in one total. Figure 67 shows the distribution of coal sold through retail dealers, figure 68 the coal sold to coke and gasmaking plants (only a few gas plants are still operating), and figure 69 to "all others," which category includes mainly industrial users.

Pricing

Originally all coal was sold as it came out of the mine and was called run-of-mine coal. The primary use was for heating purposes. Customer dissatisfaction with the fine or slack coal and with the fragments of rock and other impurities contained in the run-of-mine product led to the first crude forms of preparation, such as picking out the fragments of rock by hand and sizing by use of makeshift screens. The fine coal passing through the screens was usually poorer in quality than the run-of-mine and larger sizes of coal, and there was a limited demand for it. As a result, the larger or prepared sizes were priced higher than run-of-mine coal while the fine sizes were priced lower, in order to maintain an average realization as nearly equal as possible to the run-of-mine price. The introduction of costly preparation facilities at the mine led to an even greater number of size designations, each carrying a different price.

The larger sizes were sold in substantially smaller tonnages than slack sizes, with the result that the cost of marketing was considerably higher. This made it necessary to widen further the price spread between the larger sizes, such as lump and egg coal, and the finer sizes of slack. As the market for larger sizes of bituminous coal declined—railroads, home heating, and some industrial plants—many mines serving this market had to crush their coal to the smaller sizes needed by the utility and general industrial markets. A substantial part of this market was demanding more precise sizing and cleaning, and all told there may have been hundreds of combinations of sizes and qualities.

Logically there could have been a substantial increase in the price of coal to utility and general industrial markets—which by then had developed into the industry's principal source of revenue—but this was impossible because of the competition developing from residual oil, natural gas, and hydropower. Thus the price pattern that had developed under one set of market conditions persisted even after those conditions had changed.

A special pricing situation developed in connection with coal for metallurgical use. The steel industry requires coals of special quality for the production of coke. As the steel industry grew, this requirement led to the opening of mines to produce coal for that particular use. High-quality coking coal commands a higher price than other coal of equivalent sizing. But steel is a cyclical industry, and in order to keep the mines in operation and to minimize losses during periods of low steel production, the coking-quality coal is sometimes directed into the general industrial market where it must meet the price of the coal normally servicing that market.

Some mines are opened and equipped for the specific purpose of supplying electric generating plants. Many of these electric plants are willing to take run-of-mine coal, doing their own crushing. The avoidance of preparation at the mine makes it possible to quote lower prices to the utility companies able to use coal in this manner. This practice, in turn, has forced mines having elaborate preparation capacity, that was developed under different marketing conditions, to reduce their prices in order to meet the competition.

Coal is sold by three basic methods: Spot orders, annual contracts, and long-term contracts. Spot orders usually specify delivery within

30 days, although occasionally the time is extended. Annual contracts, as the term implies, provide for the delivery of coal over a period of 12 months; while usually for specific tonnages, occasionally they specify maximum and minimum allowances. Long-term contracts are generally written for periods of 5 or 10 years, although some run as long as 20 years. They often call for the entire output of a mine. No information is available on the tonnage of coal sold under contracts of various duration.

Contracts allow the mine operator to receive a stated price for his production and may allow him to benefit from increased production efficiency during the term of the contract. Long-term contracts normally have escalation clauses, usually quite elaborate, that provide for price adjustments as a result of increased labor and supply costs. They also have cancellation clauses.

Regardless of price or of the way the coal is sold, the price to the consumer or retailer is usually f.o.b. the mine. Exceptions to this general rule are when coal is sold to commercial dock operators on the Great Lakes or at tidewater for export. The price f.o.b. mine for a particular class of coal is not, however, always the same, adjustments sometimes being made to offset freight charges in some degree in order to meet competition.

An appreciable amount is sold on the basis of B.t.u.'s delivered to the purchaser's plant. Government purchases generally embody penalty clauses by which the supplier receives less per ton for his coal if the B.t.u. value or other quality drops below that guaranteed in the bid; Tennessee Valley Authority contracts include both premium and penalty clauses, as do also some commercial contracts.

The bituminous coal industry does not post formal price quotations. The Bureau of Mines publishes statistics on average price of coal sold, f.o.b. mine, making a distinction between coal sold in the "open market" and coal "not sold in open market." The latter category refers to production by mines owned by or affiliated with the consumers. The Bureau of Labor Statistics publishes figures on wholesale prices. The figures published by the Federal Power Commission are delivered prices to steam electric plants, reflecting, therefore, from year to year not only changes in the f.o.b. mine prices but also changes in the source of supply, method of transportation, and freight rates.

CRUDE OIL

As described for coal, the marketing of which begins with the mining operation itself, the marketing of crude oil spans the entire territory from the wellhead to the refinery.

The movement from field to refinery is discussed in detail in the chapter on transportation, but a few features that affect marketing practice are repeated here. The large trunk pipelines for the most part are owned by the large integrated companies and are common carriers subject to regulation by the ICC. The gathering lines that connect individual producing leases to the trunklines also are owned generally by the pipeline companies, but some are owned by the producers themselves. When a well is brought into production, its operator understandably seeks to market the oil by selling it to someone who can provide a pipeline connection.

PART IV—INTERFUEL COMPETITION

Introduction

Competition among fuels is a complex of economic, technologic, and political forces. The three fuels—coal, oil, and gas—compete with one another for the electric energy, space heating, and process-heat markets; electric energy (including hydropower) then competes with coal, oil, and gas for parts of these same markets. The subject is complex technologically because of the many areas in which it operates, as described in the chapter on technology: production, conversion of the raw fuels to energy, transportation, and use. As technology changes, so do costs and competitive relationships. The joint techno-logic-economic complexity is compounded by atomic energy. The subject is politically complex because it is involved with problems of trade, utility and transportation regulation, conservation, public versus private power, and such social problems as unemployment and public fears regarding disposal of atomic wastes.

The present chapter attempts to untangle some of this complexity. As indicated in a preceding chapter (Part I: Energy in the Economy), part of the market held by each of the fuels is noncompetitive with other fuels. The following pages deal only with the interfuel competitive aspects.

Historical Perspective

Prior to the Civil War, wood was the dominant fuel in this country, both for home heating and as industrial fuel; more than half of all iron produced, for example, was smelted with charcoal. (See figs. 1 and 90.)

When coal began to displace wood, it did so as a unique energy source that provided services wood could not. Its flame was found to be more adaptable and controllable; its energy was found to be more concentrated, so that it was more easily and cheaply transported; it could be handled more readily than wood logs or charcoal; and it was available in quantities that wood could never achieve. It invited new and expanded uses. Between 1850 and 1890, consumption roughly doubled every decade, largely the result of increasing use as a metallurgical and locomotive fuel. Then after 1900 came the rapid growth of the electric power industry. None of these markets could have developed with wood. Coal dominates the electric generating market to this day.

Coal reached the peak of its growing share of the energy market in 1910, having yielded to a new fuel—oil—unique and necessary to the time in the same way that wood did when it yielded to coal. Oil initially had a small use for illumination, but after 1900 it began to be used more and more by railroads and naval vessels. Just as coal had formed a long-lasting union with electric generation, oil formed a long-lasting union with transportation. The demand for motor

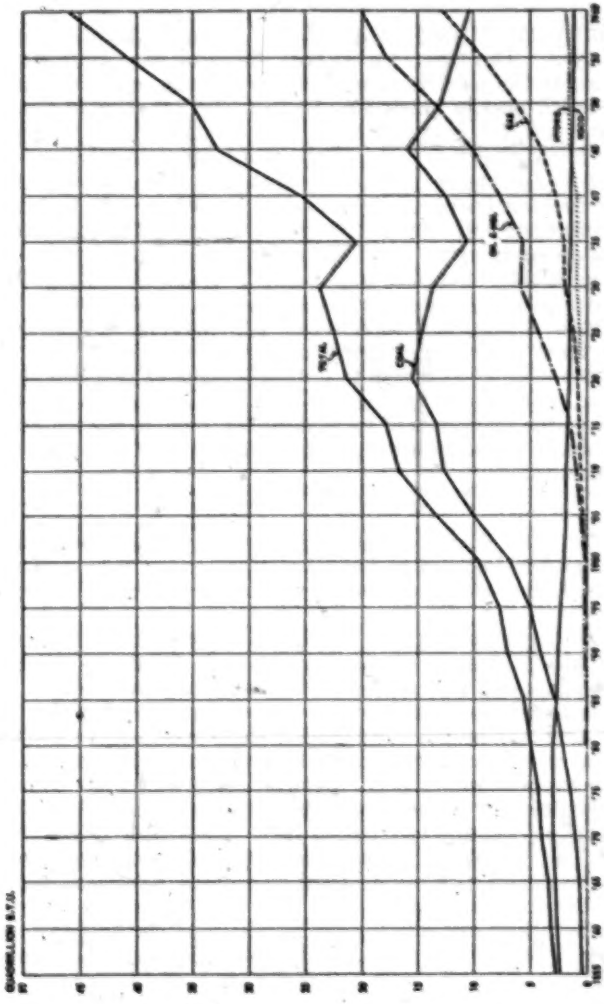

FIGURE 90.—Trends of competitive consumption of primary energy in the United States.

Source: 1855–1955 after Schurr and Netschert, "Energy in the American Economy, 1850–1975," pp. 511–513; 1960 Bureau of Mines final summary.

fuels increased sixfold in the period from 1925 to 1955. Concurrently, oil was invading other coal markets as well, and by 1940 had preempted a great deal of the home heating market. The net result has been a decline in coal consumption that, except for an interruption during World War II, has persisted to the present. The two peak periods, 1918 and 1943–44, were war years.

Oil in its turn—and coal, too—has had to face up to gas, as unique with respect to oil and coal as oil was with respect to coal, and coal to wood. Gas became competitively active on a national scale as soon as there was developed a technology of constructing high-pressure, long-distance pipelines to carry it to a waiting market. In 1945 only about 1 trillion cubic feet of natural gas entered interstate commerce. By the mid-1950's, this volume had increased fivefold; by 1960, eightfold. Gas displaced coal in a number of industrial uses, and coal and oil in space heating—a market that had been previously claimed by wood, coal, and oil in turn. The movement of gas into this market has been one of the major factors slowing the growth of oil consumption.

Table 1 in part I suggests the end-use patterns presently in existence. The table shows the pattern in detail as it was in 1955, which is the latest year for which this breakdown has been published, together with the totals for 1961. The cycle is not ended, for electricity is making inroads into the gas-residential market.

Influencing Factors

Competition among products serving a common market can be defined as the pattern of effort among the producers of those products to secure the favor of the customer by offering to meet his wants on the most favorable terms. The quantities used represent the result of those efforts. In other words, competition results from the ability and willingness of the customer to shift from one product or supplier to another. When, in an economic sense, consumers of fuel are able to shift freely from one fuel to another, there is intense competition among the fuels, and the degree of competition intensifies and softens as this freedom of choice expands or contracts.

Many factors influence this freedom of choice. In part of the energy market, the consumer has equipment that enables him to switch at will from one fuel—coal, oil, or gas—to another; freedom of choice is wide, and competition is keen. In other parts of the market, more than one of the fuels could serve the purpose, but some added investment in the way of new equipment may be needed; the economic choice is less free and competition accordingly less keen. In still other parts of the market, one fuel may satisfy the consumer's wants in a way that no other fuel can, in which case he really has no practical choice, except as to which supplier he selects.

Where more than one fuel may be used, the choice is approached initially on the basis of cost. Other factors are convenience and simple preference, and particularly reliability of supply. However cheap a fuel may be, it may not be selected if the user cannot be certain, within the dictates of his needs, that he can get it in any quantity he wants whenever he wants it and at a price he can afford. There are also political factors, which may circumscribe all the others and that operate in a manner not always immediately obvious. At any partic-

ular time, Congress or other authorized public institution may determine that the public welfare requires some interference with market economics, in which case a whole chain of consequences may ensue.

The situation at any given time represents an economic equilibrium, but the equilibrium is both fragile and fleeting.

Each of the several factors is discussed under appropriate headings in the following pages, to the degree necessary to open the way to a discussion of competition in the individual market areas. Many are intimately related, and the limits of discussion are in a sense arbitrary. The point of much that is said has already been made and documented explicitly in earlier chapters.

THE PHYSICAL CHARACTER OF FUELS

The historical development of the use of fuels is based in good part on their physical character. As already noted, one reason coal replaced wood is because the energy in it is more physically concentrated; as a result, the flame is more controllable, and small hunks of this concentrated energy can be handled more easily than one can handle logs of more dilute energy.

The solid nature of coal has influenced not only its competitive strength in early years but also its competitive weakness of later years. When coal is mined, it must be broken away from its native confinement. The pieces must be physically loaded and then (although some coal gets burned in the form in which it leaves the mine) moved out of the mine to a cleaning plant, dumped, ground into smaller pieces, separated from the processing water and again picked up and loaded for transporting. It should not be inferred that these are separate steps. They are not; in modern operation the sequence is continuous and automatic, but it does call for equipment, labor, and expense all related to the fact that coal is solid. At the destination, the coal must be unloaded again and then moved through another series of steps, all required because of the solid nature of coal, before it reaches the burning device. When it burns it produces an ash that must be removed. The mechanics of producing, delivering, and using a liquid or gas are much simpler, although, to be sure, the liquid and gaseous fuels go through their own processing steps before they are usable.

The rental or availability of storage space and railroad spurs in cities where real estate values are high may be an appreciable factor in the consumer's decision on what fuel to use.

The softness of bituminous coal causes it to abrade and to form dust. The dust is dirty, and this militates against its use in the space-heating market. This, of course, is not true of anthracite.

Architects and consulting engineers prefer the simpler design and fewer potential difficulties associated with the use of liquid or gaseous fuel. The continuing attempts to liquefy or gasify coal, going back many years, and the present development of the coal pipeline, are attempts to overcome the disadvantage of the solid state.

At the same time, the solid state has an advantage in some uses. Coke not only supplies heat in smelting processes, but physically supports the ore mass.

As to oil, its liquidity has constituted its most distinct advantage. Small compact engines have been built around this trait and are now

thoroughly established as an almost unchanging part of present-day technology. Nearly a fifth of all the energy consumed is used to run motor vehicles, diesel locomotives, and aircraft. If coal can be made effectively "liquid" so that it can be used in turbines, it may recapture part of this market.

Yet, because it is a liquid, oil has a disadvantage with respect to gas. With gas, the user need only turn a valve, whereas to use oil he may have to provide storage space and tanks, and unloading docks or access roads and truck turnaround space. He may have to go to the added effort and expense of installing equipment to control air pollution. Oil, being a liquid, has dissolved in it constituents that sometimes foul equipment and leave a greasy soot that many homeowners dislike.

The heat of gas—and of electricity—can be distributed evenly more readily than can the heat of coal or oil, and the heat level can be maintained indefinitely. Gas flame can be pinpointed in a way that no other fuel permits. Still, the physical nature of gas is not all advantage. Explosions do occur, as indeed they do with oil. Because gas *is* a gas, it must be transported by pipeline, and it cannot go to market unless a pipeline will take it there, not only physically but economically. Oil, on the contrary, can choose a pipeline, barge, tank car, or truck as fits a specific competitive situation. It is this transportation feature regarding gas that has engendered the effort to liquefy it.

SUPPLY

The cost of energy starts with the cost of the primary material. To now, there has been no lack of coal, oil, and gas in the ground that would exert an upward pressure on price. As implied in the chapter on the comparison between requirements and supply, this promises to continue to be true. In terms of dollars having a constant value, the cost of finding, developing, and producing oil and gas jointly appears to some observers to have been fairly constant and on average could well remain so for some time; the great coal resources of the country make this even more probable for coal.

Another element of supply as it affects competition is assurance of delivery. International crises have sometimes caused oil shortages in particular markets, and this is sure to happen again some time or other. Work stoppages in the bituminous coal industry have caused disruption in delivery, but there has not been an industrywide strike in the coal industry in over 12 years, and railroad strikes also are much less a matter of concern than formerly.

PRICE

A distinction must be made between the delivered price of a fuel and the price at the pithead or wellhead. Both are quoted in economic discussions of fuel competition. It is not always easy to remember that a fluctuating transportation cost must be added to the field price and that sometimes this is greater than the cost of the fuel itself.

Delivered price is normally both an ambiguous figure and an incomplete one. It is ambiguous because it is quoted in terms of the natural unit—ton, gallon, or cubic feet—whereas it is not the natural product burned that is significant but the energy the product provides. It takes 4⅛ barrels of heavy oil or about 25 M c.f. of gas to provide the same amount of energy as a ton of coal.

The delivered price of a fuel is an incomplete figure because to it must be added the cost of equipment and labor needed to use it. Whereas to use gas one need only install an appropriate burner and turn a valve, to burn oil or coal he must provide a variety of other equipment and services. Both delivered price and utilization cost are taken into account when a consumer makes his choice of fuel. In some cases, the differences between the fuel cost and the "cost as consumed" may be quite large. For example, the estimated cost of a 10,000-pounds-per-hour boiler unit, installed, is about $16,000 for gas and $35,000 for coal. The coal unit costs the more because it requires equipment—such as a stoker, storage bins, and ash-removal facilities—that the gas unit does not and because of higher installation costs. As a result, gas can be dearer than coal in terms of delivered B.t.u.'s, yet the lower capital charges can make gas the more economic overall. On the other hand, the aggregate saving in the cost of coal at the plant gate over a period of years may more than offset the higher capital costs. In larger boiler units, in those areas of the country where coal is economic, this is usually the case.

TRANSPORTATION

Geography initially establishes the general patterns of fuel consumption and is responsible for the location of many fuel-consuming industries. The reason is the absence of a transportation cost. The coke-oriented steel industry, for example, had its origin near the coalfields of the Appalachians; few, if any, significant carbon black plants operate outside of the oil and gas fields of the Southwest. Generally every fuel is cheaper at its point of production—at the wellhead or mine mouth—than is another fuel that must be transported to that same location. Gas originating in the Southwest is transported through pipelines that traverse near the coalfields, yet in West Virginia, Ohio, and other eastern coal States virtually all the electric utilities use coal. Then, as these fuels move toward more distant markets, the relatively higher unit transportation costs for coal dispel some of this locational advantage.

This element, transportation, is what makes interfuel competition so severe in those areas having little or no native energy resources, such as along the Atlantic seaboard, particularly in New England. In order to compete, the several fuels must be priced approximately the same on a B.t.u. basis as delivered, particularly in industrial markets. Even for space heating, the preference premium paid for gas cannot get too high.

Transporting coal always comes high, constituting on average throughout the United States more than four-tenths of the delivered price of bituminous. From a given region of production, the delivered price of coal is directly related to the distance traveled.

The cost of moving oil is low or high depending on how the movement is made. Heavy fuel oil or crude oil can be shipped from the gulf coast or from the Caribbean to the east coast cheaply, but from there it moves by rail, barge, or truck at costs that are roughly comparable to the cost of moving coal. The low cost of marine transportation is one of oil's major competitive strengths, especially in those locations that can be supplied directly from the tanker. The pipeline transportation of gas is substantially less than the cost of moving

coal or oil by rail, but higher than the cost of moving oil (or coal) by ocean transport.

TABLE 40.—*Prices at point of production*

	Oil—Bunker C—Posted prices [1]				Natural gas [2]		Bituminous coal, dollars per ton [3]

[1] Platt's Oil Price Handbook.
[2] Bureau of Mines.
[3] Dec. 31, 1959.

Table 40 shows the postwar pattern of prices, at points of production, upon which U.S. transportation charges are mounted. The prices shown for heavy fuel oil are posted prices, but for the gulf coast these are representative of actual sales price. (Posted prices for gulf coast bunker C oil are not usually subject to discount.) Caribbean fuel oil is subject to discount, however, by unknown amounts, so that sales price is cheaper than posted price. According to the table, the price of heavy fuel oil at the point of production, and as measured by its heat content, has been nearly twice the price of coal at the mine since about 1956, while the price of gas has been substantially less than the price of coal. (New contract prices for gas sold to pipelines have been going up, and the contract prices now being negotiated make the price of gas equivalent to that of coal at $4.37 a ton, or substantially the same for the two.) The fact that coal has difficulty competing with oil in markets near the ports of entry is a measure of the high transportation cost that coal bears.

With its relatively high cost in eastern harbors and high overland transportation charges, the market for heavy fuel oil is confined to a strip bordering the waterways, about 125 miles inland from the coast and 20 miles each side of the major riverways. Each mile overland adds more to its delivered price while reducing the delivered price for coal at the same location. The point is soon reached where it is uneconomic to move residual oil farther inland, and coal and gas then compete for the market under similar considerations.

Gas has much farther to go, generally, than coal, and its initial large price advantage over oil and lesser advantage over coal are ultimately overcome, despite its low transportation cost. The States of Vermont and Maine use no natural gas for this reason.

In concept, there is a degree of similarity in the pricing of transportation services for all three fuels. The sale of interruptible gas represents an adjustment in transportation charges, and so is analogous, in this sense, to the reductions in rail rates covering the movement of coal to New York Harbor and of residual fuel oil into New Hampshire in order to sustain competition. (See Part VII: Policies, Laws, and Regulations.)

JOINT PRODUCT CONSIDERATIONS

All three of the major fuels are produced or transported as though they were jointly produced or transported with other products. Electricity, too, is sometimes a joint product. This factor has an impact on pricing and competition.

Coal mining yields several products in the form of different sizes, and aside from what is deliberately produced some fine coal is unavoidably produced in coal-cutting operations. Coals of special quality also are produced for specific markets. In some mines the successful extraction of metallurgical coal requires the mining of a certain proportion of steam coal as well, and in many instances availability of metallurgical coal therefore is directly related to the market for steam coal; in other cases the reverse is true. In the opposite direction lack of demand from the steel industry can and does send metallurgical coal into the steam market.

Oil and gas are produced jointly, of course, and both are frequently produced from the same well. The proportions differ. The industry can shift its efforts somewhat between the two, but it can never be sure whether successful exploration will result in oil or gas.

Heavy fuel oil is a byproduct of refining in the United States. As with byproducts generally, the minimum price required in its sale is an amount large enough to balance out-of-pocket transportation and production costs. However, the lower the price, the more the incentive to install equipment to convert it into other and more valuable products. This is happening now, the yield of heavy fuel oil having been declining markedly in the United States for well over a decade. On the other hand, heavy fuel oil of foreign origin is not a byproduct, nor is it priced as one. It is a prime product at all Western Hemisphere refineries outside the United States and Canada and accounts for the bulk of their total output.

The electricity generated at Government-sponsored power facilities is frequently a byproduct. Power from the St. Lawrence Seaway is a byproduct, so to speak, of the principal objective to improve transportation, and in Western States it is a byproduct of an irrigation objective, along with conservation and recreation. This byproduct is marketed in direct competition with the fuels. Similarly, electric generation related to the atomic energy and nuclear power programs also may be called a byproduct.

Transportation, too, has its joint-product aspects. Transportation of coal is a joint service with transportation of other bulk commodities and competes with them with respect to rates and for rolling stock. There is also an analogy in marine transportation, in that tankers that would otherwise be idle are sometimes used in transporting grain. Natural gas pipelines sometimes find that they have idle capacity in

offpeak periods, which idle capacity, in the sense that it is unavoidably created as a result of supplying another market, can be called byproduct; as is normal in byproduct economics, the item is sold if a market exists and if it is economically feasible to do so.

TECHNOLOGY

The effect of the technology of exploration, production, and transportation on competition gets incorporated in the cost and price of the product, which have been discussed above and need no further reference here except to draw attention to the record of the coal industry. Even though wage rates and the cost of materials and mining machinery increased an average of 70 percent during the decade 1950–60, the average price of coal f.o.b. the mine has managed to stay firm as a result of the cost-controlling effect of mechanization.

Of more immediate relevance to competition is the technology of use, which has acted particularly to the detriment of coal. Annual retail deliveries of coal (mainly for space heating) declined by about 55 million tons from 1950 to 1960 with the switch to oil and gas, and railroad use of coal dropped 60 million tons in the same period as the railroads converted from steam to diesel engines. Thus these two factors alone reduced coal consumption by about 115 million tons a year, or nearly 80 percent of the total decline in the nonutility areas of consumption. Conversion of ship use from coal to heavy fuel oil and improvements in iron smelting claimed an additional 25 million tons of annual output.

Another technologic development has been the progressive improvement is what is called heat rate, by which is meant the weight of coal (or B.t.u. content) used in an electric generating plant to produce 1 kilowatt-hour of electricity. This is described in detail in the chapter on the technology of electric generation. As recently as 1950 the heat rate averaged about 1.2 pounds of coal per kilowatt-hour; in 1960 it averaged less than nine-tenths of a pound. This reduction over the past 10 years alone "cost" coal some 60 million tons a year at present rates of electric generation. Generation of electricity from oil and gas has experienced similar but less striking improvements in efficiency.

Another facet of technology and its impact on fuel competition relates to small boilers, those that serve the general industrial market as opposed to the electric utility market. The major change in industrial energy utilization has been the trend toward what are called package boilers, by which is meant boilers assembled at the factory and shipped as one piece, with consequent savings in cost, particularly of installation. The package boiler is much more adaptable to oil or gas firing than to coal firing, and can be designed for much higher capacities per dollar of cost or unit of size.

Still another area of technologic change is now beginning to erode the coal market. Until about 3 years ago the metallurgical fuel market was considered captive to the coal industry. During the past 50 years coke accounted for nearly all the fuel used in blast furnaces, but now oil or gas can be injected with the air blast, reducing the amount of coke needed. Coal technologists are moving to combat this by injecting coal with the airblast.

GOVERNMENT POLICY

Government policy has such pervasive influence that a special part of this report is devoted to it. It relates to competition in many ways: Through its impact on supply, ranging from limitations on production (oil and anthracite) to controls of imports (oil) and control over construction of facilities (gas and electricity); through direct competition between Government and industry in electric power; in its impact on prices and costs, both indirectly through import duties and other taxes and directly through control over sales contracts, utility ratemaking, and cost of transportation; and in control of the end use of the fuels, i.e., "inferior use" of gas (the *Transco* case) and air pollution. (See part VII.)

A point not previously discussed in detail is that different jurisdictions of Government sometimes pull in directions that have opposite effects. Several different agencies regulate, control, or otherwise influence competition among the fuels, and each tends to act independently of the others within its own interpretation of its charter. We have made no attempt to itemize such occurrences, but the following instance has been brought to our attention. While the Department of the Interior maintains quotas against the import of foreign oil in order to help sustain the American industry, the maritime laws of the United States (through the requirement that coastal movement of oil be in relatively high-cost U.S.-flag tankers) operate in the opposite direction by giving foreign oil and oil products a price advantage over domestic fuel.

There are other instances, of course, in which Government policy pulls in only one direction. For example, Government is a large consumer of fuel, and its procurement practices therefore exert important competitive pressures. A specific example in this regard is the Tennessee Valley Authority, the largest single purchaser and consumer of coal in the United States. In 1960 it purchased about 19 million tons of coal (to the exclusion of other fuels), mostly from mines that sell also to public utilities. Of this amount, 1,800,000 tons consisted of spot purchases each under $10,000, at prices generally lower than paid on term contracts and in some instances from the same supplier. Spokesmen for the coal industry say that the result of TVA purchases is a pressure on the producers to charge other utilities the same low price they charge the Tennessee Valley Authority. In making contracts the TVA can take advantage of special rates applicable to transportation of Government property. Another illustration is the setting aside, in Government purchase contracts, of certain portions of Government fuel procurement to be met by small producers.

Two final points may be made:

Hydropower produced by public projects, both Federal and State, is sold to electric utilities sometimes in competition with fossil fuels. A case in point is the operation of the Power Authority of the State of New York, which has arranged to sell much of the electric energy from Niagara Falls and the St. Lawrence project to utilities in the State. Blocs of power have been sold to the Niagara Mohawk Power Co., Rochester Gas & Electric Co., and New York State Electric & Gas Co. These companies operate a number of large coal-burning

generating stations. Through the distribution facilities of these three utilities, the power authority has arranged also to distribute electricity to other companies beyond the State. Between 1958 and 1961 the Niagara Mohawk Co. decreased its coal usage from 3.2 million tons to 2.5 million tons while during the same period increasing its purchases of hydropower in coal equivalent to 3.3 million tons.

Much public regulation initially had no intention of influencing competition among fuels. The legislation was for the purpose of protecting the American consumer in his direct relation with a particular producer or was related to some other aspect of national interest. Some Government actions thus now find themselves in an environment for which they were not designed and on which they therefore have an influence not foreseen. For example, the commodity clause of the Interstate Commerce Act (1906) prohibits railroads from owning properties that produce the freight the railroads haul. A second clause exempts bulk transportation by water carriers from regulation. At that time coal was the principal fuel, and the railroads the principal carriers, and their competitive position was not affected. Now there are three basic fuels and additional methods of transportation, and the competition is keen.

REGIONAL FACTORS

Aside from the circumstance that fuels are most widely consumed near their points of production, fuel consumption reflects also regional shifts in industrial concentration. The migration of the New England textile industry to the South, for example, added to one region's fuel consumption while subtracting from another's. When such shifts occur between one native energy region and another, one fuel may be substituted for another. There is no information, however, on how much this amounts to except in an illustrative way here and there. According to the latest Census of Manufacturers, iron foundries in the coal-consuming regions of New York, New Jersey, Pennsylvania, Ohio, Illinois, and Michigan reported less activity for 1958 than for 1954, while foundries in the gas-using areas of California and Texas reported a substantial increase in activity.

An example of the regional factor is in the development of nuclear energy. By some happenstance, the first two commercial reactors—Shippingsport, Pa., and Dresden, Ill.—are in coal regions.

CONSUMER PREFERENCE

Consumer preference for a particular fuel is such a common phenomenon that little need be said about it here.

Despite the fact that natural gas and heating oil are more expensive than coal in some areas, they are preferred by householders to such an extent that they have taken over a large segment of the space-heating market. Gas is taking away markets from oil for the same reason—simple preference.

In the industrial market it is technically possible to conduct numerous operations with any fuel, but often the user prefers one over the other because it makes his task easier, although, to be sure, the choice is influenced also by technical considerations. As already indicated, the heat of gas and electricity can be distributed more readily than the heat of coal or oil, and the heat level can be maintained indefinitely.

Individual Markets

RESIDENTIAL AND COMMERCIAL

In the postwar period the use of electricity in the residential market has grown at an average compound rate of 11 percent a year, gas at 10 percent, and petroleum at 7 percent, although the rates of growth have been much lower in the past 5 years. The use of coal has declined at a rate of 10 percent a year. In 1960 oil and gas each held about 40 percent of the market, and coal and electricity each about 10 percent.

The commercial market is primarily for heat and power—in hospitals, apartment houses, schools, and office buildings—and resembles the residential market. It is fairly small. In 1960 the market shares were gas 50 percent, oil 17 percent, coal 10 percent, and electricity 23 percent.

The top space in figure 91 shows the postwar changes in the deterioration of the retail coal market; retail deliveries (i.e., the residential, commercial, and some "offtrack" industrial markets) in 1960 totaled only 30 million tons or 67 million tons less than in 1947. Most of this decline was due to the switch to oil and gas for heating. The use of electricity for residential heating may enable coal to recapture some of this market.

Of the retail market remaining for bituminous coal about 60 percent is in the Midwest, primarily in Ohio, Indiana, Illinois, Michigan, and Minnesota. Most retail coal has been mined in the southern Appalachian area in the States of Virginia, West Virginia, and Kentucky. Even though the retail market declined nearly 20 percent between 1957 and 1960, these three States still supply about half of the retail market and any further loss would be taken mainly by them. The primary market for anthracite is Pennsylvania and in New England and adjacent States.

The price relations involved in the residential market are shown in figure 92, which shows indexes back to 1935 for added perspective. During this 25 years the average retail (delivered) prices of coal and oil have been consonant, indeed almost identical. The rapid rise in the price of each right after World War II was the result of the removal of price controls, and the rise ended as soon as they reached the competitive ceiling imposed by gas. Since that time the prices of the three have reflected their competitive interdependence. In 1948 and again in 1957 oil appears to have tried to push ahead, but each time was pulled back by the competition of the other two. As noted, the series shown for gas is for space heating only and does not reflect the average price paid by residential user for all gas. For example, from 1950 to 1960 the space-heating index rose by 44 percent. During that same period the average price for all residential gas as reported by the American Gas Association rose by 17 percent.

But these are national averages, whereas competition is more of a local problem. Figure 93 shows price relationships in Boston, a city for which there are data and that is in a hotly competitve area. Until 1953 the gas used in Boston was manufactured gas, made locally from coal and oil, and its price necessarily reflected the competitive

prices of these fuels. As the price of manufactured gas rose, it provided an invitation for natural gas to come in. Once there in abundance, natural gas had to be competitive, and the price sought out a level that made it so.

INDUSTRIAL

There are two parts to the industrial market: electric power generation (mainly public utility) and general industrial use.

Power generation

The power-generation market is probably the best mirror of what happens in interfuel competition. Minor differences in delivered price, multiplied by very large quantities, can amount to large sums of money to the user. Costs associated with utilizing fuels—handling, storage, and entry facilities—also are large. The electric utilities are among the most well-informed buyers of energy and the quickest to take advantage of price differentials and changes in technology of utilization. Since electricity can be generated equally well by gas, oil, or coal, no single fuel has an impregnable position in this market.

TABLE 41.—*Cost of fuels at steam electric powerplants, 1952–60*

(Cents per million B.t.u.)

	Coal	Oil	Gas		Coal	Oil	Gas
1952	27.2	22.1	14.5	1957	27.3	24.4	19.5
1953	27.3	22.3	16.7	1958	27.4	25.6	20.7
1954	26.1	22.6	17.3	1959	26.5	25.2	21.2

Figure 94 shows fuels utilization by areas for thermal electric utilities in 1952, 1957, and 1960, which bracket the years for which good data are available. Different fuels predominate in different regions. The coal share declined nationally very slightly between 1952 to 1960, and somewhat more from 1957 to 1960. By regions, the pattern has been diverse. To illustrate: In region II–A, coal's share declined while the shares of oil and gas rose; in region II–B coal rose while oil and gas declined. These relationships refer only to the steam electric market and may differ substantially from those calculated for total electricity generated. In region IX, for example, the 88 percent shown for gas is equivalent to less than 1 percent of all electricity generated in that area, which is served primarily by hydropower.

The National Coal Association has tabulated electric utility consumption of coal in what it calls the "coal-competitive area," the area cross-hatched in figure 94. The market share of each fuel in this area is shown in figure 95. It appears that no single fuel has been able consistently to undersell the others. In recent years, most of the new electric generating facilities constructed east of the Mississippi River have been designed to use coal as the primary fuel, although there are major exceptions. In electric powerplants placed in service between 1955 and 1960 in this region, coal constituted 94 percent of all fuel used in 1960; oil 2 percent, and gas 4 percent. The

FIGURE 24.—Percentage of the steam electric generation market held by coal, oil, and gas, by regions.

SOURCE: National Coal Association, "Steam Electric Plant Factors."

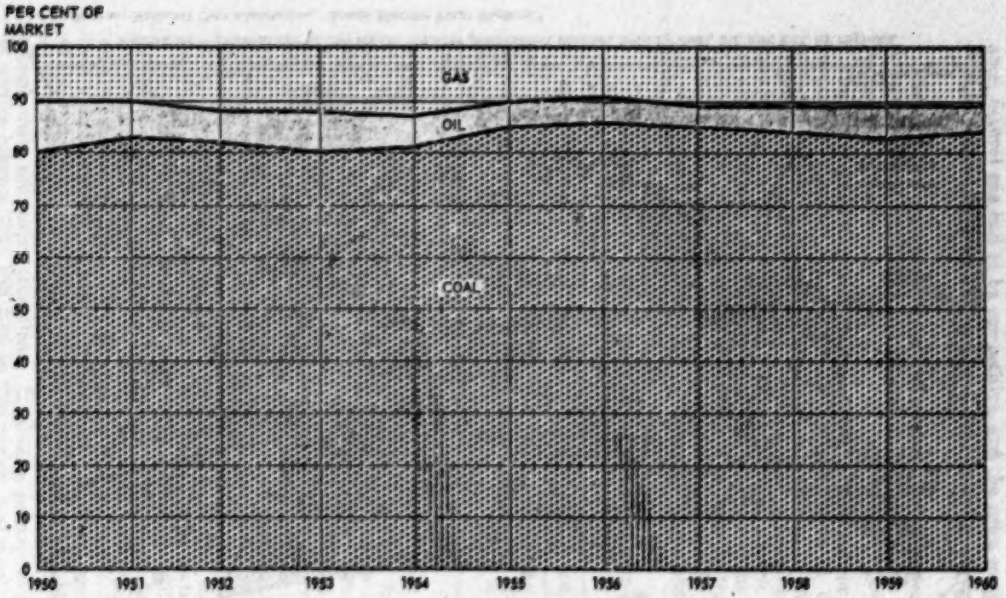

FIGURE 95.—Proportions of coal, oil, and gas used for electric power generation in the "coal-competitive area," defined by the National Coal Association. See figure 93.

combined market share of oil and gas in the coal competitive area in 1960 was equivalent to 33 million tons of coal out of a total market equivalent to 207 million tons. Since 1952 oil and gas have increased their joint participation in this market by the equivalent of 8 million tons of coal, coal itself by 70 million tons.

Most discussions about interfuel competition relate to the eastern seaboard, with special emphasis on New England. In New England, gas pipelines reach no farther than southern New Hampshire; Maine and Vermont have no natural-gas supply at all. Oil is the dominant fuel in Maine, New Hampshire, and Massachusetts (to where coal haulage is longest); coal is dominant in Vermont, Connecticut, and Rhode Island. With so little gas entering, the competition in this area is mainly between coal and residual fuel oil.

A relatively small amount of gas is used for power generation in the Ohio-Indiana-Illinois region as a result of the prime considerations of price and availability of underground storage. In the Southwest, on the other hand, almost all steam-generated electric power has been from gas, but here and there this is changing. The new Cholla plant of the Arizona Public Service Co. is designed for pulverized coal alone, and its Four Corners plant, being built, is a mine-mouth plant also designed for pulverized coal only. The Public Service Co. of New Mexico too is planning a mine-mouth plant.

The operations of the Consolidated Edison Co. of New York present a typical case history. This company is the largest utility company in the Metropolitan New York area. Its present steam-generating capacity is equivalent to 10.6 million tons a year. The company estimates that its fuel requirement in 1962 will be supplied 51 percent by coal, 25 percent by oil, and 24 percent by gas. In addition, the equivalent of 1 million tons of coal will be provided by the company's nuclear facilities and by hydropower from the Niagara Mohawk System. Also Consolidated Edison is constructing a new station at Ravenswood, Long Island, which will be equipped to burn only gas and oil. The company [1] reports that it expects to save $30 million in coal-burning equipment, cinder-catchers, coal and ash-handling equipment, water-frontage improvements, and other items realted to the use of coal. The planned energy consumption is the equivalent of about 1,500,000 tons of coal a year. On April 1, 1962, Consolidated Edison began to switch its East River plant from coal to residual oil in order to control air pollution, having been restricted in the use of gas (the *Transco* case). In early 1963, when the conversion is complete, 40 percent of boiler capacity will be oil fired. The converted boilers burned 450,000 tons of coal annually.

Figure 96 shows the prices (in cents per million B.t.u.) of coal, oil, and gas as reported by Consolidated Edison from 1950 to 1961.

An argument advanced by the coal industry regarding competition between residual oil and coal is that the effect upon the price of coal ripples out through the entire U.S. coal market. The producers in the northern Appalachian region who sell to east coast consumers sell also to consumers in other directions. These other customers will not pay more f.o.b. the mine than anyone else. Producers in other regions then tend to adjust their prices in order to hold their markets against the competition of the Appalachian producers, and so on market area by market area. For example, whenever a producer in Pennsylvania is

[1] Letters dated May 21 and June 26, 1963.

forced to cut his price on coal sold to customers in New York and Philadelphia, the same price concessions are demanded by customers in western New York, Ohio, Michigan, or Minnesota, and the concessions are quickly echoed in the coalfields of Ohio, Indiana, and Illinois.

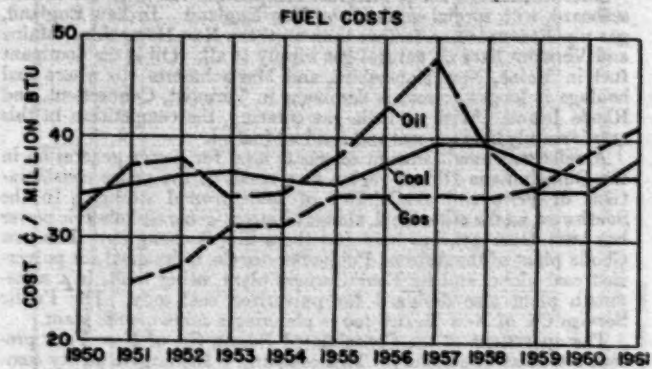

FIGURE 90.—Fuel prices paid by Consolidated Edison Co., 1950–60.

General industrial

General industrial fuels are used for process heat, boiler heat, or as raw materials.

The general industrial market has many of the aspects of power generation, with the major difference that the average industrial customer uses less fuel than the average powerplant, and that the capital charges are probably more prominent in relation to fuel costs. Also, these general industrial consumers are usually less able to achieve the efficiencies that power companies obtain with their larger boilers. For these reasons the general industrial market is probably not quite as sensitive to what it pays for fuel. Nevertheless, fuel costs together with consumer preference and technology have resulted in a significant decline in coal sales in the general industrial market in the postwar period, though not much of a decline has occurred since the mid-1950's. (See fig. 90.)

Because the data are so sketchy, it is not always possible to assign to competition a loss that one fuel may sustain at a given time, or that another may gain. One factor is the tendency in the industry toward purchasing power from electric utilities rather than generating one's own. In 1947, for example, industry generated about 30 percent of its electric power requirements, but less than 20 percent in 1960. There thus occurred a transfer of fuels from the industrial sector to the utility sector. This trend would be expected to be pronounced in the areas most heavily industrialized.

From 1954 to 1958—the latest 2 census years—coal's share of manufacturers' heat and power market (which excludes metallurgical coal and all raw material uses of the fuels) rose from 34 percent to 36 percent, oil's share rose from 11 percent to 16 percent, and that of gas declined from 56 to 48 percent. In the area east of the Mississippi

coal's share rose from 41 to 51 percent. In region IV oil's share rose from 10 to 15 percent, while in region IX it fell from 55 to 30 percent. Gas' share declined substantially in region II, but increased in region III. A different time span might show different relationships; both 1954 and 1955 were recession years, but no more satisfactory data are available.

With respect to the competitive prices involved, there is very little information. Data from the 1958 Census of Manufacturers show that in the manufacturers' heat and power market the delivered price of coal averaged 37 cents per million B.t.u. and that gas averaged 28 cents. East of the Mississippi both prices averaged about 37 cents. Available figures for oil apply to too great a variety of products to yield anything meaningful.

According to the American Gas Association, the average price of gas sold to industrial users rose by almost 60 percent from 1950 to 1960. With respect to interruptible sales alone, which is a point of common discussion, data for comparison are not available on prices of coal and oil that compete with this type of sale (about two-thirds of which is for boiler fuel, and one-third for process heat). However, in those regions where coal is a significant factor the average cost of coal to electric powerplants is below the equivalent average cost of interruptible gas.

Since 1949, residual fuel oil imported into the east coast has ranged between 17 million and 49 million tons of coal equivalent a year. This enters into both the general industrial and utility markets. Under the 1969 quota it was entering at an annual rate of 49 million tons of coal equivalent, of which 10 million tons was used in ships' bunkers in foreign trade and would not be supplied by domestic oil. If the importation were stopped, coal, natural gas, and domestic petroleum products would supply roughly an equivalent amount, in unknown proportions. Any additional coal produced would come largely from Pennsylvania, West Virginia, or Virginia, but its entry would be slow because many installations are equipped to burn only one fuel; the loss would be borne by the Netherlands West Indies and Venezuela. Any additional gas would probably come from Louisiana and Texas.

TRANSPORTATION

The table below gives the latest reliable data on the use of fuel in transportation. According to it, oil accounts for over 90 percent of the total. Figure 90 shows the rate at which coal has dropped out of this market, from 110 million tons in 1947 to 2 million in 1960.

Oil may not necessarily maintain its preeminent position in this market. The electrification of railroads and liquification of coal both provide potential threats.

TABLE 42.—*Fuels used in the transportation industry, 1955*

[Trillion B.t.u.]

	Direct	Via electricity	Total	Percent
Coal	333	24	357	4.8
Oil and NGL	7,430	5	7,435	91.9
Gas	234	12	246	3.3
Total	8,017	71	8,088	100.0

PART V. UNCONVENTIONAL SOURCES OF ENERGY

Unconventional sources of energy are sources other than coal, oil, gas, wood, falling water, and now atomic energy. They include the sun's heat and light (solar energy), the wind (windpower), the tides (tidalpower), the heat within the earth, the thermal energy of the sea, bacterial life processes, and new exotic forms of generating electricity. The subject is included here for the sake of completeness, and the treatment is brief.

SOLAR ENERGY

The traditional commercial uses of solar energy are in the evaporation of brine in open pans for recovery of the salt, in the drying of fruit, and to hasten plant growth in greenhouses. The attention to unconventional uses is with the intent of trying to capture and apply the heat to various other ends, depending on temperature desired, and for direct conversion into electricity. Low-temperature uses are many, including the heating of water (which then may be used for home heating, for example) and in the conversion of saline to fresh water. Solar conversion of saline water is one of the techniques being investigated by the Office of Saline Water of the Department of Interior. At higher temperatures the heat may be applied to furnaces or to run engines of various types—steam engines, for example—either for direct transmission of power or for generation of electricity.

The heat of the sun is caught by a reflector and focused where wanted. The focused beam can achieve temperatures of thousands of degrees, high enough to melt metals, and solar heat already has been used in experimental metallurgy.

Focused sunlight can be used in thermoelectric devices (creating an electric current by heating the junction of two dissimilar conductors). (See below.) A number of satellites are powered by photovoltaic cells (the kind used in photographic exposure meters), which are solid-state electronic devices that convert light into electricity. Other specialty uses are possible.

WINDPOWER

Windmills for pumping water are well-known devices, and the reference to windpower as an unconventional source of energy is to its widespread use, and mainly to produce electricity. Electric generators run by windmills are in commercial production or operation in Denmark, Canada, France, Germany, South Africa, the Soviet Union, the United States, the United Kingdom, and elsewhere. Interest is expanding.

Thousands of generators of capacity of 3 to 4 kilowatts are in use in different parts of the world. A 100-kilowatt wind-driven generator has been operating successfully in Denmark for several years, and a 100-kilowatt generator has been installed also in the Isle of Man.

A 640-kilowatt generator has been tested in France. All these larger units are designed to feed energy into existing alternating-current networks.

TIDAL ENERGY

Tidal energy is contemplated as a source of hydroelectric power wherever tides are abnormally high. The tides in the Passamaquoddy area of the Bay of Fundy have been viewed in that light for some time. A 235,000-kilowatt plant was proposed in 1924, and $7 million were spent on the project by the United States in 1935–36. The latest interest is expressed in a report of the International Joint Commission dated April 1961. A tide-driven prototype plant generating 9,000 kilowatts was inaugurated successfully in France (at Saint-Malo, Brittany) on November 4, 1959; interest is alive in a project on the La-Rance River nearby that will have a capacity of 240,000 kilowatts, planned to deliver 97,000 kilowatts of winter power and 195,000 kilowatts of peak power. The U.S.S.R. is said to be interested in several projects, including one at Mezen on the White Sea.

THERMAL ENERGY OF THE SEA

Proposals have been advanced to make use of the difference in temperature between the surface water of the sea, heated by the sun, and the colder water below. Again, French engineers have been the leaders. The interest is based on the thermodynamic principle that heat can be converted to mechanical energy when there exists a difference in temperature between two heat sources. The temperature differential is analogous to head in a waterfall. The power that may be produced is proportional to the square of the difference, so that even small differences—if they are not too small—can be utilized. In certain ocean expanses, the temperature difference is consistently great enough, about 20°C., for this purpose.

GEOTHERMAL HEAT

Reservoirs of underground heat underlie the volcanic regions of the world. They are commonly identified by the presence of hot springs and fumaroles, and the heat can be withdrawn and used either in the form of hot water or steam under pressure. If the natural steam has sufficient volume, temperature, and pressure, it can be directed through a turbine to drive an electric generator, or the heat can be used to generate steam. Geothermal plants in Italy had a capacity of 274,000 kilowatts in 1954 and operated 300 days a year to provide 2 billion kilowatt-hours annually. A 275-kilowatt plant is in operation in the Katanga mining region. In Japan, New Zealand, Mexico, and Chile either plans have been made, designs drawn, or construction is in progress. The Pacific Gas & Electric Co. in 1959 placed a 12,500-kilowatt plant in operation at Sonoma, Calif., north of San Francisco, and has since expanded the capacity.

The steam fields of Iceland have long been used for heating purposes.

THE BACTERIAL FUEL CELL

The fuel cell, discussed more fully below, is included here as an unconventional source of energy because of the demonstration within

the past 2 years of a bizarre cell fueled with a common and harmless species of bacteria. The bacteria occur in and feed on almost any kind of organic matter and generate electricity in doing so: corncobs, peanut shells, the waste in polluted rivers. They occur everywhere, including abundantly in the sea. Cells generating 2 volts have been built, and model devices have been operated. An intriguing aspect is that the bacteria clean up organic waste matter in the process of converting it into electricity; a papermill, for example, might get its energy from its waste products and at the same time avoid polluting the river running by its door.

The bacteria fuel cell was discovered by a scientist of the Geological Survey—i.e., it is the result of Government research.

EXOTIC WAYS OF GENERATING ELECTRICITY

Five unconventional conversion methods are attracting considerable attention in scientific laboratories:

Thermionic converters, in which electrons "boiled out" of a hot metal surface are used to generate electricity. The device may appear soon in solar-power generators in satellites. One of the most hopeful applications, though at least a decade away, is in atomic powerplants, where the thermionic devices would use heat that is otherwise wasted in the steam-cycle. Such units would give added efficiency to power stations, augmenting the steam-turbine generator.

Thermoelectric generators, defined above. There is considerable talk about specialty applications but not much optimism about the generation of large amounts of economic power. Known materials do not offer any hope of efficiency above 10 percent, but the operation is simple and the materials would last indefinitely. Converse to the generation of electricity by heat, the passage of an electric current heats the conductor and, oddly enough, passage of the current in the opposite direction cools it. Thermoelectric cooling devices are already appearing commercially.

Magnetohydrodynamic generators (MHD), which use a hot steam of plasma (ionized gas) instead of a copper wire as the conductor. Few ideas of modern times have posed tougher materials problems. Some observers feel that there is little if any hope of finding an electrode material that can withstand the required temperatures for anything like the period of time that would make such devices economic for large powerplants, which is the field in which the application is usually talked about. Few specialty applications have been suggested. The idea is to combine MHD with conventional systems, to achieve higher efficiencies. Most observers judge that MHD is the least promising of the schemes discussed here.

Fuel cells, batterylike devices in which a chemical substance reacts to produce electricity without flame, smoke, or noise. In the fuel cell one of the chemicals is oxygen (pure or in the form of air), the other is hydrogen or an organic material. The chemicals are fed continuously into the cell, which is able therefore to generate electricity continuously and indefinitely.

The fuel cell is still an experimental idea, although close to some special commercial applications. Experimental fuel-cell tractors and forklift trucks have been tested. A small number of fuel cells are

being delivered to the Armed Forces; the first application might be for a backpack generator that can operate frontline electronic gear. Such specialty applications, where convenience is more important than cost, could become important soon. Bulk power generation (central station plants) would require a cell that operates on cheap hydrocarbon fuels (coal, oil, natural gas). Some experts believe such cells may be developed within a decade; others believe this is far too optimistic. The fuel cell for the home or for automotive use seems a long way off. In general there is more optimism about the fuel cell than about any of the other new energy conversion schemes.

Comparison of Coal-Fired and Nuclear Power Plants For the TVA System

• • •

Conclusions

It is evident from the results of the evaluation that the nuclear alternatives have a decided advantage over the coal-fired plant and that either a BWR or a PWR nuclear plant at Browns Ferry would be a decided economic choice over a coal-fired plant at Cumberland City. Comparing the present values of the investment cost plus the total production costs for the first 12 years of plant operation of each of the alternatives indicates the amount of this saving is $21.9/kw for a PWR plant and $35.6/kw for a BWR over the coal-fired plant. Although the capacities of these plants are not identical, an indication of the magnitude of this saving in total dollars is helpful in appraising the alternatives. The dollars per kw saving above amounts to about $43 million if a PWR is installed instead of a coal-fired plant, and $76 million, if a BWR is installed. These represent annual savings of about $8 million for the BWR and $5 million for the PWR. In addition, the nuclear plants have firm prices covering all the equipment (for 1970 and 1971 operation), and firm prices for a longer period on the fuel supply.

There are no technical or other reasons to believe that either a fully operable plant of the BWR or PWR type cannot be successfully licensed and built. The choice then lies between the BWR and PWR. The BWR plant has a $13.7/kw economic advantage over the PWR; based on the capacity of the BWR plant the saving over the PWR has a present value for the first 12 years of about $29 million, or about $3 million annually, for the two-unit plant. In addition to this evaluated advantage over the PWR are GE's offers of a capacity guarantee, an operating assurance, better fuel cancellation terms, and a longer firm fuel supply.

Contract 41-T3 10-17-62 DX 104

Bart,

Enclosed is a draft of a letter which incorporates the basic information that I would like to have in your request for adding the Fidelity Mine as a source under this contract.

We will need the original and one copy of an executed Producer's Statement on the Fidelity Mine. The information that I have filled in on the form enclosed came from the statements that are on file for this source under Contract 38-T12.

You can probably improve on the language that I have suggested for the letter, but the idea is the thing I wanted to be sure was incorporated.

I certainly appreciate your cooperation in working with me to bring this matter to its proper conclusion. I feel that the contract is good for both of us and that we will certainly reap mutual benefits from it.

Tilman.

DEFENDANT'S EXHIBIT 105

October 18, 1962

Mr. E. C. Hill, Chief
Coal Procurement Branch
TENNESSEE VALLEY AUTHORITY
1010 Georgia Avenue
Chattanooga, Tennessee

Subject: CONTRACT 63P-41-T3—Coal for Shawnee Steam Plant

Dear Mr. Hill:

Confirming our telephone conversation on October 17, 1962, we would appreciate being authorized to begin deliveries on the above contract effective October 22, 1962, rather than on the November 1, 1962, date which was established as the initial date when this contract award was made last week. Deliveries during October will be at the rate of 9,000 tons per week and increase to 13,000 tons per week effective November 1, as now provided under the agreement.

We also request that beginning with initial deliveries and continuing until further notice, we be permitted to deliver 50 per cent of the contract weekly schedule requirements from the Fidelity Mine of our affiliated company, The United Electric Coal Companies. The size and quality of coal to be furnished from this source and other data pertinent to this operation are set out on the enclosed Producer's Statement which is provided in duplicate. It would be agreeable with us if you prefer to provide for a separate guaranteed analysis and billing price

per ton on this Fidelity coal so as to minimize quarterly adjustments for quality.

We will deeply appreciate your cooperation in the arrangement of these matters.

Sincerely yours,

FREEMAN COAL MINING CORPORATION

BARTON R. GEBHART
Vice President

BRG:AJ

TENNESSEE VALLEY AUTHORITY
Division of Materials
Coal Procurement Branch
Chattanooga, Tennessee

COAL CONTRACT SUPPLEMENT

To Freeman Coal Mining Corporation
300 West Washington Street
Chicago 6, Illinois

Supplement No. 1
Date October 25, 1962
Contract No. 63P-41-TJ
Plant Shawnee
Name of Mine Various

Attention: Mr. Barton R. Gebhart

This confirms agreement reached between you and J. C. Hill by telephone on October 17, 1962, regarding the initial date of contract shipments and authorization of a supplemental mine source under above contract. This also acknowledges receipt of your letter dated October 18, 1962.

Initial deliveries shall begin under this contract on October 22, 1962, and continue for a period of 120 months thereafter. The Fidelity Mine is authorized as a supplemental source for up to 50 percent of weekly schedule requirements.

Information pertinent to the supplemental source in accordance with the Producer's Statement furnished is as follows:

Producer	United Electric Coal Companies
Mine	Fidelity
Seam	No. 6 (Illinois)
Type of mine	Strip
Size & preparation	*
Shipping point	Du Quoin, Illinois
Via	IC Railroad
Consigned to	Shawnee Steam Plant

(a) *1-1/4" x 0 Scgs. (moisture allowance 3%)
(b) 6" x 0 Cr. to 1-1/4" x 0 - mixed with 1-1/4" x 0 Scgs. (moisture allowance 1%)
(c) 6" x 1-1/4" or int. sizes Cr. to 1-1/4" x 0 (moisture allowance none). All crushing after washing.

The guaranteed analysis for deliveries from the Fidelity Mine shall be as follows:

Total moisture	11.0%
Ash (dry basis)	11.1%
Sulphur (dry basis)	3.4%
Btu/lb. (dry basis)	12,653
Delivered heat content Btu/lb. (as received)	11,261
Btu/lb. (MAM free)	14,233

Effective October 22, 1962, the billing price TVA will pay for deliveries from the Fidelity Mine shall be $2.85 a ton f.o.b. rail cars, Du Quoin, Illinois. This change in price (to the nearest cent a ton) is correlative to the above change in the guaranteed analysis and the contract evaluated delivered cost of 16.00 cents a million

COAL CONTRACT SUPPLEMENT

-3-

To Freeman Coal Mining Corporation

Supplement No. 1
Date October 25, 1962
Contract No. 632-41-73
Plant Shawnee
Name of Mine Various

Btu to the Shawnee Steam Plant (using a freight rate of $0.99 a ton). Your invoices should reflect the new billing price on shipments from the Fidelity Mine.

Separate samples shall be taken and separate Coal Quality Adjustment Reports will be issued each calendar quarter on receipts from the Fidelity Mine. The quarterly quality adjustment shall be applied to the billing price of the Fidelity Mine coal in the amount (calculated to the nearest cent a ton) necessary to preserve the delivered cost of 18.00 cents a million Btu at the Shawnee Steam Plant. The adjustment shall in no way be affected by subsequent changes in steam plant destination of the coal or in freight rates. (See contract Exhibit II for samples of calculations).

All other provisions of the contract remain unchanged.

Please complete the acceptance below and return the copy of this contract supplement to this office. You should retain the original for your file.

Accepted FREEMAN COAL MINING CORP.

FOR IMMEDIATE RELEASE
(Tuesday, January 13, 1970)

JAN 14 1970

NOTE TO EDITORS AND CORRESPONDENTS:

Following is a brief status report on U. S. civilian nuclear power plants for the year 1969:

During the year, electric utilities made known plans for six nuclear power plants. In this period, the utilities ordered seven reactors (five for plants announced during the year and two for plants previously announced) with a total capacity of about 7,169,000 kilowatts.

In 1968, utilities made known plans for 17 nuclear power plants. They also ordered 17 reactors with a total capacity of about 15,630,000 kilowatts.

Status of all nuclear power plants, as of December 31, 1969

	kilowatts
16 operable	4,271,700
48 being built	38,455,200
34 planned (reactors ordered)	30,883,000
8 planned (reactors not ordered)	7,645,000
Total	81,254,900

Attached for your information is a map of the United States showing the location of all present and proposed civilian nuclear power plants for which reactor suppliers have been selected.

Re: United States v. General Dynamics Corporation et al., Civil Action No. 67 C 1632 (N.D. Ill.)
Your file: 60-0-37-920

Dear Sir:

Your letter of February 2, 1968, addressed to Standard Oil Company (N.J.) has been forwarded to me for reply.

I have discussed your inquiry with our operating people and reply to your numbered questions as follows:

1. Humble Oil & Refining Company or an affiliate has acquired, directly or through a trustee, coal rights in approximately 650,000 acres in Illinois, none of which is suitable for strip mining.

2. The information requested is confidential, competitive data which we do not wish to reveal. From a competitive standpoint, the disclosure of this information would be so injurious to Humble, I deem it advisable to protect it as a business and trade secret.

3. Yes. However, further evaluation will be required on some of the coal rights to determine the extent and quality of coal present.

4. Yes. Further geological testing and study will be necessary before all the properties have been evaluated. The results of these tests are confidential, competitive information which we do not wish to disclose for the reasons mentioned above.

5. We do not have sufficient information to answer this question with respect to all of the rights acquired. However, it appears, based upon present studies, that coal will occur below the surface of some portions of the land and that some of this coal is suitable for underground mining and may be suitable for liquefaction. The commercial feasibility of liquefying the coal has not yet been determined. Information with respect to particular tracts is confidential, competitive data which we do not wish to disclose for the reasons mentioned above.

6. You may contact the undersigned if you wish to discuss these matters further.

We hope this information will be of help to you, although for the reasons stated, we are not in a position to comply fully with your request.

Very truly yours,

Richard P. Ryan

Re: United States v. General Dynamics Corporation et al., Civil Action No. 67 C 1632 (N.D. Ill.)
Your file: 60-0-37-920

Dear Sir:

Following your telephone call Tuesday afternoon I asked our operating people for a statement of our purpose in acquiring coal reserves in Illinois.

I found that they look upon these coal reserves as a long-range source of raw material that may be converted into hydrocarbon products, such as gasoline. We are also considering the possibility of making some sales of coal to utilities tributary to our reserves.

I trust this answers the question you raised in our telephone conversation.

Very truly yours,

Richard P. Ryan

GENERAL DYNAMICS CORPORATION

Excerpt from Minutes of Meeting of Board of Directors

Held on September 30, 1966

7. United Electric Coal Companies - Purchase of Stock

The Chairman referred to the discussions at the last Board meeting regarding the purchase of additional stock of United Electric Coal Companies. He reported that, as authorized by the Board, the Corporation had acquired 48,400 shares of UEC from Material Service Employees Profit Sharing Trust at $50.50 a share, which represented the cost to the Trust of acquiring and carrying the stock.

The Chairman then stated that management had considered further the advisability of acquiring the remaining minority interest in UEC and, for various reasons, had concluded that the Corporation should proceed with a plan of acquisition at this time. He asked Mr. Sargent to present the management's views.

Mr. Sargent reviewed for the Directors the charts containing financial data on UEC which had been presented at the

last Board meeting, and noted the amounts that would be required on various assumptions to acquire the remainder of the UEC stock. He stated that the management still felt that the most direct method of acquiring the balance of the UEC stock was through a combination of a tender offer for an additional 170,000 UEC shares, which would bring the Corporation's holdings to slightly more than 90%, and a "short form" merger, available under Delaware law to a 90% holder, under which any remaining minority would be paid the fair value of their shares. He stated that under the "short form" merger provisions, UEC could be merged directly into the Corporation or into a new Delaware subsidiary to which the Corporation would first transfer its UEC shares, in either case by action of the Board of the parent. He stated that if the tender offer were a success the merger would be effected as promptly as possible and steps would be taken to provide management for UEC and to combine UEC and Freeman marketing and other administrative functions and staffs where efficiencies and cost reductions could be achieved. He stated, however, that in the first instance the UEC coal properties and contracts would be held separately from those of Freeman, most probably in the new Delaware subsidiary.

Mr. Sargent then reviewed the various considerations in support of the management view that the minority interest in UEC should be acquired and that Freeman and UEC should be combined as soon as possible, including a review of UEC's limited coal reserves and the resulting problems UEC had encountered in obtaining and keeping long term contracts, the ability of Freeman to provide a back-up of reserves over the long term and finally

the requirement for a new chief executive officer and other key personnel on which action should be taken promptly. He also reported that the New York Stock Exchange indicated its intention to delist UEC within the next few weeks. He stated that, in general, the combination of the two operations made good business and operating sense and would insure the ability of the enterprise to compete more effectively in its market. He stated further that, under all the circumstances, the Corporation's legal staff was not aware of any legal reason why the Corporation should not proceed with the plan.

The Directors discussed the matter of a tender offer price, in the course of which it was pointed out that it is normal in tenders of this kind to offer a premium over market of between 15% and 20%. Mr. Sargent then reviewed the market action of UEC stock over the last few months in which he noted that in July, when the possibility of a tender offer was first discussed, UEC was selling at 39-1/2, and that on August 3, the day before the meeting of the Board at which the tender offer was to be considered, the price of UEC had risen to 49. He stated that subsequent to the August meeting the price of the stock dropped sharply. The current market is about 42. Mr. Sargent then stated that, in his opinion, the Corporation should not, under present conditions, pay more than $50 a share on the tender offer, which provided a sufficient premium over the market. The consensus of the Directors was that $50 a share would be a proper offering price at this time.

Mr. Sargent answered questions by various Directors about the Corporation's cash position, the status of bank loans,

the effective rate of interest being paid, compensating balances, and all other factors relating to the Corporation's ability to finance the tender offer and the payout to the minority stockholders on the "short form" merger. The remaining Directors were polled and, in view of the business considerations detailed by management, all concurred in the recommendation to proceed with the tender offer.

Mr. Sargent stated that, as he had noted earlier, on a Delaware "short form" merger, the minority are entitled to be paid the fair value of their shares, exclusive of any element of value arising from the merger. In the first instance the Corporation or the Board of the new subsidiary would set the price, and any UEC share holder objecting to the price could seek appraisal under Delaware law. He stated that management did not have a final recommendation on the price to be offered on the merger, but that he was certain that it would not exceed $50 a share and might be less.

Mr. Sargent stated that it was proposed that Chase Manhattan Bank be designated as Tender Agent, that Georgeson & Co. be retained to assist on the tender offer and that a fee of 50 cents a share be paid to soliciting brokers. He then submitted to the meeting the proposed Invitation for Tender and Form of Tender and Assignment. He stated that these documents were substantially as submitted and reviewed at the August Board meeting, except that UEC earnings data for the first nine months of the year had been included. He stated that the documents had also been cleared with the New York Stock Exchange. The Chairman

directed that copies of the proposed Invitation for Tender and Form of Tender and Assignment be filed with the records of the meeting.

Mr. Sargent stated that, in addition to authorizing the tender offer and related action, it would be appropriate at this time for the Board to authorize the management, in its discretion, to organize a new Delaware subsidiary, to transfer the UEC stock to such subsidiary and to take such other action as would be required to effect the "short form" merger on the basis proposed. He stated that it was expected that the definitive plan for the combination of UEC and Freeman would be developed in time to permit its consummation by the end of the year.

After further discussion, on motion duly made, seconded, and unanimously carried, it was

RESOLVED, that the Corporation make an offer (hereinafter in these resolutions called the Tender Offer) to purchase shares of Common Stock of The United Electric Coal Companies (hereinafter in these resolutions called UEC) by inviting tenders for such shares at a price of $50 per share in the manner and on the other terms set forth in the instruments hereinafter in these resolutions approved; and further

RESOLVED, that the form, terms and provisions of the proposed Invitation for Tenders and the proposed Form of Tender and Assignment to be used in connection with the Tender Offer, copies of which have been submitted to this meeting, be, and hereby are, approved, with such changes therein as the President or the Vice President-Finance of the Corporation and Counsel for the Corporation may deem necessary or advisable and approve; and further

RESOLVED, that The Chase Manhattan Bank, N.A., be, and hereby is, designated as Tender Agent of

the Corporation for the purposes of the Tender Offer; and further

RESOLVED, that the President, the Vice President-Finance or the Secretary of the Corporation be, and each of them hereby is, authorized to

(a) engage The Chase Manhattan Bank, N.A., as Tender Agent of the Corporation in connection with the Tender Offer;

(b) extend the termination date of the Tender Offer to such date (not later than November 21, 1968) as they or any of them shall determine;

(c) pay commissions or fees to brokers responsible for soliciting tenders of shares of Common Stock of UEC;

(d) retain solicitors to assist in connection with the Tender Offer;

(e) deliver to the Tender Agent such instructions as they or any of them shall deem necessary or proper in connection with the Tender Offer (which instructions shall designate the persons authorized to act for and on behalf of the Corporation in connection therewith); and

(f) take all such other action as they or any of them shall deem necessary, proper or advisable in connection with the Tender Offer and the implementation of these resolutions or any of them; and further

RESOLVED, that the President, the Vice President-Finance, or the Secretary of the Corporation be, and each of them hereby is, authorized to take all such action, in the name and on behalf of the Corporation, as shall be necessary or proper to

(a) at such time as the Corporation shall own not less than 90% of the outstanding stock of UEC, cause UEC to be merged into the Corporation and, in connection therewith, set the terms and conditions of the merger (provided that the consideration to be paid for shares of UEC shall not exceed $50 a share) and execute and file a certificate of ownership and merger, all in accordance with Section 253 of the Delaware General Corporation Law;

(b) form a new corporation under the laws of the State of Delaware (hereinafter called New Corporation);

(c) execute, in the name and on behalf of the Corporation, a subscription agreement with New Corporation providing for the purchase by the Corporation of all the authorized capital stock of New Corporation for not more than $1000;

(d) as an alternative to the actions authorized pursuant to (a) above, transfer to New Corporation, as a capital contribution, all the shares of Common Stock of UEC owned by the Corporation (including, but not limited to, the shares of Common Stock of UEC to be purchased by the Corporation pursuant to the Tender Offer); and

(e) at such time as New Corporation shall own not less than 90% of the outstanding stock of UEC, cause UEC to be merged with and into New Corporation in accordance with Section 253 of the Delaware General Corporation Law upon such terms and conditions as said officers or any of them shall deem advisable, and in connection therewith to cause the Corporation to advance to New Corporation such funds as may be necessary to enable New Corporation to effect the terms of said merger.

THE UNITED ELECTRIC COAL COMPANIES DX 113

Special Meeting of the Board of Directors

October 9, 1959

A special meeting of the Board of Directors of

THE UNITED ELECTRIC COAL COMPANIES

was held at the office of the Company, 307 North Michigan Avenue, Chicago, Illinois, on the 9th day of October, 1959, at ten o'clock A. M., Central Daylight Saving Time, pursuant to waiver of notice.

The following directors were present:

John D. Ames
Dudley F. Jessopp
Frank F. Kolbe
John E. Martin
J. M. Morris

constituting a majority of the Board and a quorum.

Absent: Paul C. Clovis
J. Sterling Rockefeller
Henry A. Rudkin
George Spatta

The meeting was called to order by the President, Mr. Frank F. Kolbe, who presided throughout as Chairman of the meeting, and the minutes were recorded by Mr. G. H. Utterback, Secretary of the Company.

The Chairman suggested to the Board that a consideration of the minutes of the meeting of the Board of Directors held on September 21, 1959, be postponed to a later date.

The President then stated that certain large stockholders of the Company whose stock holdings aggregated approximately 50% of the Company's shares were requesting representation on the Board of Directors. He said that in the past he had offered representation

to them but that they had declined. He further stated that in order to meet such current request it would be necessary to eliminate five members of the present Board. He stated that the members of the present Board had agreed among themselves that Messrs. Frank F. Kolbe, J. M. Morris, John D. Ames and Dudley F. Jessopp should remain on the present Board, and that Messrs. Frank Nugent, Milton Falkoff, Reuben Thorson, Irving Crown and Barton R. Gebhart should be the other five nominees to be suggested by the management, and that a proxy statement should be issued by the management to solicit proxies for the election of such nine suggested nominees.

Thereupon, on motion duly made by Mr. Jessopp, and duly seconded by Mr. Ames, it was unanimously

RESOLVED, that the action taken by this Board of Directors at its meeting held on July 10, 1959, authorizing the Secretary of this Company to mail to stockholders of record on September 30, 1959, a notice and proxy statement in the forms adopted at said meeting and a proxy naming Messrs. Rudkin, Ames and Kolbe as proxies therein, be and the same hereby is rescinded.

FURTHER RESOLVED, that the Secretary of this Company be and he hereby is authorized and directed to cause the Transfer Agent for the common stock of this Company to mail as soon as reasonably possible after the date of this meeting, in accordance with the By-laws of this Company and the laws of the State of Delaware, to all stockholders of record as of the close of business September 30, 1959, addressed to them at their respective addresses as they appear on the books of this Company, a notice and proxy statement in substantially the following forms:

EXCERPTS FROM MINUTES OF
MEETINGS of May 13, 1960

The Chairman brought up for discussion the Company's ownership in McDonough and Schuyler Counties. At July 31, 1959 the Company owned or had contracts to purchase 2,529.10 acres of coal containing an estimated 8,976,117 tons and as of this date these figures have been increased to 3,339 acres of coal containing 11,530,000 tons. Inasmuch as the development of this field is probably some ten years in the future, it was decided not to pursue an aggressive purchasing policy in that area, but only to acquire acreage which might become available at not to exceed normal farmland prices in this area.

EXCERPT FROM MINUTES OF
MEETING OF JULY 15, 1960

Mr. Hepburn was invited into the meeting and, referring to a map that displayed the western part of Illinois, explained the Company's plan for acquiring #2 coal reserves in McDonough and Schuyler Counties where some 10,000,000 tons are already held in reserve. He stated that about a year ago a mining feasibility study was made of the property. A study of County records discloses that coal land options are being taken by two or three other companies. It was decided to review and revise the feasibility study to re-examine the advisability of pursuing a more active optioning program in the area.

than for any previous month. All mines were in good physical condition, with Fidelity being particularly improved by the new location with lower ratio and better stripping conditions in general. Banner Mine produced 38,47h tons and changes in the washing plant are still in progress.

Increased sales were due largely to greater purchases by power companies, particularly Commonwealth Edison and Illinois Power.

Some additional strip coal found at Mary Moore Mine, while of higher stripping ratio, will make it possible to keep the mine in operation for another 6 or 8 months and this is being considered.

The President stated that the Company is continuing to take options and leases on coal in the Beaucoup Field, acting as agent for the Aluminum Company of America. At a recent meeting officials of Alcoa indicated they planned to make the next expansion so as to use the coal reserve in Beaucoup Field. The total reserve is considerably greater than the 100 million tons allocated as a proper backlog for aluminum production and the officials expressed an interest in the possible development of a coal mine in the area prior to the need for an aluminum plant, the coal so produced to be sold in the industrial market when and if such a demand is forthcoming. Mr. Nugent stated that the engineers for Freeman Coal Mining Company could make a feasibility study for such a project when necessary.

There being no further business, on motion duly made by Mr. Jessopp, and duly seconded by Mr. Morris, the meeting was adjourned.

[illegible]
Secretary

(c) To consult with the Auditors regarding the scope of the audit to be made by such Auditors and to determine other services to be rendered by such Auditors with respect to such audit and other affairs of the Company.

(d) From time to time to advise this Board in respect of the matters herein covered, and

(e) To exercise such other powers as from time to time shall be delegated to it by the Board and as shall be necessary or proper to make effective the provisions of this resolution.

FURTHER RESOLVED, that Mr. Milton Falkoff be and he hereby is designated the Chairman of said Committee.

Upon motion duly made by Mr. Nugent, and duly seconded by Mr. Falkoff, it was unanimously

RESOLVED, that the proper officers of this Company, for and on its behalf, be and they hereby are authorized and directed to place a purchase order for a 70 cubic yard stripping shovel costing approximately $2,800,000.00; and

FURTHER RESOLVED, that said order be subject to cancellation within 30 days from this date by payment of such expenditures as the manufacturer may have made during that time and which cannot be recouped by him.

The Chairman stated because of conversations in the past in regard to possible consolidation with another coal company in this area it might be well to give some consideration to the subject.

Thereupon, on motion duly made by Mr. Gebhart, and duly seconded by Mr. Thorson, Messrs. Nugent, Falkoff and Morris not voting, it was

RESOLVED, that a committee composed of Messrs. Nugent as Chairman, Falkoff and Morris be and they hereby are appointed to serve at the pleasure of this Board to investigate and report to this Board concerning such consolidation.

Mr. Morris reported that Midwest Towing Co., Inc. for the first nine months of 1960 had a net income of $71,516.00 as against $44,235.00 for the corresponding period in 1959. Revenue for this

Excerpt FROM MINUTES OF MEETING OF MARCH 10, 19(

Upon motion duly made by Mr. Nugent, and duly seconded by Mr. Ames, the following preambles and resolution were unanimously adopted:

> WHEREAS, this Company on January 31, 1961 conveyed by Deed of Conveyance to James C. Sneed approximately 3½ acres of land in Hopkins County, Kentucky, the total consideration being $2,500.00; and
>
> WHEREAS, this Company completed its mining operations in this area some years ago and has no further use for the land;
>
> NOW, THEREFORE, BE IT RESOLVED, that the action of the officers of this Company, for and on its behalf, in executing said Deed of Conveyance to James C. Sneed, upon the terms as set forth above, be and the same hereby is in all respects approved, ratified and confirmed.

Upon motion duly made by Mr. Nugent, and duly seconded by Mr. Crown, the following preambles and resolution were unanimously adopted:

> WHEREAS, the proper officers of this Company on Jan. 27, 1961 entered into a coal lease with A. E. Gross and Margaret Gross covering the acquisition of minerals and the right to use the surface of approximately 12 acres of land in Vermilion County, Illinois, containing an estimated 95,600 tons of coal, the consideration being 27¢ per ton on the first 50,000 tons and 2¢ per ton on all over 50,000 tons, with advance royalty of $13,500.00, payable $7,000.00 on January 27, 1961, and $6,500.00 on August 1, 1961; and
>
> WHEREAS, at a stripping ratio of about 12 to 1 there is an estimated mineable tonnage of 38,300 which at the minimum royalty of $13,500.00 will cost 35.3¢ per ton; and
>
> WHEREAS, the acreage covered by the lease is necessary for proper continuous operation of the Mary Moore Mine;
>
> NOW, THEREFORE, BE IT RESOLVED, that the action of the officers of this Company, for and on its behalf, in entering into the coal lease with A. E. Gross and Margaret Gross, upon the terms and conditions as set forth above, be and the same hereby is in all respects approved, ratified and confirmed.

Mr. Nugent raised the question of the Company's reserves of mineable strip coal. After considerable discussion, upon motion duly made and duly seconded, it was

RESOLVED, that Messrs. Frank Nugent, John Morris and Irving Croun be and they hereby are constituted a committee to study the Company's situation in regard to reserves and to make recommendations to the Board as to how further reserves should be acquired.

FURTHER RESOLVED, that Mr. Frank Nugent be and he hereby is delegated to serve as Chairman of such Committee.

In view of the fact that March is the second month of the third quarter of the fiscal year, Mr. Morris brought up for discussion the Management Incentive Bonus for said fiscal year, and it was decided to defer discussion on this subject until the Board meeting scheduled for May 12th.

Mr. Morris also raised the question as to whether it would be advisable to transfer to a Chicago bank the Trusteeship of The United Electric Coal Companies Employees' Profit Sharing Trust fund from The Chase Manhattan Bank in New York. The question was referred to Messrs. Falkoff and Jessopp to report back to the Board at its May 12th meeting.

Mr. Falkoff, Chairman of the Audit Committee, requested that, in view of Mr. Thorson's absence, the report of Haskins & Sells detailed audit for the year ended July 31, 1960 be deferred until the Board meeting scheduled for May 12th. Mr. Falkoff further requested that the appointment of auditors for the year ending July 31, 1961 be deferred until the Board meeting on May 12th.

Mr. Falkoff also recommended that in the future the detailed audit report be made available to the Audit Committee before the annual statement is approved for printing.

There being no further business, on motion duly made by Mr. Anes, and duly seconded by Mr. Morris, the meeting was adjourned.

Secretary

EXCERPT FROM MINUTES OF MEETING ON MAY 12, 1961.

5. When and if requested by United Electric, Central Illinois Light Company will use coal from this storage pile and United Electric may curtail shipments to that extent, and when requested by United Electric, Central Illinois Light Company will put into storage additional coal, and by this arrangement, United Electric will be able to ship at times most beneficial to production and sales commitments.

6. On coal withdrawn from storage at request of United Electric, 7¢ per ton will be charged for such withdrawal.

Previous contract provided for re-opening of price and annual tonnage each year and this new contract gives firm commitment on price and tonnage.

NOW, THEREFORE, BE IT RESOLVED, that the action of the officers of this Company, for and on its behalf, in entering into such contract with Central Illinois Light Company, upon the terms and conditions as set forth above, be and the same hereby is in all respects approved, ratified and confirmed.

Mr. Hepburn was invited into the meeting and he and Mr. Nugent made a report on the Company's stripping reserves, using maps of Fulton County and Perry County, showing the Company's reserve areas in relation to the reserve areas of other strip companies, and it has been determined that the present reserves provide tonnage for continuing and growing production for about fifteen to twenty years. After discussion, upon motion duly made by Mr. Nugent, and duly seconded by Mr. Thorson, it was unanimously

RESOLVED, that the proper officers of this Company, for and on its behalf, be and they hereby are authorized and directed to begin at once an aggressive program to option for purchase and/or lease areas for test drilling in the North Canton and South Buckheart areas in Fulton County, and in the area in Perry County and Jackson County immediately south of the property acquired from Union Colliery Company.

The President reported to the Board that the new Bucyrus-Erie 70-yard stripping shovel was expected to be delivered and in operation at Fidelity Mine sometime late in the current year. This machine was

EXCERPT FROM MINUTES OF MEETING ON SEPTEMBER 8, 1961

The Chairman recalled that at a meeting of the Board held on July 14, 1961, a resolution was adopted authorizing the sale of a tract of 174 acres at Mary Moore Mine, said authorization subject to appraised value being obtained. The President then reported that an appraisal was obtained from a bank in Danville, Illinois, the value being set at $50,000 cash, or possibly $70,000 if sold by contract. Another appraisal was obtained from a Peoria appraisal firm which established the market value at $65,000. Since the price offered by the prospective purchaser, Miels C. Nielsen, was $85,000, the sale will be made to him, the purchase price to be paid as follows: $25,000 on signing of contract, $20,000 on each of the three next successive anniversaries, with interest on the unpaid balan at 5% per annum. However, Mr. Nielsen has agreed to purchase certain small tracts adjacent to the 174 acres that will eliminate the need for the Company to remove a haulage road and construct a private bridge, thus saving the Company an estimated $12,000 to $15,000, and consummation of the sale is contingent on Mr. Nielsen so doing.

In regard to the annual report for the fiscal year ended July 31, 1961, a draft of the letter to stockholders and a review of the results were read. It was pointed out by the President that in previous years only the coal deposits suitable for strip mining were included in our annual report. After considerable discussion it was decided that total coal deposits, both strip and underground, owned and controlled by the Company be shown in the annual report.

Upon motion duly made by Mr. Nugent, and duly seconded by Mr. Thorson, the following preamble and resolution were unanimously adopted:

> WHEREAS, the proper officers of this Company expended certain sums for equipment for use at its various mines as follows:

and

WHEREAS, the resolutions authorizing and/or approving said coal mining leases did not state that the acquisition of minerals included also "the right to use the surface" for such purposes as may be necessary in carrying on the strip mining operations; and

WHEREAS, such right is included in the coal mining leases;

NOW, THEREFORE, BE IT RESOLVED, that the wording of the resolutions authorizing and/or approving the six coal mining leases cited in the foregoing preamble should include the phrase "the right to use the surface", and that said phrase be and the same is hereby made a part of each of the cited resolutions the same as if it had been included in the original resolutions.

Mr. Nugent, Chairman of the Land Committee, referred to the coal land reserve position of the Company and the need to add to the operating life of present mines. The Company should continue to pursue a vigorous land acquisition program, not only at existing properties but at any location that might provide additional reserves and extension of mining activities. Management was again instructed to pursue this policy in acquiring additional coal lands suitable either for strip or underground mining.

Upon motion duly made by Mr. Crown, and duly seconded by Mr. Nugent, the following preamble and resolution were unanimously adopted:

WHEREAS, the proper officers of this Company expended the sum of $66,331.20 for the purchase of 1 Northwest 80-D coal loading shovel for use at Banner Mine;

NOW, THEREFORE, BE IT RESOLVED, that the action of the officers of this Company, for and on its behalf, in expending the sum of $66,331.20 for equipment as set forth above, be and the same hereby is in all respects approved, ratified and confirmed.

The Chairman advised that Midcontinent Barge Company, which Company is owned jointly with Truax-Traer Coal Company, desired to

purchase six 1,500 ton barges to take care of the increase in coal shipments on the Mississippi River. The Chairman further stated that Ingalls Ship Building Company has for sale six new barges, just recently completed, and of the type now in use by Midcontinent Barge Company. The purchase price of the Ingalls' barges is $60,000 per barge as compared with $61,500 and $63,900 per barge quoted by two other builders, neither of which could make immediate delivery.

At a meeting held on May 15, 1962, the Executive Committee authorized this Company, as a stockholder in Midcontinent Barge Company, to approve the purchase of the six barges, and that this Company purchase 1,000 shares of the no par value capital stock of the Barge Company for $150,000, the proceeds of such stock to be used toward completion of such purchase of barges. The 1,000 shares would continue to represent this Company's 50% share of the capital stock of such Barge Company.

After discussion, on motion duly made by Mr. Ames, and duly seconded by Mr. Thorson, the following preambles and resolution were unanimously adopted:

> WHEREAS, the Executive Committee of the Board of Directors of this Company at a meeting held on May 15, 1962, authorized the purchase of 1,000 shares of Midcontinent Barge Company's no par value capital stock, being the allocable portion of this Company's interest in such Barge Company, at a price of $150,000, on the determination that such $150,000, together with other available monies, will be used to purchase six 1,500 ton capacity barges by Midcontinent Barge Company, and also approved the authorization by this Company of making such purchase of barges; and
>
> WHEREAS, Midcontinent Barge Company has authorized the issuance of such shares to this Company; and
>
> WHEREAS, the Continental Illinois National Bank and Trust Company of Chicago and The Chase Manhattan Bank have agreed in writing that the expenditure of such money for the purchase of stock of Midcontinent Barge

EXCERPT FROM MINUTES OF MEETING ON JULY 13, 1962

The Chairman then presented a resolution approving this Company's action in signing a coal lease with United States Steel Corporation under which the life of Mary Moore Mine would be extended some four years.

After discussion, upon motion duly made by Mr. Crown, and duly seconded by Mr. Thorson, the following preamble and resolution were unanimously adopted:

> WHEREAS, the proper officers of this Company on June 28, 1962 entered into a lease with United States Steel Corporation covering the acquisition of all of the coal of the #7 vein and the right to mine the same on approximately 111 acres in Vermilion County, Illinois, containing an estimated 645,000 tons of the #7 vein, the consideration being 15¢ per ton royalty with minimum royalty of $60,000, payable $6,000 on January 10, 1963 and $6,000 per year on each of the succeeding nine anniversary dates;
>
> NOW, THEREFORE, BE IT RESOLVED, that the action of the officers of this Company, for and on its behalf, in entering into the coal lease with United States Steel Corporation, upon the terms and conditions as set forth above, be and the same hereby is in all respects approved, ratified and confirmed.

Upon motion duly made by Mr. Crown, and duly seconded by Mr. Thorson, the following preambles and resolution were unanimously adopted:

> WHEREAS, the proper officers of this Company on June 28, 1962 entered into a lease with United States Steel Corporation under the terms of which this Company acquired the right to mine all of the coal contained in the #7 vein on certain premises in Vermilion County, Illinois; and
>
> WHEREAS, Karl Zamberletti and Frances Zamberletti, co-partners doing business as V-Day Coal Company, on October 14, 1960 entered into a lease with United States Steel Corporation under the terms of which V-Day Coal Company acquired the right to mine all of the coal contained in the #6 vein on certain premises in Vermilion County, Illinois; and
>
> WHEREAS, the premises containing the #6 vein leased to V-Day Coal Company are identical with the premises containing the #7 vein leased to this Company; and
>
> WHEREAS, the #6 vein underlies the #7 vein, being separated from same by some 40 feet; and

4196

EXCERPT FROM UEC BD. MEETING MARCH 8, 1963

WHEREAS, Midwest Towing Co. Inc., owned jointly by this Company and another coal company, experienced a decrease in revenue received from its winter operations on the Ohio River largely because of bad weather and inoperable river conditions; and

WHEREAS, Midwest Towing Co. Inc. needs working capital to operate on the Mississippi River during the summer months;

NOW, THEREFORE, BE IT RESOLVED, that the proper officers of this Company be and they hereby are authorized to lend to Midwest Towing Co. Inc. an amount not to exceed $75,000 for a period of three months, secured by a promissory note executed by the proper officers of Midwest Towing Co. Inc.;

FURTHER RESOLVED, that should the amount lent to Midwest Towing Co. Inc. exceed $50,000, approval to make such loan will be obtained from the Continental Illinois National Bank and Trust Company of Chicago, representing the lending banks under this Company's loan agreement dated September 1, 1961.

Opening a general discussion on the question of mineable reserves the President stated that at Buckheart the total possible including present operating area, North Canton and South Buckheart would amount to some 46,600,000 tons, most of which have been acquired or optioned. At Cuba Mine possibly 1,500,000 tons of #6 are available although not yet acquired; possibly 3,500,000 to 5,000,000 tons of #2, some of which is under option, and all of which is high ratio stripping; making a possible estimated total of 7,000,000 or 8,000,000 tons for the Cuba plant.

In the northwest part of Fidelity field there are some estimated 4,000,000 additional tons that will be added, bringing the estimated total to about 28,000,000 tons.

In the face of the obvious limits in strip tonnage available in the vicinity of the Company's properties now being mined a study is being undertaken to determine as nearly as possible all of the strippable reserves in Illinois, Indiana, West Kentucky and Missouri, and by what method such reserves can be acquired.

and arrangements have been made to do this.

After discussion, upon motion duly made by Mr. Gebhart, and duly seconded by Mr. Falkoff, the following preamble and resolution were unanimously adopted:

> WHEREAS, this Company plans to purchase from Truax-Traer Coal Company approximately 83 acres of land in Perry County, Illinois, containing an estimated 600,000 tons of coal, the total consideration being $16,191.06;
>
> NOW, THEREFORE, BE IT RESOLVED, that the proper officers of this Company, for and on its behalf, be and they hereby are authorized and directed to purchase said tract from Truax-Traer Coal Company, upon the terms as set forth above.

The Chairman reported on the Company's activities in acquiring stripping reserves in Colorado. On prospecting permits acquired from the Federal Government preliminary drilling indicates some 18,000,000 tons of strippable coal with perhaps additional tonnage available when a more complete drilling program is undertaken. This tonnage is located in Routt County near Hayden where Colorado Ute Electric Association is building a steam generating plant, the initial capacity to be 225 megawatts with additional units being planned for future expansion. This Company is also attempting to acquire both strip and underground reserves in west central Colorado near Grand Junction where the Public Service Company of Colorado operates a steam generating plant.

In Illinois this Company's reserves increased 5,000,000 tons over production for the year ended July 31, 1963.

The proposed President's letter and a report (Review of the Year) for the annual report for the year ended July 31, 1963, were discussed and approved as to substance as drafted.

The Chairman then stated that the next order of business was

BOARD OF DIRECTORS MEETING HELD MAY 8, 1963

The Chairman informed the Board that the Company had acquired an option to purchase 372 acres of land in McDonough and Schuyler Counties, Illinois (Industry Field) at a price of $170 per acre containing an estimated 600,000 tons of strippable coal. It was brought out in discussion that recent changes in transportation costs and improvement in underground mining cost place the Industry Field in a somewhat doubtful position in planning a stripping development on this acreage. Land acquisitions in this area have been limited to purchases or leases which can be made at approximately farmland prices. The land in question is adjacent to the other acreage that makes up the main body of the Industry Field and will fit into any future requirements for development. The area is being actively farmed and pastured by the Company at present.

After the above discussion, upon motion duly made by Mr. Nugent and duly seconded by Mr. Thorson, the following preamble and resolution were unanimously adopted:

> WHEREAS, the proper officers of this Company on December 2, 1963 entered into an Option with Contract to Purchase with John C. Stoneking and Bessie M. Stoneking, covering the purchase of approximately 372 acres of land in McDonough and Schuyler Counties, Illinois (Industry Field), containing an estimated 600,000 tons of coal, at a price of $63,240.00, payable $240.00 on execution of contract, and $9,000.00 per year for seven years, which agreement contains the usual provision that this Company may terminate it at any time by forfeiture of the payments previously made;
>
> NOW, THEREFORE, BE IT RESOLVED, that the proper officers of this Company, for and on its behalf, be and they hereby are authorized and directed to exercise said option with John C. Stoneking and Bessie M. Stoneking upon the terms and conditions as set forth above.

EXCERPT FROM UEC BOARD MEETING AUGUST 12, 1966

Mr. Morris outlined the need for additional stripping equipment at the Fidelity Mine. Present equipment will maintain current production rate in the present pit for approximately eighteen months, at which time, with deeper overburden, the 1650-B would need help to maintain production of approximately 180,000 tons per month.

After mining all of the coal in the present location (Green Pit), the estimated reserves at Fidelity that can be stripped is 23,000,000 tons. This is located in three different areas and shows overburden depths, rock and surface material that would require a machine to help the 1650-B to mine it all out economically. Without a helper, monthly production would be reduced from its current rate of 180,000 tons to approximately 125,000 tons, with resultant cost increase. Also, of this 23,000,000 tons, approximately 10,000,000 could not be mined at all with the one machine (1650-B). The need for additional help is thus established as necessary.

Mr. Morris stated that after thorough investigation, a wheel, properly designed for the particular areas involved, seemed to be the best solution.

The following information and estimates have been developed.

1. Bucyrus-Erie has a standard design and has built a wheel for Peabody and one for Truax. It is high enough for us, but for our purpose certain modifications of design seem necessary. They put a price on their standard dsign of $2,500,000, and an estimate on transportation and erection of $400,000.

While we don't know exactly what the change in design we would need would cost, they have indicated that the engineering and other factors involved would cost somewhere in the neighborhood of another $400,000. So it appears we are thinking about something over $3,000,000 for a Bucyrus machine properly designed and in place, ready to operate.

2. We have built four wheels, three of which are now in operation. The W-2 is at Buckheart, the W-3 at Banner, and the W-4 at Cuba. The W-3 was originally at Fidelity Mine but the design of this particular machine did not properly serve the need at that mine and it was not successful there. It was redesigned and moved to Banner and our cost and profit record there will indicate its satisfactory performance.

   The wheels at both Buckheart and Cuba are doing a satisfactory job.

3. We have all of the engineering information and blue prints necessary to build the type of wheel we need at Fidelity. This is quite a cost saving.

   The machine would be built higher, the digging end longer, and the stacker end some longer and higher to place the dirt back far enough in deep overburden to avoid slides. We would use the base, motors and quite a lot of other material from the 5561 Marion shovel which is now a stand-by at Fidelity.

4. Utilizing our engineering knowledge, blue prints, and experience, and building the machine on the site, would effect considerable savings. The repair parts in inventory for the 5561 and also repair parts in inventory for Wheels 2, 3 and 4 would be available for the W-5 machine.

5. Our estimate of the total cost, using our own people for the engineering and supervision, and contracting for the welding, erection and so forth, is $1,600,000.

We feel our estimates are within reason and have included in the above figure $200,000 for contingencies and unexpected difficulties.

In our five-year budget for capital expenditures, we included $250,000 in 1966 and $1,750,000 in 1967.

We can build this machine and have it in operation within fourteen months. The best estimate from Bucyrus is eighteen months and probably longer.

After discussion, upon motion duly made by Mr. Nugent, and duly seconded by Mr. Thorson, the following resolution was unanimously adopted:

RESOLVED, that management be authorized to proceed with the necessary purchasing and contractual arrangements to build Wheel No. 5 for use at the Fidelity Mine at a cost of not to exceed $1,800,000.

EXHIBIT "A"

DX 114

THE UNITED ELECTRIC COAL COMPANIES

NOTICE OF ANNUAL MEETING OF STOCKHOLDERS

Notice is hereby given that the Annual Meeting of the Stockholders of The United Electric Coal Companies will be held at the office of the Company, 307 North Michigan Avenue, Chicago, Illinois, on Friday, October 29, 1954, at 10:30 A.M. Central Standard Time, for the purposes of electing a Board of eleven (11) Directors to serve until the next Annual Meeting of Stockholders and until their successors are elected and qualified, and of transacting such other business as may properly come before the Meeting.

The Board of Directors has fixed the close of business on September 29, 1954, as the record date for the determination of stockholders entitled to notice of and to vote at the Meeting.

If you do not expect to be present at the Meeting, please sign and mail the enclosed proxy in the return envelope provided for that purpose. No postage is required if mailed in the United States.

PROXY STATEMENT

1. The Annual Meeting of Stockholders. The Annual Meeting of the Stockholders of the Company will be held on October 29, 1954, pursuant to its By-laws for the purposes of electing a Board of eleven (11) Directors to serve until the next Annual Meeting of Stockholders and until their successors are elected and qualified, and of transacting such other business as may properly come before the Meeting. As of the date of this Proxy Statement the election of Directors is the only matter which the management intends to present or knows will be presented by others. Should any other matter properly come before the Meeting, it is the intention of the proxies named in the enclosed proxy to act upon it according to their best judgment.

2. The Proxy. Proxies in the form which is enclosed with this Notice and Proxy Statement are solicited by and on behalf of the management. When the proxy in such form is properly executed and returned the shares represented thereby will be voted at the Annual Meeting. Any stockholder giving a proxy in such form has the power to revoke it at any time prior to its being voted.

3. Voting Securities and Principal Holders thereof. As of September 29, 1954, the record date for stockholders entitled to notice of and to vote at the Meeting, the Company had 750,000 shares of common stock of $5 par value each authorized, of which 677,920 shares were issued and outstanding. Each stockholder has one vote for each share held. In the election of Directors, the holders of stock do not have cumulative voting rights.

As of July 31, 1954, Material Service Corporation owned beneficially 72,600 shares of common stock of the Company which shares represented approximately 10.7% of the outstanding voting securities of the Company on that date.

nuclear power briefing

for the COAL INDUSTRY

September 29-30, 1966
Oak Ridge, Tennessee

United States Atomic Energy Commission | Division of Technical Information

• • •

Nuclear Fuel Fabrication

by James H. Hill
Vice President, United Nuclear Corporation

It is a pleasure for me to be in Oak Ridge to participate in the nuclear power briefing for the Coal Industry. I notice that Dr. Weinberg is speaking this evening on the subject "Uranium and Coal - Partners or Rivals?". I suspect that he is going to suggest that we should be partners. In any event it is in that spirit that I accepted the invitation to be here.

The purpose of this paper is to present a brief account of the various steps in taking uranium from the earth and converting it into a finished reactor core for the production of central station electrical power. The details involved in "burning" uranium are somewhat more complex in comparison with the burning of coal. However, some of the complexity of the subject can be attributed to the nuclear jargon, mathematical equations, and chemical formulae which are commonly used in the industry. As far as fuel fabrication is concerned I think that it unfolds in fairly simple steps for discussion as follows:

Mining and Milling -
Conversion of U_3O_8 to UF_6
Enrichment of UF_6
Production of UO_2 and Pellets
Fuel Tube Loading - Welding and Assembly
Fuel Management
Market Development for Fuel Fabrication
Price Trends

I will limit my remarks to a brief discussion of each of these steps related to the fabrication of nuclear fuel for commercial power reactors.

Mining and Milling

First the uranium ore must be located, the ore body developed and then mined. A major portion of the mines and mills is located in New Mexico, others are located in Wyoming and Colorado. The ore is usually hauled to the mill in large trucks.

The purpose of the milling operation is to recover the U_3O_8 from the ore. The ore that is being mined today contains about four to five pounds of U_3O_8. The mill that I will describe is designed to process about 3,000 tons of ore per day by the alkaline leach-caustic soda precipitation method.

The first step in the milling operation is the crushing and screening of the ore in a closed circuit to produce a crushed product of less than half an inch in size. Some of the ores are wet and must be put through a rotating kiln-type dryer between the crusher and the screens. Next the ore is introduced into a ball mill grinding and classifier circuit in which it is reduced to the size of extremely fine sand. A slurry and solution of this finely ground ore is pumped to a large tank with slowly moving rakes

in the bottom. The ore slurry settles to the bottom and is t... umped to a leaching circuit where the uranium goes into solution by reaction with sodium carbonate. The uranium solution is separated from the worthless sands by filtration and is then reacted with sodium hydroxide. It precipitates as U_3O_8 which we call "yellowcake". The "yellowcake" is filtered from the slurry and heated in a furnace. Heating at about 1600°F converts the vanadium in the "yellowcake" to a water soluble compound. The hot material drops into a tank of water and the vanadium dissolves. The vanadium is sold as a by-product. Again the "yellowcake", now free of vanadium and assaying 86% uranium oxide, is filtered, dried, and packed in drums that contain 1,000 pounds of finished product ready for shipment. It takes about 4,000 to 5,000 tons of this material (U_3O_8) to fuel an 800 Mwe reactor over its thirty-year lifetime. The cost of the U_3O_8 is about 27% of the total cost of a reactor core.

Conversion of U_3O_8 to UF_6

The next step in fuel preparation is the conversion of U_3O_8 into UF_6, the feed material for the gaseous diffusion enrichment plants. Two conversion processes have been in general use in this country. The process used in the Government plants involves the removal of impurities from the U_3O_8 in nitric acid solution by an organic solvent extraction process. The resultant uranium oxide is hydrofluorinated and converted to a green powder called uranium tetrafluoride (UF_4) -- additional treatment with fluorine converts it to UF_6. The second method, used in industry, is more direct. It eliminates the solvent extraction step and carries the impurities through to the UF_6 phase where they are remove' by distillation.

The Government UF_6 plants and the Allied Chemical Company's UF_6 plant at Metropolis, Illinois have been shut down for over two years. Allied indicated recently that it is ready to resume operation. I expect that within the next few years other companies will participate in the business of converting U_3O_8 to UF_6.

The cost of conversion of U_3O_8 to UF_6 is about 5% of the total cost of a reactor core.

Enrichment of UF_6

After the U_3O_8 is converted to UF_6, it is shipped to one of the Government's three gaseous diffusion plants for enrichment. The natural uranium in the UF_6 feed contains 0.711% uranium-235, the fissionable isotope. It has to be enriched to about 3% for use in the types of reactors that are being built today.

Prior to 1964, enriched uranium could be owned only by the Government but it could be leased at 4-3/4% interest for private licensed uses. Since the passage of the Private Ownership Act of 1964, it can be either purchased or leased. The purchase price is based on full recovery of Government costs -- $8 per pound for U_3O_8 and $30 per kg unit of separative work in the enrichment service. Beginning in 1969, it will be possible to produce or purchase U_3O_8 at competitive prices, convert it to UF_6 and have

it enriched in the Government's plant by paying the $30/kg separative unit tolling charge.

Two products emerge from the diffusion plant. One with an increased content of fissionable material and one with a decreased content. The enriched material is the fuel; the depleted material is called "tails". The owner of the material will have the option of giving up title to the depleted material or of taking it by paying handling and shipping charges. Someday these tails probably will be valuable as fuel for breeder reactors but today they have little value.

The cost of enrichment is about 32% of the total cost of a reactor core.

Production of UO_2 and Pellets

The next step in nuclear fuel fabrication is to convert the enriched UF_6 into the proper chemical and physical form required in the final reactor core. Pressurized Water Reactors (PWR) and Boiling Water Reactors (BWR) require about the same amount of basic fuel material (U_3O_8) per megawatt of capacity over a thirty-year plant life. Both are fueled with pellets of UO_2 and now the trend is for both to use zirconium fuel tubes. There the similarity in fuel ends. A typical high power PWR uses an initial loading of about 220,000 pounds of UO_2 pellets that are about .30 inch in diameter. A typical high power BWR uses an initial loading of about 360,000 pounds of UO_2 pellets that are about .50 inch in diameter. The initial loading for the BWR is larger than the PWR because the enrichment is lower. However, the PWR requires the production of about twice as many pellets per pound of UO_2 because of the difference in pellet diameter.

The chemical and physical operations required in the production of UO_2 pellets are complicated only by restrictions on equipment and procedures imposed by criticality and health physics considerations.

The conversion of enriched UF_6 to UO_2 is generally accomplished by either the "ammonium diuranate" (ADU) process or by the "organic reduction" process. The differences in these two processes occur primarily in their first steps in converting UF_6 into a stable solid compound suitable for further processing.

In the "ADU" process gaseous UF_6 is introduced into a solution of ammonium hydroxide. This forms a stable solid compound, ammonium diuranate. The ADU is separated by filtration and dried, then converted to UO_2 powder by heating to red heat in the presence of steam and hydrogen.

The "organic reduction" process begins with introduction of gaseous UF_6 into a vessel containing an organic reducing agent. The UF_6 is converted to UF_4, a stable compound commonly known as greensalt. The UF_4 is then converted to UO_2 powder by a reaction with steam and hydrogen.

The UO_2 prepared by either of these processes is in the correct chemical form for reactor use but is much too bulky. To reduce the bulk,

it is pressed into cylindrical pellets. Normally a press feed preparation step is required to give the bulky UO_2 powder better flow characteristics prior to entry into the die cavity of the press. This step produces a granular feed by means of agglomerating the powder with a wax binder. After pressing, the pellets are sintered in high temperature furnaces to form a high density ceramic body. The sintered pellets are then centerless-ground to obtain a finished diameter to a ± 5/10,000 of an inch specification and are made up into stacks for loading into fuel tubes.

Fuel Tube Loading - Welding and Assembly

The loading of pellets into zirconium tubes is a rather straightforward operation. The zirconium tubes are about 144 inches long. A large power reactor requires about 450,000 feet or 85 miles of tubes or between 40,000 and 75,000 pounds of zirconium depending upon tube wall thickness.

After the pellets are loaded in the tubes, end caps are welded to seal the pellets inside the tubes in an inert atmosphere. At this point we refer to the product as fuel rods. It takes about 35,000 to 40,000 fuel rods per reactor core for a large plant. The fuel rods are assembled into bundles with appropriate spacers and structures for holding them in a fixed position within the reactor core. An individual fuel assembly for a BWR will contain about 49 fuel rods. An assembly for a PWR will contain about 225 rods. In the BWR the fuel assembly is enclosed in a zirconium can or shroud to accommodate cruciform-type control rods which fit in between each group of four assemblies. The PWR does not use a shroud and present design incorporates control rods in place of fuel rods in selected positions in the assembly. The control rods in both types are needed to regulate the rate of energy production.

The fuel assemblies and control rods combined form the complete reactor core. When the core is placed in the reactor pressure vessel, similar in principle to placing an immersion heater in a teapot, you have "instant" power available -- all you have to do is add water. When the control rods are withdrawn nuclear fission begins (the uranium-235 is "burned") and heat is created which produces steam to drive the turbine-generator system which produces electrical power.

The fabrication cost component, which includes the cost of the zirconium tubes and the production of UO_2 powder and pellets, represents about 36% of the total cost of a reactor core.

Fuel Management

The objective of fuel management is to achieve safe operation and minimum power generation costs. Once the reactor core design has been established fuel management begins. The finished fuel assemblies are checked to verify that the quantities and distribution of uranium-235 meet design specifications. This provides a "bench mark" for subsequent calculations and operational instructions specifying the exact positions or withdrawal patterns in which the control rods should be operated. The maximum power peak position in the core is calculated as a function of control rod position. This is compared with the maximum heat flux that can be tolerated.

The control rod pattern is programmed so that maximum power removal can be achieved without damaging the fuel rods. Power distribution calculations are made on a continuing basis to maintain a precise record of how much enriched uranium has been "burned" in each fuel element and how much plutonium has been produced. The fuel managers thus can identify which fuel assemblies should be removed for reprocessing and the proper location for the addition of new fuel. This type of information supports the selection of a refueling scheme or change in design to yield maximum "burning" of the fuel consistent with minimum fuel cycle costs.

Market Development for Fuel Fabrication

Some special problems face the fuel fabricators and electrical utilities in the replacement core aspect of the business. The utility industry has recognized the need for obtaining competition for its fuel supplies. In the beginning utilities purchased one or two cores from the nuclear power plant manufacturer, with options for future reloads. This did not assure competition on future fuel supply. It is in the nature of reactor core performance, however, that the calculated data and data obtained during operation have to be carefully reviewed and assimilated in order to provide a reasonable set of specifications on which a fuel supplier can bid. Unless the utility company obtains these data, competitive fuel suppliers are placed at a severe disadvantage.

One of the ways utilities can assure competition is to take steps during the initial contract negotiations to insure the availability of sufficient drawings, specifications, operational and performance data to permit competitive bidding on future fuel supplies. If the utility company desires firm warranties for future fuel loadings, then detailed drawings, including materials, dimensions and tolerances, especially as they relate to mating with existing reactor or plant components such as grid structures, handling tools, etc., should also be provided. The detailed operating history of the original fuel and control rods, including burnups, isotopic compositions, power patterns, etc., should be made available to permit the competitive fuel supplier to predict performance of his fuel as related to the initial fuel remaining in the reactor. Water chemistry, corrosion data on materials in the coolant circuit, and thermal-hydraulic performance of existing fuel are also necessary to assure compatibility with replacement fuel.

By effectively requiring this type of information, utilities will be in a position to obtain competitive bidding for replacement fuel from companies other than the initial reactor supplier during the life of the plant. Perhaps an easier way that utilities could assure competition for replacement cores would be to require the reactor manufacturer to procure the equivalent of a reload batch of its initial fuel assemblies under subcontract to a fuel fabricator.

Price Trends

I have taken the liberty of discussing some of the problems that are being encountered by utilities and the nuclear industry as the market develops. I realize that through all of this the subject in which you are

most interested is the future price trend of nuclear power. Only from that can you better appraise the competition that the coal industry faces from nuclear power.

Beginning with the announcement in 1963 that the Jersey Central power plant at Oyster Creek would be nuclear, the electrical utilities have contracted for about 19,000 Mwe installed nuclear capacity in 27 plants. They have announced plans for an additional 6,500 Mwe in 9 plants for a total of about 25,500 Mwe. This does not include the nuclear capacity of about 1,400 Mwe in 15 plants announced, in operation or under construction prior to 1963, nor does it include the prospects for an additional 11 plants expected to be announced within the next year with an additional capacity of about 7,000 Mwe. By 1970 over 11,000 Mwe will be in operation increasing to about 50,000 Mwe in 1975 and to more than 100,000 Mwe by 1980. At that point one out of three new plants may be nuclear.

Some predict that fuel cycle costs will decrease from around two mills per kilowatt-hour for plants operating in 1970 to one mill per kilowatt-hour in 1980. Assuming that the average cost of fuel is 1.5 mills per kilowatt-hour over the thirty-year life of the large plants announced since 1963, the total fuel cycle cost over the life of these plants would be about $8.0 billion. Assuming an initial capital cost of installation of $110 per kilowatt the fuel cycle cost over the life of the plant is almost three times the initial capital cost.

This serves to illustrate two important points. The incentive for further reducing fuel cycle costs by new developments, and the incentive for effective competition in that portion of the business that is really big -- fuel replacement.

It is difficult to predict price trends because of the many variables involved. New processes are under development in industry to produce UO_2 powder with consistent characteristics at reduced costs. Further automation in the production and handling of pellets will reduce costs. The most significant accomplishment in reducing fabrication costs will be the development of a process for obtaining an acceptable fuel element by loading UO_2 powder directly into the fuel tube by vibratory compaction or some other method to avoid the production and handling of the millions of UO_2 pellets required in a core.

An important area for decreases in fuel cycle cost is in the improvement in "burnup" or power generating lifetime of the fuel. The extent of "burnup" is not basically limited by materials because there are design alternatives to solve some of the problems, such as swelling of the fuel due to buildup of fission product gases. The basic limitation is in the control of reactivity of the core and its relation to overall economics. In other words, to achieve longer lifetime and more efficient use of the fuel, considerably more enriched uranium must be added to the core than is necessary to sustain operation in the initial stages. This excess uranium is controlled by adding a burnable poison such as boron. Thus a larger inventory of enriched uranium would have to be financed throughout the entire operation. An economic balance has to be struck between this added cost of financing and the reduction in cost due to longer life of the fuel.

When we start recycling plutonium in replacement cores, this problem will be alleviated to some extent because the plutonium will contain up to 20% plutonium-240. This is an isotope that serves as a poison, similar to boron, in the early life of the reactor by absorbing neutrons. It not only burns out as a poison but converts to plutonium-241, a fissionable isotope which in effect replaces fuel "in situ". I think burnup can be increased by several thousand megawatt days per ton with a decrease in power cost of around 0.1-0.2 mills per kilowatt hour. This could mean a reduction in fuel cost of about $40 million over the life of a 1,000 Mwe plant. Of course the improvement in materials and techniques to permit achieving higher power densities and higher heat flux rates will have a great influence on reducing fuel cost.

The price of U_3O_8 could vary from $6 to $8 per pound up to 1980 without significantly affecting the cost of power. A change in the cost of U_3O_8 by $1 per pound would change the cost of power by about .07 mills per kilowatt-hour. A change of $4 per kilogram separative unit cost in enrichment service would also result in a change in the cost of power of about .07 mills per kilowatt-hour.

The price for the conversion of U_3O_8 to UF_6 was recently reduced by Allied Chemical from $1.25 to $1.04 per pound. With the market that is expected in the early 1970's and the building of competitive plants, one could expect that the price for conversion could be reduced considerably.

I am pleased to have had the opportunity to talk to you and I am sure that representatives from other segments of the nuclear industry will be glad to discuss the subject with you and I will try to answer any questions that you may have.

WASTE BYPRODUCT PRODUCTION *

R. E. Blanco
Oak Ridge National Laboratory

(Presented at the Nuclear Power Briefing for the Coal Industry, September 29-30, 1966, Oak Ridge, Tennessee.)

This afternoon I will summarize the status of the nuclear by-product disposal problem, or as it is more commonly called, the nuclear waste disposal problem and attempt to indicate the probable course of future developments. It has been said that a safe and economical solution to this problem must be found if nuclear power is to be successful. Actually, the importance of this problem is the result of the hazardous nature of these wastes rather than the cost of the operations since our studies predict that the cost of waste treatment will be only a small part of the total cost of nuclear power. In short, "We must ensure that these hazardous wastes are permanently isolated from the human environment by some practical method."

(1) Origin and magnitude of problem.
(2) Present treatment methods.
(3) Development of new treatment methods.

SLIDE 1. Origin of Wastes (66-680)

(a) Previous speaker described the recovery of unused thorium, plutonium, and uranium as products from the processing plant. The radioactive fission products are also produced as nuclear by-products.

(b) The radio-isotopes are true by-products if used by industry, but they are waste products if they serve no useful purpose.

(c) Three wastes types:

(a) Aqueous high level, intermediate level, and low level.
Stored in tanks or purified and discharged.

*Research sponsored by the U.S. Atomic Energy Commission under contract with the Union Carbide Corporation.

(b) Solid wastes are buried.

(c) Gaseous wastes are filtered to remove all radioactive particles and discharged up a stack. The air surrounding the stack meets all Federal requirements regarding radioactivity content.

(d) Radioisotopes can be recovered for use by industry as waste by-products. However, we do not predict that the cost of waste treatment will be decreased significantly by the sale of isotopes. We are not sure that the market will ever absorb all of the radioisotopes produced in the power industry.

(e) The other radioactive products serve no useful purpose and are called radioactive wastes.

(f) Liquid wastes are the greatest problem since they contain essentially all of the radioactive products.

SLIDE 2. Waste Management Program (65-11621)

(a) High Level

(1) High salt; 99.99% of fission products; relatively low volumes; now —> tanks; future —> solidify —> salt mine.

(b) Intermediate Level

(1) High salt; <0.01% fission products; relatively low volumes; now —> tanks or bury in concrete. Future —> bury in asphalt or inject as slurry of concrete into deep shale formations. We hope to minimize the volumes of this type of waste through improved processes.

(c) Low Level

(1) Low salt; just water with trace of radioactivity.

(2) Treatment and discharge. Present:

(a) Chemical flocculation.

(b) Ion exchange.

(c) Distillation.

(3) In large plants, chemical treatment cheaper than distillation:
$<1-6/1000 gal vs $15-100/1000 gal.

(d) Remaining discussion on high and intermediate level wastes only, since they constitute the major problem.

SLIDE 3. Approximate Volumes of Wastes and Fraction of Cost (66-640)

Not intended as a precise calculation; used only to show approximate distribution of costs.

(a) Note volume increase from High Level to Intermediate Level to Low Level.

(b) With mechanical decladding, small IL waste.
~110 gal/ton
Buried

(c) Relative importance of HLW is apparent. Recently much research and development work concentrated in this area.

SLIDE 4. Estimate of Waste Conditions in Year 2000 (66-1279)

(a) Estimate as of March 1966 based on AEC estimate in March 1965.

(b) Estimate is now being revised, but illustrates magnitude of the problem.

(c) Shows 31 million gallon of HLW in year 2000.

(d) More than 70 million gallons now in storage in the U.S. This waste contains much less radioactivity but the two volumes illustrate the magnitude of the problem.

(e) The new waste contains a much higher concentration of radioactivity.

(f) Total radioactivity in year 2000 equal to that from 500,000 tons of radium.

$$\frac{(\sim 5 \times 10^{11} \text{ total curies})}{(454) \quad (2000)} = \frac{5 \times 10^{11}}{1 \times 10^{6}} = 500{,}000$$

(g) Strontium 90 would be equivalent to 8,600 tons of radium.

(h) Total curies = greater than 5×10^{11} in year 2000.

~130,000 curies/gal after one year cooling

~7,000 curies/gal after 30 years cooling.

SLIDE 5. Present Methods for High Level and Intermediate Level (Photo 46189)

(a) All high level waste in the world is stored in tanks at the present time.

(b) Slide shows Savannah River storage tank.

(c) Contains: cooling coils

3 lines of containment (2 mild steel, one concrete)

(d) One million gallon tank costs about $1.5 million.

(e) Nuclear Fuel Services Co. tanks are ~700,000 gal.

SLIDE 6. Waste Storage Facility (Photo 46190)

(a) Facilities are complicated.

Future Methods

Some years ago under the sponsorship of the AEC, we conducted an extensive survey at ORNL to devise the safest possible treatment and storage method for high level wastes. The safest practical method that we could think of was to convert the waste to solids, preferably extremely insoluble solids, such as a glassy material, and then store it in a place where it would be isolated from water forever; for example, a salt mine where there has been no water for thousands of years. The insolubility of the solid waste would provide extra safety during the interim storage and shipment periods. The question was, "Was this system practical and economical?" We have pursued a development and economic evaluation program to answer the question.

SLIDE 7. Management of High Level Wastes (72614-83)

(a) Shows overall program.

(b) Economic evaluation of each step.

(c) Granite vaults 2 times more expensive and concrete vaults 5–7 times more expensive than salt.

(d) AEC also sponsored programs at ORNL, BNL, and Hanford Battelle's Northwest Laboratory to develop solidification methods.

(e) Work is being carried out at ORNL to determine the feasibility of storage in salt.

The remaining slides will summarize these studies.

SLIDE 8. Relative Volumes of Wastes from Purex Process (Photo 48506-C)

(a) Relative volumes.

(b) About factor 10 reduction from liquid to solids.

(c) What is the safety and economic advantages of conversion to solids?

SLIDE 9. Conversion of Waste to Glass (Photo 53673-C)

(a) Typifies the conversion step.

(b) Could also just evaporate to dryness and calcine to 500°C.

(c) These are the bases for the ORNL pot calcination and potglass processes.

(d) Glass has the advantages of high thermal conductivity and extreme insolubility.

SLIDE 10. Flowsheet for Converting Wastes to Solids (Photo 50885R)

SLIDE 11. ORNL Pots (Photo 54842)

(a) Stainless steel, 8 to 24 in.-diam x 8 ft high.

(b) Weld top shut - send to storage.

(c) Fill with glass product or calcine.

(d) One 12-in.-diam pot x 10-ft-long holds 6.08 ft^3 - 15 pots/year of glass would hold all high level waste from a 1000 Mw(e) reactor at 10,000 or 20,000 Mwd/ton.

SLIDE 12. ORNL Hot Pot from Furnace (Photo 59579-C)

SLIDE 13. BNL Continuous Process (CN3-1157-65 BNL Color Photo)

(a) Evaporator to remove liquid.

(b) Flows to a continuous platinum melter to form glass product.

(c) Glass product flows to pot receiver.

SLIDE 14. Hanford Spray Calciner (LR-Dwg. 53279)

(a) Spray dried.

(b) Melted to glass in continuous platinum melter.

(c) Flows to pot receiver.

These three new solidification processes will be tested with radioactive waste in a new pilot plant at Hanford's Battelle Northwest Laboratory. Radioactive tests are expected to start late in 1966.

SLIDE 15. Waste Carrier (Photo 80765)

(a) Experimental carrier is 4 ft diam and weighs 30 tons (35 ton limit by road).

(b) Required carrier for 30 year old fuel, 5 ft diam - holds 36 - 6-in. diam x 10 ft pots, weighs 50 tons - shipped by rail - air cooled by convection - 6-in. to 8-in. thick lead shielding.

SLIDE 16. Salt Mine Storage Facility (63-239R or Color slide 61622)

(a) Experimental unit; old mine at Lyons, Kansas. Leased by AEC.

(b) Easily and cheaply mined.

(c) Many old mines available; 1000 feet down.

(d) Salt beds widely distributed.

(e) Represents ultimate disposal with minimum or no future long term surveillance.

(f) No water; automatic sealing by salt plastic flow.

SLIDE 17. Carrier in Salt Mine (Photo 80977)

SLIDE 18. Experimental Pots in Salt (Photo 80997)

SLIDE 19. Salt Corridor (Photo 81000)

SLIDE 20. Waste Management Data for Conversion to Solids (66-1280)

(a) 34,000 ft^3/year in year 2000.

(b) 310,000 ft^2 total in year 2000. ≈ 2.3 million gal vs 31 million gal predicted if it remained as liquid.

(c) Need 3,420 ft of 48-ft-wide canals.

(d) Need 2.1 acres in year 2000 but have committed 1,185 acres of salt.

SLIDE 21. Costs for Storage (65-11624)

(a) Uranium at 10,000
Thorium at 20,000 Mwd/ton.

(b) New tank each 50 years.

(c) Interest rate 4%: present worth financing.

(d) Within limits of these estimates, costs are the same. Therefore, we feel that we are justified in recommending fixation in glass or calcination and storage in salt. This is the safest system that we can conceive of.

(e) Actually, total predicted cost is less than 1% of total cost of 3.5 mill power.

(f) Cost appears to be small but the importance of proving a satisfactory waste disposal method is very great, since, as I said at the beginning, a successful solution to the radioactive waste disposal problem is required if nuclear power is to be successful.

IN SUMMARY

(a) Present treatment methods for wastes, based on tank storage, are adequate, safe, and economical for an interim period.

(b) Improved treatment methods are now under development. As these programs culminate in the next few years we expect to demonstrate significant improvements in safety and economy. At that time, private industry will be able to choose the ultimate disposal system for their use with some certainty.

URANIUM AND COAL - PARTNERS OR RIVALS?*

Alvin M. Weinberg

The story is told of the hungry lion who was eagerly anticipating a meal of an early Christian martyr. When the Christian was thrown into the arena with the lion, he whispered something into the lion's ear whereupon the lion became deathly pale, trembled all over, and slunk back to his cage. After the Christian was set free he was asked: "What did you say to the lion?" and the answer was: "I told the lion he would be called upon to make an after-dinner speech."

I sympathize on this occasion with the lion. For I am expected, I suppose, to stand before you distinguished representatives of our country's coal industry, who have listened to a day's discussion of just how nuclear energy will put coal out of business, and persuade you that really uranium is coal's best friend. This I cannot do. So to speak, if uranium is coal's best friend, coal doesn't have to look for an enemy. So you will excuse me if I confess that this is an after-dinner speech which at first caused me plenty of indigestion.

Yet on thinking about the matter, I began to relish the job after I decided to speak this evening not as an official spokesman of the Atomic Energy Commission, (which I am not), nor even as the Director of the Oak Ridge National Laboratory, but simply as a former basic scientist who for the past 25 years has been fascinated by the problem of energy. Thus I

---

*For presentation before the National Coal Association Meeting in Oak Ridge, September 29, 1966.

shall try to look upon the relation between uranium and coal not from the viewpoint of a proponent of one source of energy, but rather more symmetrically, from the viewpoint of a person who believes that cheap energy is the world's most important resource. With the world's population increasing so rapidly, we shall stave off Malthus only if we can get more and ever more energy. It is my belief that every source of energy will be used in this energy-exploding economy; that each source will eventually find those spheres of use which capitalize on its strengths and minimize its weaknesses; and that the competition between the various sources of energy will tend to keep everyone honest, much to the benefit of the society that must use energy at an increasing rate. I shall therefore try to examine the strengths and the weaknesses of both sources of energy, and to suggest what seem to me to be the major technical problems that each must overcome before it can assume its ultimate and proper niche.

The Strengths and Weaknesses of Nuclear Energy

I begin with nuclear energy: what are its strengths and its weaknesses? Its strengths have been fully expounded today: 1. In large sizes, nuclear electricity appears to be extremely cheap. 2. Because nuclear fuel is compact, the price of nuclear electricity does not depend upon the location of the plant. 3. If breeders are successful, we shall have available an essentially inexhaustible source of energy in the residual uranium and thorium in the earth's crust. 4. Nuclear power plants can be built so as to be almost pollution-free. 5. Finally, nuclear energy is a child of aggressive large-scale research, much of it sponsored by the government, and it continues to profit by the research activities of a vast technical

establishment. Its weaknesses perhaps have not been expounded as fully by the speakers though, judging from the questions put by the NCA, nuclear energy does have weaknesses. I would list them as follows: 1. Nuclear energy is really cheap only in very large size - say 400 MwE and above. 2. Nuclear converters of the present generation burn only a small part of the uranium. Even if more cheap uranium is found, the cost of energy from burner reactors will eventually rise. 3. Though I believe nuclear power plants can be made arbitrarily safe, to do so requires elaborate "engineered" safeguards. How much these must cost to insure beyond any possible doubt against a nuclear catastrophe will always be a matter for argument. In any case, I can understand why so far people are reluctant to place large reactors very close to large cities. 4. Disposal of radioactive waste products from a large nuclear power plant is relatively complicated.

The nuclear community is aggressively capitalizing on its strengths and remedying its weaknesses. You have already heard how the nuclear world is mobilizing around the breeder problem. (Notice that I say breeder, not fast breeder, since I happen to belong to the minority that believes the thermal breeder based on thorium as a raw material is a better long-term bet than is the fast breeder based on uranium.) I might interject at this point my own opinion - that the cheap, safe breeder is one of our society's most important technological goals, and that we ought to be prepared to spend much more on it than we are now doing. In this I believe I agree with many spokesmen of the coal industry. And you have heard of the continuing search for ways to increase the safety of nuclear power plants and to dispose of radioactive residues safely and cheaply. My point

is that the nuclear community understands its strengths and its weaknesses and is mobilized sharply and decisively around them: if breeders are needed, let's get on with their development; if waste disposal is a problem, let's solve it, and so on. And of course in getting on with its job, the nuclear community has two advantages: first, the development of nuclear energy is high national policy and therefore enjoys heavy government support; and second, the industry is dominated by relatively few very large, technically-oriented companies that are accustomed to devoting a sizeable fraction of their income to scientific research and heavy technical development.

The Strengths and Weaknesses of Coal

Let me now list the strengths and weaknesses of coal, as I see them. Its strengths I list as follows: 1. Coal-fired power plants have operated successfully much longer than have nuclear plants. 2. Coal-fired plants, no matter in what size, need no engineered safeguards. 3. Coal's ashes, though troublesome, are far less dangerous than are fission products. 4. Coal-fired plants are cheaper than nuclear plants in the smaller sizes. 5. Coal, in addition to being a source of energy, is a valuable organic chemical and reducing agent: it can be used to reduce iron ore, and it can be converted into liquid fuels, or even into synthetic stockings. Its weaknesses I list as follows: 1. Coal contains noxious pollutants, like sulfur. 2. Coal costs about 20¢/MBtu compared to nuclear fuel, which may cost as little as 5¢/MBtu, and the cost of coal rises sharply with distance from the mine. This redounds strongly to coal's disadvantage in large size plants where the capital cost of the nuclear plant matches that of a coal plant. 3. The coal industry is relatively fragmented, and I suppose I

would say less scientifically oriented than is the heavy electrical equipment industry. 4. Coal, though supported by the Department of the Interior, hardly enjoys as much government support as does nuclear energy.

Having listed the strengths and weaknesses of coal, I shall now go through the list and try to see how the strengths can be capitalized on and the weaknesses eliminated. In so doing I shall try to take the point of view not of a proponent of either atomic energy or of coal, but that of a person concerned in the broadest way with energy in our society.

First, I remind you that the coal industry is in no imminent danger from nuclear fuel. During the past year, more coal was used in the United States than in any year since 1945. The approximately 8,000 Mw of new coal-fired power plants built last year are expected to run for a good 30 years; and with our demand for energy growing, I cannot see a diminishing absolute market for coal. The decision to go coal or go nuclear during the next decade, say, will continue to be a close thing, even in the large sizes where the economics favors nuclear power. In some cases residual doubts that utilities may have about nuclear systems will swing the balance toward coal. These matters will be discussed in more detail tomorrow at the panel on the role of various energy resources, and so I shall not dwell upon them.

The two main technical handicaps coal must overcome if it is to regain its unchallenged position as the fuel for large central stations is first, pollution by SO_2 and other waste products, and second, its relatively high cost of 20¢/MBtu. Let me first consider the second technical question. I ask, are there credible ways of reducing the fuel cycle cost in coal plants?

Two approaches are possible: first, to rationalize further the mining and hauling of coal; and second, to increase the thermal efficiency of coal-burning stations. I'm sure that this audience knows much more about mining and hauling of coal than do I - about the new automatic mining machines being developed by the Joy Manufacturing Company; or the unit-trains; or the coal slurry pipelines which at one time seemed to show so much promise. I can only urge that serious and thoughtful attention to these methods of reducing the fuel cycle cost be encouraged.

I would like to focus on the other, perhaps more promising, possibilities of reducing the fuel cycle cost - by increasing the thermal efficiency. One way which has received great public attention is by means of the magneto-hydrodynamic generator - MHD. Again I claim no expertise here, though my instinct somehow makes me rather skeptical: the very high temperatures required in a successful MHD generator pose serious materials questions whose solutions I cannot readily visualize.

Instead I should like to tell you of an interesting possibility that has grown out of the space-reactor work at the Oak Ridge National Laboratory. Mr. A. P. Fraas and his associates of ORNL have examined boiling potassium as a working fluid in a nuclear reactor. Potassium at atmospheric pressure boils at 1,400 degrees F. If it could be used as a topping cycle in a dual system much like the old mercury boiler that ran for so many years in Hartford, Connecticut, one could achieve a thermal efficiency of 55%. At this efficiency, for example, the fuel cost of the Cumberland City coal-fired plant which TVA rejected in favor of the Browns Ferry nuclear plant falls from 1.69 mills/kwh to about 1.20 mills/kwh. This is very close to the fuel cycle cost for the General Electric BWR, and distinctly lower than that of the Westinghouse PWR.

What would have to be done to bring the boiling potassium cycle into being? Obviously a great deal. But we have already operated a small turbine on boiling potassium for 2,500 hours, and there is no obvious reason why a much larger turbine could not be built. The turbine would have to be clad with Nb, as would the tubes of the potassium boiler; and this may turn out to be too expensive. However, I think the possibility deserves some attention, especially since a plant running at 55% thermal efficiency rejects only 55% as much heat to the environment as a plant of the same electrical output running at 40%. In my opinion, the path to 55% efficiency in large central power stations via the potassium turbine appears more credible than the path via magneto-hydrodynamics. If this is a reasonable path to follow, the knowledge created within the Atomic Energy Commission would be extremely useful in achieving the goal.

Let me return to the other technical problem faced by large coal-fired stations: pollution, especially by SO_2. This is a nasty problem which, as I understand it, is costly to eliminate. In this connection I might quote Congressman Chet Holifield, Chairman of the JCAE, who suggested that some of the expertise of the Atomic Energy Commission might be used to help figure out how to reduce the SO_2 effluent from burning coal.

> "If the power industry does not undertake to appraise the present pollution control problem in detail and police itself adequately, someone else - whether it be local, state or federal government - will impose further restrictions upon the industry. It would be far better for the power industry to set its own standards rather than to have restrictions imposed upon it from outside which may be unduly restrictive or unrealistic ...
>
> "The AEC's research and development facilities are second to none. Our objective should be to use them wherever they can be of value. For example, AEC has facilities to sample and measure contaminants in the atmosphere to exceedingly high degrees of accuracy. In addition, AEC has developed methods

of using radiation tracers to study processes such as those involved in the combustion of fossil fuels which will permit the analysis of the complete combustion and effluent process. In this way one could study the best ways of controlling and eliminating certain air pollutants.

"I certainly think the idea of utilizing specialized AEC capabilities for studying the problems of pollution control from fossil fuel plants is worth exploring. The importance of an adequate energy supply for the future goes far beyond a temporary competitive advantage of either nuclear over conventional fuel or vice verse. I am interested as a public servant in advancing the utilization and efficiency of all fuel resources. I believe it would be appropriate for officials of the electric utility industry to confer with responsible officers in the AEC and other executive branch agencies to discuss means of accomplishing this result."*

The Ultimate Place of Coal-Liquid Fuel

One admittedly long-range, though possibly very attractive, way of getting rid of SO_2 would be to liquefy coal, converting it to a crude oil essentially by adding hydrogen to the coal. In the process the sulfur is converted to the volatile H_2S which is eliminated from the final product.

This possibility of eliminating sulfur from coal by liquefaction leads to one of my main points - that in the battle for very large central station power, coal, even with the improvements I have envisioned, will ultimately lose to the most advanced breeder reactors. For example, the molten salt breeder, a pilot version of which you will visit tomorrow, should enjoy fuel cycle costs of about 0.3 mill/kwh. I estimate that such a system in 1,000 MwE size could, under TVA ground rules, produce energy at 1.5 mills/kvhE. Since in this reactor fission products are continuously removed, it has a certain built-in safety; and even if one fuels the reactor with thorium costing $40.00/lb., (there is enough in New Hampshire to meet the demands for many thousands of years), the cost of energy would still be below 2 mills, with TVA financing. In truth, I do not see any

*Nucleonics 24, 18 (July 1966).

possibility of large coal-fired plants meeting this competition which should be raising its head, seriously, in about 15 years.

Under the circumstances it seems to me common sense, and in the interest both of the nation and of the coal industry, for coal to move into a vast and different market: liquid fuel especially for vehicles and organic chemicals. However, since the market in organic chemicals is measured in millions of pounds/year, not millions of tons, I shall concern myself with the possibility of liquid fuels from coal.

The crisis that coal faces - if indeed one can describe as a crisis a situation in which coal still accounts for 24.5% of our energy - will not really take hold for 15 years or so. During that time we shall be mining our crude oil at an increasing rate. The current average price for domestic crude oil is $3.00/bbl., though the range goes from $2.00/bbl. to $3.40/bbl. for normal crude to $4.63/bbl. for high-grade Pennsylvania crude. Even though foreign crudes can be expected to come in at lower prices, I cannot imagine our country ever allowing itself to get in the position where we do not have an adequate domestic crude oil supply. Thus, we shall eventually have to get oil from solid materials - either from coal or from oil shales. When we shall have to do this on a large scale will depend on many factors and will vary from place to place: for example, in South Africa, which aims at self-sufficiency, oil (as well as many petrochemicals) is now produced on a huge scale from coal at the SASOL plant.

Where then do we stand in converting coal into oil - and is there any way in which nuclear energy can help? Basically, the problem in liquefying coal is to add hydrogen to the carbon contained in the coal - to

change C_2H, which is approximately what coal is, to CH, which is roughly the composition of liquid hydrocarbons. The hydrogen for this process can be obtained independently, say by electrolysis of water; or by steam-coal reforming with very high-temperature heat obtained from an outside source; or by steam-coal reforming with heat obtained by burning some of the coal with oxygen. These three processes are summarized in Fig. 1, prepared by C. E. Guthrie of the Oak Ridge National Laboratory. As you can see, the estimated minimum cost of $2.40/bbl. does not include losses, operating and maintenance costs, taxes, insurance, or profits. Nevertheless, one cannot escape the impression from the figures that liquid fuel from coal ought to become competitive in our country within a generation - roughly at the time when the requirement of coal for fueling central power stations diminishes.

What role can nuclear energy play in this great redeployment of coal? I see two possible roles, though I want to make clear that both of these are rather speculative at present. First, if the molten salt breeder, for example, can produce electrical energy at 1.5 mills/kwh, then we could electrolyze water with this cheap power to extract hydrogen at 20¢/MSCF; this is the source of the price used in the Guthrie Table, Case A. And secondly, if we can get high temperature by heating with electricity at 1.5 mills/kwh, rather than the 2.5 mills/kwh assumed in the figure, we could reduce Guthrie's $2.40/bbl. to perhaps $2.20/bbl. Or alternatively, if the high-temperature heat could be obtained from a reactor directly, this would be much more efficient than electric resistance heat, and could be used to advantage for the endothermic steam reforming step in Case B.

I would be doing you a disservice to pretend that I see a clear way for coal to take over the vast market for liquid fuel - either with or

without the help of uranium. But I am convinced that this is a most important direction to investigate thoroughly and seriously, and that the country's scientific resources ought to be deployed massively around this problem.

The Indivisibility of the Problem of Energy

This brings me to my last point. I listed as a weakness in coal's position its relative fragmentation, and its relatively unscientific tradition as compared with oil which is dominated by extremely large companies that are strongly influenced by science. It goes without saying that coal, in order to hasten the arrival of the time when liquefaction is economical, will have to devote more resources to research. Perhaps this will be done entirely within the coal industry - probably more likely through mergers between coal and oil companies, as illustrated by the recent merger of Continental Oil Company and Consolidation Coal Company.

Insofar as the large-scale conversion of coal to liquid hydrocarbons is a matter that touches the national interest, I believe the government should be involved, and involved heavily. To some extent this is already going on: the Bureau of Mines and the Office of Coal Research together have spent 10 to 12 million dollars per year on developing methods for liquefying coal. The AEC has pursued a very high-temperature reactor experiment, the UHTREX at Los Alamos aimed at providing heat for hydrogenation of coal. I would think it reasonable for government to take as seriously as the technology allows the problem of coal liquefaction in all its manifestations: generation of cheap hydrogen via cheap nuclear electricity, new process heat reactors, possibly using boiling potassium as a working fluid.

The rivalry between coal and uranium is good and in the best American tradition. It is good for coal to be put under the kind of economic pressure that forces it to improve mining methods, and come up with unit-trains. It is good for uranium to be asked sharp, no-holds-barred questions such as Mr. O'Brien and his staff at NCA are so good at asking.

But I think there is still something lacking. Nuclear energy has its government champion - the AEC and the JCAE; coal energy has its government champion - the Department of the Interior. I cannot fault either of these two vigorous and well-run agencies. Yet I would raise the question - should there not be some home in government for energy itself - not nuclear, or coal, or oil, or solar, or water - but all forms of energy which, after all, is the ultimate raw material?

That some such feeling must exist in Washington is suggested by the energy study that has been going on for several years in the Office of Science and Technology under the leadership of Ali Cambel, of Northwestern University, and that we are all awaiting. This study will look at the entire energy picture. I should think that the broad responsibility for energy suggested by the outlook of such studies might well become the job of some yet-to-be organized agency.

I realize that in suggesting that we alter existing government structures, I am treading on the most treacherous political ice. Yet I said at the beginning of my talk that I was speaking not as a representative of AEC nor for that matter of the Department of the Interior for whom ORNL also does work. I speak simply as a person deeply convinced of the increasing role of energy in our society. From this point of view, I believe it to be an important order of business of our government to reexamine its alignment and structure for dealing with the broad problem of

energy. Out of such a reexamination I hope will come a more rational way of coping with our society's ever-growing, and even insatiable, demands for energy, and that the full potentials of both uranium and coal will be exploited for the benefit of all.

EVALUATING THE COST OF NUCLEAR VERSUS FOSSIL-FUELED POWER PLANTS

Presentation By G. O. Wessenauer, Manager of Power,
Tennessee Valley Authority
At The
Nuclear Power Briefing For The Coal Industry
U. S. Atomic Energy Commission
Oak Ridge, Tennessee
September 30, 1966

Description of the TVA System

TVA supplies the power requirements of the region it serves from the output of 47 hydroelectric plants and 11 steam plants. These generating plants are connected with each other and with the loads they serve by 14,000 miles of high voltage transmission line, including 400 miles of new extra-high-voltage (500-kv) lines. The TVA system has strong interconnections with the major electric systems in adjacent areas. (See Figure 1.)

Load Growth

Rapid growth is a significant characteristic of loads in the TVA region.

Starting in 1933 with 250,000 kilowatts of capacity in the Wilson Hydro Plant and the Wilson Steam Plant, TVA has responded to the region's thirst for power until, today, system capacity exceeds 18 million kilowatts. Of this, about 4 million is hydro and 14 million is steam. (See Figure 2.)

A coal burning unit with 1,150,000 kilowatts is now under construction and designs are under way for two nuclear units of 1,152,000 kilowatts each.

By 1971, when the second nuclear unit is scheduled for service, system capacity is expected to exceed 21 million kilowatts.

TVA's engineers already are anticipating the day when the region's power requirements will reach 50 million kilowatts, and the facilities TVA is building are designed with a 50-million-kilowatt-system in mind.

Load growth is one of the most important factors any electric system considers in deciding the kinds of generating facilities it should install. A combination of large total loads and rapid load growth permits the economies of scale that come from large individual generating units, the concentration in one plant of several such units, and extra-high-voltage transmission.

Large scale operations are especially important in the evaluation of nuclear power plants because the investment cost per kilowatt of capacity and the operating cost per kilowatt-hour decline much more rapidly as size increases for nuclear plants than for plants that burn a fossil fuel.

Economies of scale are so very important that there is a trend toward the pooling of interests among otherwise independent systems, in which two or more systems share the use of facilities that might be too large for the systems individually.

System Economics

The generating capacity available to an electric system must always be greater than its anticipated loads. Reserve generating capacity

is needed so units may be removed from service for scheduled maintenance, and to meet unexpected outages and unexpected load growth.

It may be helpful to our discussion to note something of the way an electric system meets its loads.

Figure 3 shows typical hourly load curves for a week in winter, which is the season of TVA's peak loads, and for a week in spring, which is an off-peak season. On the TVA system, as on all systems, loads vary from hour to hour, from day to day, and from season to season, so that generating units are operated for varying proportions of the time. Some capacity must be operated at all times to meet the minimum loads but some is operated intermittently and for relatively short periods to assist in meeting the peak loads.

Figure 4 is an Annual Load Duration Curve. It is derived by arranging each of the hourly loads in a year from left to right in descending order. The chart has been simplified by drawing a straight line to depict the load duration, when in reality it is a curve. Shown on the chart is the generating capacity used to carry the loads.

The chart shows that about 8 million kilowatts of generating capacity, mostly steam but some hydro, operate 100 percent of the time; roughly 11 million kilowatts, or more, operate about 50 percent of the time; and 14 million kilowatts, or more, operate for shorter periods to meet peak loads.

The load under the duration curve is supplied by the hydro and thermal plants in such a way as to minimize system operating costs. The hydro units, because of their quick starting and stopping ability, are operated the maximum extent possible to utilize the available water for supplying the peak or variable portion of the load. The thermal units with the lowest incremental operating costs are operated the highest percentage of the time and, therefore, are shown supplying the base portion of the load; those with the higher incremental costs operate fewer hours and supply intermediate loads. The highest-cost thermal units operate only during hours of peak load or during emergencies.

The amount of coal burned depends on two elements in this chart: first, the proportion of coal-fired plants that make up the system capacity; and, second, the percentage of time during which the coal-fired plants are operated.

This simplified chart does not show the use of economy and emergency interchange with adjacent electric systems, but TVA does exchange power with other systems, and these exchanges offer significant savings.

TVA's purpose, and the purpose of the neighboring systems with which it interchanges power, is to operate at all times the most economical plants on all systems. In addition to the day-to-day and week-to-week economy exchanges, TVA exchanges large amounts of power seasonally with systems to the south and west.

TVA delivers large blocks of power to them during the summer months which is returned by them to TVA during the winter months. In effect, TVA generates on its own system all of the annual energy required by its annual load.

TVA's large transmission network permits wide flexibility in the choice of generating units to supply the loads. This interchangeability of generation permits use of the most economical power sources to minimize system costs.

Alternatives to Meet Load Growth

Figure 5 is the same load duration curve, except that one year's growth has been added. To show how TVA might use hydro and steam capacity to meet load growth, the portion represented by that growth has been sandwiched between the hydro and steam generation.

What are the alternatives open to TVA in meeting that growth?

Enough additional capacity--in kilowatts--including appropriate reserves, must be added to meet this added peak load as shown along the left edge of the chart; and enough electric energy during the year--in kilowatt-hours--to meet the total energy represented by the load growth band.

There are several ways to provide this capacity. One is to install plants that operate only during peak periods, supplying the bulk of the added energy requirements from existing plants. (See Figure 6) This method can be advantageous if the capacity from the peaking plant has a low capital cost even though it might have a

relatively high operating cost. Peaking capacity can be in the form of hydroelectric projects and various types of fossil-fired generating plants. Some of these plants can be erected at a cost which is only two-thirds to three-fourths the cost of a base-load plant of equal capacity. Since a peaking plant is designed to operate only a small part of the time, the added investment for equipment to gain the extra ounce of efficiency so valuable in a base-load plant is saved. Thus, the incentive is to minimize use of the peaking plant and to increase the use of existing thermal plants.

One type of peaking plant is the pump-storage hydro plant, in which water is pumped uphill to a storage reservoir during off-peak hours for use in driving generators during peak hours. TVA has been considering for some time such a plant that could produce at least a million kilowatts of capacity on peak, (roughly one year's load growth), and modest amounts of energy. To supply the energy portion of the load growth, TVA would have to operate existing coal-fired steam plants a greater portion of the time. Because even the energy attributed on this chart to the pump-storage peaking plant originates in a coal-fired plant, a pump-storage hydro plant would increase coal purchases enough to meet the entire load growth.

Another way to meet load growth is to construct a base-load thermal plant, either coal-fired or nuclear. A new, base-load thermal plant would produce kilowatt-hours at a lower incremental cost than any of the older capacity shown on the chart as operating

less than 100 percent of the time. For that reason, it would operate a high percentage of time, displacing in part generation at the older higher-cost plants so that the amount of energy it produces would be greater than needed to meet load growth alone. Figure 7 shows the total energy that would be produced at a new base-load plant, and the extent to which this generation would replace energy produced at older and higher-cost, coal-fired plants.

The effect of a new thermal, base-load plant on coal purchases will depend, of course, upon whether it is coal-fired or nuclear. If it is coal-fired, system coal burn will increase considerably. To the extent that the new plant burns coal to meet that portion of the load that previously was served by older coal-fired plants, the coal burn may be slightly less due to the better heat rate of the new plant; but the operation of the plant to meet load growth will result in a substantial increase in coal burn. However, if the new, base-load plant is nuclear, coal burn will not only fail to grow as loads grow, but there will be a net reduction in system coal burn.

The decision to build a peaking plant or a base-load plant depends upon which combination leads to the lowest overall costs projected over the life of the new plant. That is, the capital cost of the peaking plant added to the present worth of the operating costs of it and the older coal-fired plants over the life of the peaking plant must be compared to the capital cost of the base-load plant

plus the present worth of its operating costs less the savings in operating costs of the older coal-fired plants.

I would like to emphasize that the factors governing the decision to construct a new plant are different from the factors governing the decision to run that same plant after it is in service. Before a plant is built it must show a lower total cost--including the investment in the plant and transmission, and operating and maintenance expense. But once it is built the plant's relative incremental operating and maintenance expense, which is 85 percent fuel, determines the extent to which the plant is operated.

Nuclear Versus Coal-Fired, Base-Load Unit

Nuclear power plants and coal-fired plants both generate electricity by producing steam to drive turbogenerators. The essential difference between the two is that one uses nuclear fission in supplying the heat to produce the steam and the other burns coal.

A question that continues to be raised is "At what price levels will coal be competitive with nuclear fuel?" This question was reemphasized after General Electric and Westinghouse made their nuclear proposals to TVA, so a review of the evaluation which TVA made may be useful.

Because TVA's evaluation report has been in wide demand, and most of you may have copies, the review will be brief.

TVA's evaluation compares the cost of a coal-fired plant assumed to be located near Cumberland City, Tennessee, which is about 50

miles northwest of Nashville on the Cumberland River, with the cost of a nuclear plant located at Browns Ferry near Decatur, Alabama.

In choosing the most economical location of a coal-fired plant, two important factors are the delivered cost of coal, including the cost of transporting it from the mine to the plant, and the cost of transmitting the power from the plant to the load centers in which the added power supply is needed. A third factor occurs when, as in the TVA area, the lowest cost coal seldom occurs in an area where there is adequate condensing water, so that a mine-mouth plant may require an investment in cooling towers, as at TVA's Paradise Steam Plant. There is adequate condenser cooling water at Cumberland City, and no cooling towers would be needed.

Thus, in locating a coal-fired plant, we seek the lowest combination of (1) the cost of coal, including its transportation; (2) the cost of transmitting power; and (3) the plant investment, including, if needed, the cost of cooling facilities. Because of the importance of the cost of transporting coal, it is desirable to choose a site that can be served by barge, rail, and truck.

In picking a site for a nuclear plant, because the cost of transporting nuclear fuel is relatively small, the distance from the fuel supplier to the plant is a less significant consideration than for coal. The fuel can be chosen through competitive bids from sources that may be widely dispersed geographically. Among the

important variables in siting a nuclear plant are the cost of transmission and the cost of any cooling facilities. Because adequate condensing water is available in widely dispersed sites in the TVA area, a nuclear power plant can be located very close to the loads it will supply, thereby holding the cost of transmission facilities to a minimum.

The Cumberland City site offered the best combination of costs for the coal-fired plant to serve the load growth TVA needed to supply. And the Decatur area offered the best site for the nuclear plant. The Browns Ferry site was nearer to where a new source of power was needed in 1970 than the Cumberland City site.

Figure 8 summarizes the main items of the comparisons of the three alternatives. In choosing among alternatives, it is sufficient to measure the cost of energy delivered to the transmission system from the alternatives. Other system costs, involving capacity margins, transmission, marketing, and administrative costs, which are common to each alternative, need not be included. Note that in the comparisons there were some differences in the generating capacities of the three plants. TVA wanted bids on units of about one million kilowatts, but encouraged each manufacturer to choose the most economical unit he could offer in this size range.

The heat rates vary among the three plants from 8,946 Btu/kwh for the coal-fired plant to 10,558 for the boiling water reactor, which is the one TVA chose to build. The heat rate of the coal-fired plant is lower than the heat rate of the nuclear plant because it uses higher steam pressures and temperatures and pro[illegible]

for reheating the steam. Fuel costs ranged from a low of 11.86 cents a million Btu for the B&W plant to a high of 18.90 cents a million Btu for the coal-fired plant.

The fuel costs shown here have been levelized for the first twelve years of operation, the period over which the cost of the nuclear fuel was guaranteed to TVA. The levelized fuel cost is the uniform annual cost which has the same present value as the variable costs of the proposals.

The estimated capital cost per kilowatt of capacity for the nuclear plant TVA chose to build is about the same as the coal-fired plant--$116 compared with $117. One reason the costs were so close is the large size of the units. It has taken years of technological development and cost cutting to reduce the cost of large, coal-fired plants and it is significant that the cost of nuclear plants, which are practically in their infancy and for which substantial future improvements in design and economies in erection seem highly likely, already are no higher in cost than coal-fired plants.

Approximately two-thirds of the estimated total direct cost of the nuclear plant is for equipment being supplied by the manufacturer under a firm contract price that is not subject to escalation, whereas only about 14 percent of the estimated total direct cost of the coal-fired plant is based on firm bids. This lends assurance to the adequacy of the estimates and is very important in times such as these, when costs are rising so steadily.

The lower investment in transmission facilities required by the nuclear power plant reflects the point already mentioned, that the Browns Ferry site is located somewhat nearer the area on our system where additional power supply is needed in 1970 than is the Cumberland City site.

Fixed charges for interest and depreciation are much the same for all three plants. In all cases, interest at 4½ percent and an economic life of 35 years were used.

The cost of fuel to produce a kilowatt-hour of electric energy is the product of the plant heat rate and the price which must be paid for the fuel, including interest cost on fuel inventory. In TVA's evaluation, the advantage which the coal-fired plant enjoyed in its heat rate was more than offset by the relatively higher cost of the coal, with the result that the BWR nuclear plant is estimated to produce a kilowatt-hour of electric energy for 1.25 mills for fuel compared with 1.69 mills for the coal-fired plant. These costs include an allowance for interest on the fuel inventory, which, for the nuclear power plant, makes up about 10 percent of the total fuel cost and which, for the coal-fired plant, makes up about 1 percent.

Not only are fuel costs lower for the nuclear plant, they have the added advantage to TVA of being more certain than the coal costs of the coal-fired plant. The coal bids provided for escalation of price beginning with the date of the bid and are based partly on the U. S. Bureau of Labor Statistics Wholesale Price Index and

partly on a labor and material index; escalation on the nuclear fuel for the BWR plant will not start until 1975, about nine years from now; and even then it is based wholly on the Wholesale Price Index which in the past has increased much less than indexes directly related to labor and material costs.

Operating and maintenance costs of the nuclear plant include special costs that do not arise with a coal-fired plant, including the disposal of all radioactive materials. But these special costs are more than offset by the much higher operation and maintenance costs of the coal-handling facilities in a coal-fired plant. A staff of about 150 people is estimated for the nuclear power plant compared with about 250 for the coal-fired plant; most of the difference is for the operation and maintenance of coal-handling equipment.

In summary, the total cost of energy from the boiling water reactor plant delivered to the transmission system is estimated to be 2.39 mills a kilowatt-hour compared with 2.90 mills for energy from the lowest cost coal-fired plant that would meet system needs. The savings are estimated to be equivalent to $8 million a year during the first 12 years of operation, with the possibility of higher annual savings after this initial operating period.

Conclusion

In closing, it should be emphasized that TVA has no special preference between coal-fired and nuclear plants for producing electric power. TVA's interest is to use the power supply facilities which result in

the lowest cost so it may continue to fulfill its responsibility to serve electric consumers at the lowest possible rates.

True, TVA has a particular responsibility for multipurpose water control projects which provide many benefits, including flood control, navigation, municipal and industrial water supply, recreation, and hydroelectric power. A combination of thermal and hydro power is highly advantageous for a regional power supply. TVA has owned coal-fired generating capacity since the day it started operations. When opportunities for further economical hydro power development became minimal, it added to its coal-fired capacity to meet load growth.

Today, nuclear power offers an alternative to coal-fired thermal plants and portends to be an even stronger competitor for meeting future power needs. We expect that coal will leave no economic stone unturned in meeting that challenge. TVA will continue as in the past to evaluate and to compare before deciding on future plants.

With those of you who produce coal and those who transport it, TVA has a mutual interest. It is to keep the delivered cost of coal competitive.

TVA expects to continue to cooperate with the coal industry, with railroads, and with barge and truck lines to work toward this mutual interest so TVA may best fulfill its responsibility to the electric consumer of this region.

DEFENDANT'S EXHIBIT 136

Caution: Commonwealth Edison is hazardous to your health

Commonwealth Edison Company is the biggest coal user in the city, currently consuming over 3,900,000 tons of coal a year. This results in an annual discharge of over 234,000 tons of deadly sulphur dioxide into Chicago's air.

Edison has opposed the enforcement of the 1969 Chicago ordinance requiring reduction in the level of sulphur in fuels used in Chicago.

Commonwealth Edison's official position is callously indifferent to the public interest:

Edison's Public Statement
Edison intends to comply with the ordinance deadlines which existed prior to the extension.

Fact
Wrong. Even before the City Council extended the compliance deadline, Edison had sought an administrative exemption from the low-sulphur limitation. Under Edison's own proposals, Edison will be consuming 2.1 million tons of high-sulphur coal in 1969 with a resultant discharge of 147,000 tons of sulphur dioxide into Chicago's atmosphere.

Edison's Public Statement
Low-sulphur coal is not available in Illinois.

Fact
In 1968 Peabody Coal Company agreed to mine low-sulphur coal reserves near Troy, Illinois. Peabody has since abandoned its proposal. Yet Peabody continues to be a major supplier of Edison's coal needs. Why didn't Edison use its economic leverage against Peabody to demand low-sulphur coal from Peabody? New York's Consolidated Edison demanded and is now receiving coal with a less than 1% sulphur content from its suppliers. In addition, 3 out of 4 Edison generating stations in Chicago have natural gas capacity. Why doesn't Edison ask the gas utilities to supply gas power on a full-time basis?

Edison's Public Statement
Edison is doing everything it can to combat air pollution.

Fact
Wrong. Edison's generating plants pour thousands of tons of particulate matter into Chicago's atmosphere every year. Edison's present air pollution control devices (precipitators) are highly inefficient by current technological standards. If Edison persists in using high sulphur coal it could at least provide more efficient precipitators.

We, The Hyde Park-Kenwood Community Conference, on behalf of the citizens of Chicago want to know what Edison will do to meet next year's compliance deadline. Will next year bring a new extension demand or will Edison comply with the sulphur limitations?

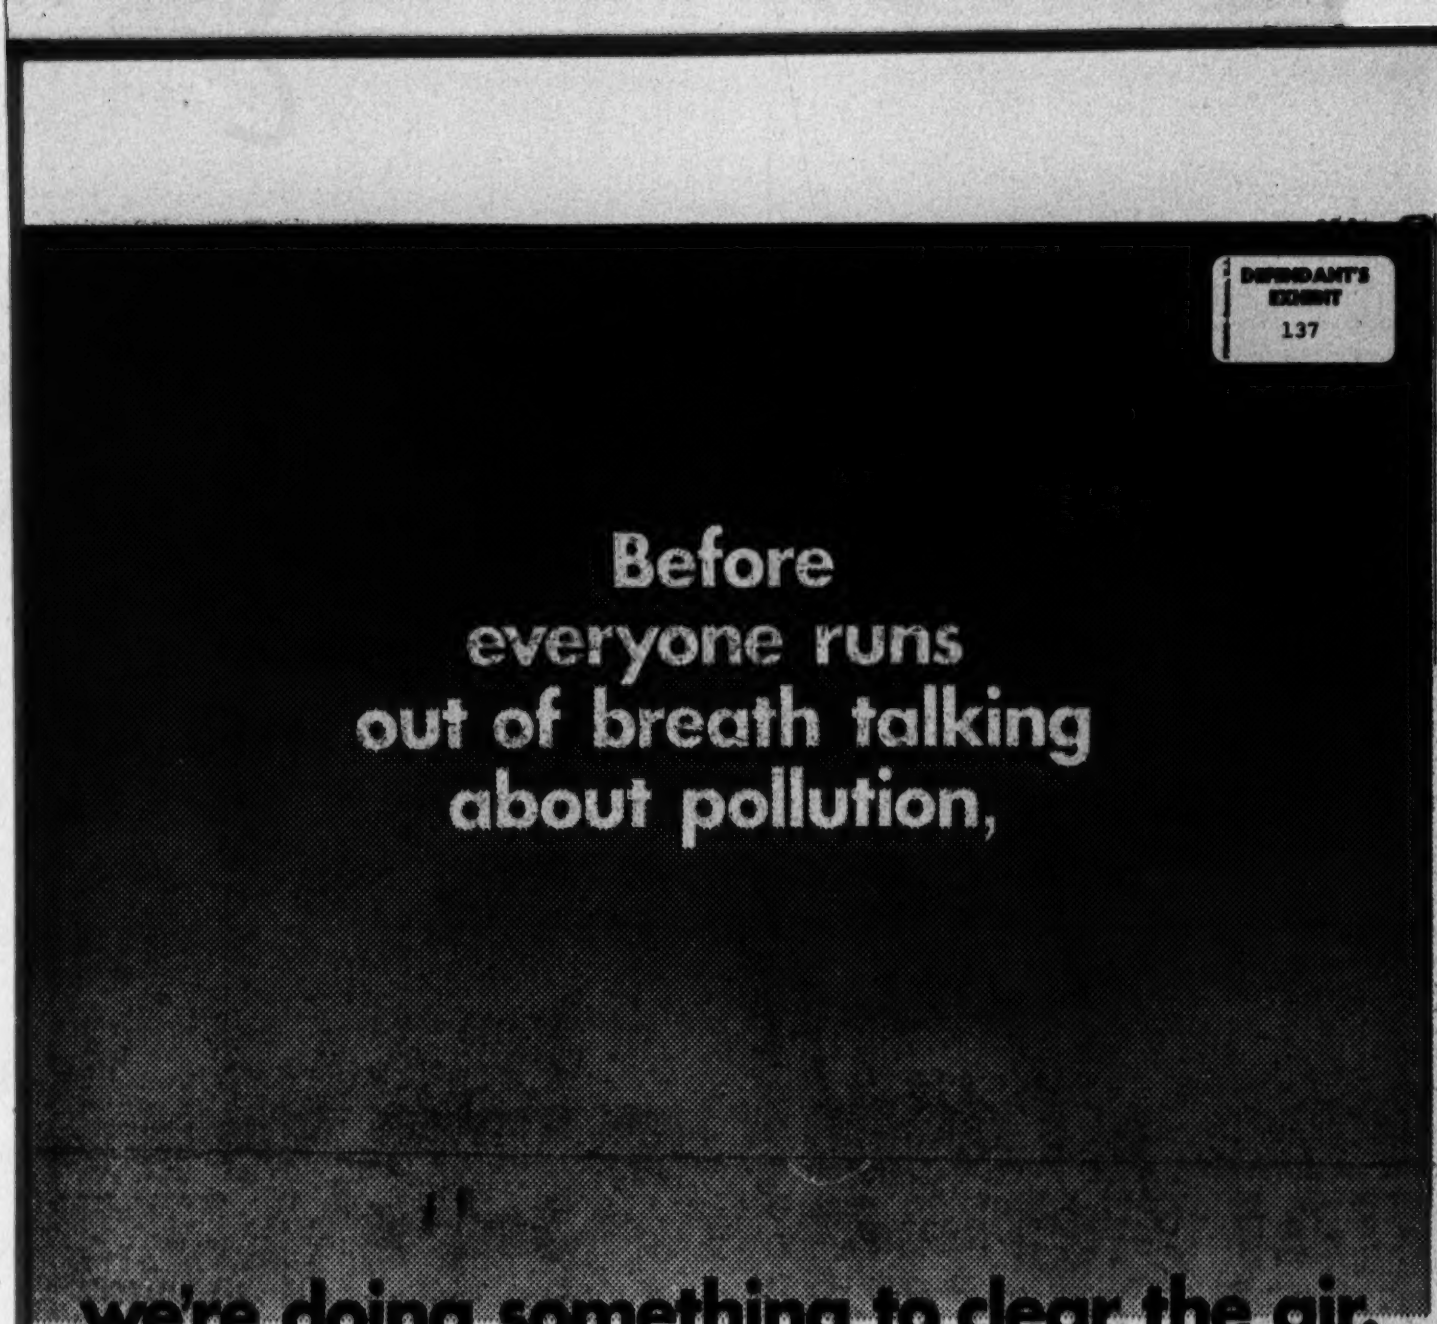
We await Edison's reply.

The Hyde Park-Kenwood Community Conference

5200 South Harper, Chicago, Illinois 60637
KAI NEBEL, Chairman

DEFENDANT'S EXHIBIT 137

Before everyone runs out of breath talking about pollution,



we're doing something to clear the air.

Gas is the cleanest energy there is anywhere. It's cleaner to produce and cleaner to use than coal, oil or gasoline.

IN CHICAGO

Most Chicago residents use natural gas for heating, cooking, clothes drying and water heating. And it's a plain fact that the more Chicago uses gas for these purposes, the cleaner our air will be.

Commonwealth Edison Company is one of our customers. Our sales to Edison during the past year totaled about 241 million therms of gas, more than triple the quantity they bought from us four years ago. The gas we sold them replaced 1.19 million tons of coal for making electricity, and eliminated 83,100 tons of sulphur dioxide from the air.

During the last six years, our sales to Edison totaled more than 846 million therms. It replaced 4.1 million tons of coal and eliminated 290,500 tons of sulphur dioxide from the air we breathe.

Gas-fired incinerators and fume incinerators are now being used by commercial, industrial and residential customers to dispose of waste materials and eliminate obnoxious odors. More of this equipment is being installed every year.

LOOK AT THE RECORD

In Chicago alone since January 1, 1964, gas has replaced coal and oil-burning equipment for commercial, industrial and residential purposes at a steadily increasing rate. Those replacements are now eliminating about 200,000 tons of sulphur dioxide pollution from the air each year.

GAS SUPPLY

We have repeatedly pointed out, that because of physical and economic limitations, natural gas alone cannot solve the total problem. Nevertheless, Peoples Gas is doing everything in its power to decrease air pollution by increasing the use and supply of natural gas.

During the past six years, Peoples Gas has spent 512 million dollars to build additional pipelines and increase its underground storage capacity. On January 1, 1964 our system's daily delivery capacity was 2.8 billion cubic feet. Now it is 4.9 billion cubic feet—the equivalent of 233,000 tons of coal or 32 million gallons of oil per day.

PLANS FOR 1970

In the coming year, we plan to spend 51 million dollars more to expand our supply and storage system. That will increase the supply of natural gas by an additional 528 million cubic feet per day—for even more clean air.

Peoples Gas

UNION ELECTRIC COMPANY

Strong Industrial and Civic Growth Continues

• • •

cost of over $14 million. It will join a similar line between Minneapolis and Hills which is being completed this Spring by Iowa and Minnesota companies. This St. Louis-Minneapolis line will permit the interchange of as much as a half million kilowatts of power between the several utilities involved.

Construction also was started during the year on the Company's portion of a 345,000 volt St. Louis-Kansas City transmission line, which is expected to be in operation in the Spring of 1968. It will strengthen the power supply for much of the State of Missouri, as well as the States immediately west of us.

Transmission ties with our Ill-Mo Pool partners (Illinois Power and Central Illinois Public Service) are being strengthened by 345,000 volt interconnections and the other members of the Ill-Mo Pool are coordinating their extra-high-voltage programs with companies to the east and north to facilitate the transmission of large blocks of power in and out of the Pool. Improved system reliability and economy will result through this coordinated program.

Also, 345,000 volt lines will provide the major transmission between the new Sioux and Labadie Plants and bulk transmission substations. When these lines are completed, the St. Louis area will be almost encircled by extra-high-voltage lines to provide for the most economical delivery of large amounts of power.

New Offices

The Company's general office building at 315 North Twelfth Boulevard in St. Louis was sold in June 1966. Executive offices will be moved within the next year to the new Gateway Tower Building on the St. Louis riverfront. Other departments were moved early this year into the Company's new general offices at 1901 Gratiot Street in St. Louis which are designed for more efficient operations.

The Emphasis on Research and Improved Efficiency

Union Electric has participated in nuclear power research as long ago as 1951 when we joined with Monsanto Company in feasibility studies of a multi-purpose reactor plant. In 1953, we joined with a number of other utilities to form the Nuclear Power Group and participated in the research and development culminating in construction of the initial 200,000 kilowatt Dresden Nuclear Power unit on the Commonwealth Edison system.

We have continued in close touch with the rapid technological developments in nuclear power during recent years as part of our long range studies of the economics of producing electricity from this form of energy. An important asset to our Company is its close proximity to the vast reserves of low-cost coal in southern Illinois. However, it is quite possible that a nuclear plant on the Union Electric system will be economically attractive by the mid-1970's.

Throughout our organization there is continuing emphasis on research and work improvements. Our activities range from better use of hand tools to highly sophisticated methods of calculating and dispatching

DX 147

Union Electric Company - 1967 Annual Report

* * *

A 345,000 volt interconnection with MAIN was completed in mid-1967. This high voltage tie links us directly with MAIN through our Ill-Mo Pool partners to the east. The MAIN network covers 10 states, embracing much of the Midwest and extending as far east as Virginia.

As part of our membership in MAPP, we also completed our portion of a 345,000 volt line extending from St. Louis to the Minneapolis-St. Paul area. The 250-mile Union Electric portion was constructed at a cost of $14 million, and the interconnection permits the exchange of up to 500,000 kilowatts of power. MAPP includes utilities in the states immediately west of MAIN and extends north into Canada.

Construction continued on a 345,000 volt St. Louis-Kansas City line which is scheduled for completion in 1968. This will strengthen the power supply for much of Missouri, as well as the states immediately west of us.

Union Electric's Beautification Program

The Company is engaged in a long-range beautification program to improve the appearance of its transmission and distribution lines, substations and transformers.

Residential underground distribution is desirable and practical in new subdivisions where the additional cost can be justified. On a system-wide basis, however, the cost of placing all lines underground would be prohibitive. It is estimated that the average residential customer's bill would have to be more than three times the present amount in order to finance the removal of all overhead lines and their relocation underground.

Our program includes the use of low profile substation equipment where possible, gray colored poles and transformers to minimize contrast, the elimination of cross arms, better looking hardware, and so on. We also make extensive use of camouflage with trees and landscaping.

We believe there has been a considerable improvement in the appearance of our overhead facilities, and the effort is a continuing one.

Nuclear Power

As reported to stockholders in the past, the Company's proximity to vast reserves of low cost coal ideally suited for steam plant generation has heretofore given coal-fired plants an economic advantage on our system. However, we keep well informed of the rapid technological developments in nuclear power, and a nuclear plant on the Union Electric System may be economically attractive within the coming decade. In 1967 we retained the NUS Corporation of Washington, D. C., an engineering consulting organization, to assist us in evaluating nuclear plant sites in the Company's service area.

* * *

The challenge/expansion

north, east, and west through extra-high-voltage lines.

Union Electric is a member of two of the nation's largest power planning groups—MAIN (Mid-America Interpool Network), operating in the Midwest and extending east into Virginia, and MAPP (Mid-Continent Area Power Planners), operating in the states west of MAIN and extending north into Canada.

The plans of both groups are being implemented very effectively. For example, when the huge MAPP system was formed five years ago, its member utilities planned 5,400 miles of EHV lines to be completed by 1980. As of year end 1968, more than 2,500 miles were completed and the network is now expected to be nearly complete by 1972. MAPP members already are planning to build another 5,000 miles by 1980 to create an over-all, interconnected extra-high-voltage grid of 10,400 miles.

Research and Development

Research and development programs at Union Electric— the constant probing for new devices, new methods—are basic to providing reliable electric service to our customers at lower cost and to improving the Company's contributions to the community in environmental control.

A highlight of the year was the $1 million installation at the Company's Meramec Plant of the nation's first full-scale system for the removal of sulfur dioxide from the stack emission of a coal-fired steam generator—a research effort that will produce significant progress in air pollution abatement technology. At year end, after a three-month "break-in" period, the installation was removed from service for design modifications. It is now back in service with improved performance. This system, which was designed and installed by Combustion Engineering, Inc. was named one of the "engineering achievements of 1968" by the National Society of Professional Engineers.

In a related project, Union Electric engineers have been working to improve sulfur dioxide air monitoring equipment at eight stations which the Company has placed in service around the Sioux and Labadie plants. Data from these stations, along with data from stations operated by governmental authorities, will form an air quality measuring network for the St. Louis area.

As another aspect of environmental control, the Company is engaged in a long-range program to improve the appearance of its poles, lines, substations and transformers.

Union Electric also participates in numerous cooperative research programs with its manufacturing suppliers and with industry groups. One of the most interesting at present is the work of Gulf General Atomic, Inc. on the gas-cooled fast breeder nuclear plant concept, a project in which Union Electric and a number of other electric companies are partners.

DX 149

Northern States Power Company - 1968 Annual Report

* * *

Although it was unfortunate that the Pathfinder nuclear reactor had to be prematurely retired at some considerable loss to the Company, the experience and know-how of our engineering and operating staff in the field of nuclear power has been extremely beneficial to us in connection with our major new nuclear projects. We feel also that the presence of nuclear power as a competitor has assisted us materially in controlling the costs of fossil fuels.

While managing our day-to-day operations and performing our jobs, we at NSP hold a vision of the future that inspires and challenges us. We see tremendous opportunities in the areas of climate control, transportation, improvement in the environment and living conditions. Imagine domed downtown areas and shopping complexes where the climate is electrically controlled the year around. Home computers will program and direct meal preparation. This is the high-energy society of tomorrow in which electric energy will bring us to new levels of comfort and achievement.

Projections show that all this will mean large increases in business for NSP. Our forecasts indicate that sales of electricity for the year 1972 will total more than 16 billion kilowatt-hours, compared with 12.5 billion kilowatt-hours in 1968. Projecting further, we anticipate that our total Company maximum demand for electricity will rise to more than 13 million kilowatts by 1990, compared with 2.7 million kilowatts in 1968.

As we move into this high-energy era, we are doing everything possible to build and operate our electric facilities so that they will make a minimum impact on the environment. NSP is in the forefront of air pollution control and abatement and will utilize emerging technology to further improve air quality. We are using the most modern design and equipment available to maintain water quality at our generating plants and are conducting continuing studies to assure that nature's balance is maintained. We are drawing on years of research by the Atomic Energy Commission and on the experience of NSP and other utilities to make certain that nuclear power plants present no danger to health and welfare.

In November, NSP and Minnesota Power & Light Company jointly announced the termination of negotiations concerning a possible corporate affiliation between the two companies. As discussions developed, it became clear that this was not a propitious time for an affiliation.

Among your management's most important responsibilities are the development of talent in the organization and constant evaluation of our personnel structure to meet NSP's changing and expanding needs. The broadening scope of our business brought management changes in May, 1968. Allen S. King, who had been Chairman of the Board since his retirement from active service in 1965, was elected Chairman Emeritus. I became Chairman of the Board and will continue as Chief Executive Officer. R. H. Engels, who was Executive Vice President, became President. E. A. Willson, formerly Vice President-Operation, became Executive Vice President, and D. W. Angland, who was Manager of Planning, became Vice President-Operation.

Henry T. Rutledge, President and Chief Executive Officer of Northwest Bancorporation, was elected to our Board of Directors in February, 1968, succeeding Kenneth N. Dayton. The stature of our Directors and their dedication to NSP's corporate citizenship are a great source of strength for the Company.

Bob Engels gives you an overview on the next few pages of the results of our 1968 operations. The pages following describe activities and accomplishments in more specific areas. I hope that you will read through the entire report, because it tells the story of an organization vitally involved in a changing world.

This report reflects the achievement of our entire employee force. We are dedicated to NSP's progress, and beyond that, to service to our fellow man. Our job is to bring a brighter life to those whom we serve. In that I sincerely believe we are succeeding.

March 7, 19

Sincerely,

Earl Ewald

* * *

Record demands by NSP's customers in 1968 called for an all-out effort by the Company's operating and construction forces. A winter maximum demand in power use was set at 2,319,782 kilowatts in January. But this winter record was easily broken early in the summer and four successively higher maximum demands were set as the summer wore on. Finally, the year's record was set August 23 at 2,701,359 kilowatts, a 16.3 per cent increase over the 1967 maximum demand of 2,323,383 kilowatts. At the time of the summer maximum demand, NSP was purchasing 196,000 kilowatts of capacity.

Good planning met needs

NSP had anticipated that kind of demand when planning was started more than four years before on the 580,000-kilowatt Allen S. King generating plant. The King plant

Feeding a thriving, power-hungry area

went into service well ahead of the 1968 summer demand, taking on its shoulders about 20 per cent of the Company's maximum demand. Smaller generating plants, recently built especially to help carry the load in peak times, also did their share in assuring NSP's traditionally dependable power. A 5500-kilowatt diesel generating plant at Albany, Minnesota was ready for winter peak duty in the fall. The Company started building a 69,000-kilowatt gas-turbine electric generating plant for peaking purposes at St. Cloud, Minnesota in 1968 which will be ready for service in May, 1969. A similar installation will be started in 1969 at Mankato, Minnesota to be completed by the spring of 1970.

The Company also announced plans to build a large generating plant on the Minnesota river near Jordan, Minnesota—not far from the Twin Cities—sometime in the late 1970's. The Company has been taking steps toward acquisition of a 2100-acre site in the area. No decision has been made yet on the size of the plant or choice of fuel.

'68 water power well above average

E. A. WILLSON
Executive Vice President

It was a good year for NSP's hydro-electric operations too, cutting NSP's power production expense. The Company's hydro plants turned out 7 per cent of the total energy generated by NSP during the year. This kilowatt-hour production was 25 per cent higher than our 20-year average annual hydro output.

Pathfinder to be converted to gas fuel

The Company made the decision in 1968 to convert the Pathfinder plant near Sioux Falls, South Dakota from nuclear fuel to gas fuel. The gas-fired boilers are now being installed at the plant so that the Pathfinder facility will be ready to generate 70,000 kilowatts of power by summer, 1969.

The Pathfinder nuclear plant had been shut down since September, 1967 because of mechanical problems associated with the reactor. Repairs and modifications necessary to resume nuclear operations would have cost as much as constructing the new gas-fired boilers and could not have been completed by the time power was needed from the plant in 1969.

As a result of the decision to terminate the nuclear portion of the Pathfinder plant, $9.5 million will be written off over a 10-year period. Contractual and technical aspects of the Pathfinder nuclear project are being reviewed by NSP with the contractor, Allis-Chalmers Manufacturing Company, and regulatory aspects of the plant are being reviewed by the Atomic Energy Commission.

Nuclear generating plant construction on schedule

Construction continued on schedule at NSP's 545,000-kilowatt nuclear generating plant at Monticello, Minnesota due for service in 1970. Public hearings were held in May by the Atomic Energy Commission on NSP's Prairie Island plant near Red Wing, Minnesota. Then, when the AEC granted its approval for that 1,100,000-kilowatt plant in July, construction activity picked up immediately. Completion of the first 550,000-kilowatt unit at Prairie Island is set for 1972 . . . the second for 1974.

Transmission lines will deliver power where needed

Many high-voltage transmission lines to speed power today and tomorrow to where it is

● Construction is on schedule at NSP's Prairie Island nuclear generating plant, where these workmen are installing a seal-lining cable for the construction derrick. The 200-foot-high cement "silo" will house the nuclear reactor for the first 560,000-kilowatt generating unit.

CHAPTER 3

FUELS AND FUEL TRANSPORT FOR ELECTRIC ENERGY

The electric power industry uses more than half of all the bituminous coal mined in this country, large volumes of natural gas and oil, and a growing amount of nuclear energy.

Fossil fuels were the basic energy source of 81 percent of the electricity generated in the United States in 1963. In order to meet the tremendous growth in the demand for electricity expected for the coming decades, our projections indicate that by 1980 the electric power industry will more than triple its 1960 demand for fossil and nuclear fuels and will be using annually some 500 million tons of coal, 4 trillion cubic feet of natural gas, 100 million barrels of residual oil, and 20 to 30 thousand tons of uranium for nuclear generation.

Fuel accounts for 15 cents of every dollar spent by utilities for electric power, with transportation comprising a significant part of the total fuel cost. The future demands for fossil and nuclear fuels involve such large quantities that competition and technological gains will most certainly result in reducing the cost of fuel at the source, and also the cost of moving it to market. Delivered fuel costs are expected to drop from a 1962 average national price of 26 cents per million British thermal units to 21 cents by 1980. These figures reflect anticipated reductions in fuel transportation costs and in some cases, the alternative of locating power plants at the fuel source and transmitting the electricity, rather than the fuel, to the load area.

This chapter reviews the major considerations affecting the supply and costs of fuels to electric utilities during the survey period. In making our appraisal of fuel supply and costs, we have drawn heavily on basic general energy studies conducted in recent years by Government and private sources and especially upon the reports submitted to the Commission by the Special Technical Advisory Committee on Fuels.

Total Fuel Requirements

The total use of fossil and nuclear fuel for electric power generation is projected to increase from 6,500 trillion Btu in 1960 to approximately 22,000 trillion Btu in 1980. The latter figure is equivalent to 900 million tons of coal with a heat content of 12,500 Btu per pound. The rate of increase of use for fuels projected by the electric power industry closely parallels the rate of growth we have projected in the National Power Survey; for 1980 both the loads and the fuel requirements are approximately 3½ times the 1960 level. Although the share of thermal sources (including nuclear) is expected to increase to 87 percent of total kilowatthours generated in 1980 as the share of hydroelectric power declines, continued progress in reducing fuel requirements per kilowatt-hour should offset the impact of the increased reliance on thermal sources.

The estimated total fuel requirements for thermal power generation, including nuclear fuel, by study areas is presented in table 20. These estimates reflect the reduced fuel requirements per kilowatthour of using the larger generating units with improved thermal efficiencies. The trend in fuel used in the typical area tends to follow the expected growth in the area's electrical loads. The major departures from this pattern occur in several areas of the Far West—L, N, O and especially P. These areas at present depend on hydroelectric sources for a major share of their generation but will become increasingly dependent on thermal sources for future growth as the availability of good undeveloped hydro sites diminishes. Some areas, of course, are expected to be moderate net importers or exporters of electricity generated at particularly favorable locations, including some mine-mouth alternatives and Canadian hydro. These sources are examined in chapter 15. The expected growth of fuel requirements therefore does not always coincide with the expected growth in load.

Fuel Availability and Use Trends

The overall outlook for fuel availability is favorable. We expect fuel supplies at prices close to present levels to be ample to meet the thermal electric demand for the life of generating plants installed by 1980.

[1] Includes nuclear as well as conventional thermal plants. Btu requirements for nuclear generation are estimated on the basis of the average heat rate for conventional steam.

[2] Excludes Alaska and Hawaii.

Source: Advisory Committee Report No. 21, prepared by the Fuels Special Technical Advisory Committee, Appendix 1, p. 315, Part II.

Table 21 compares the kilowatt-hours generated from each of the major energy sources in 1963 with estimates for 1980. The actual 1980 figures, and the market shares they imply will, of course, depend on the many hard-to-predict factors which affect interfuel competition. Whatever the precise shares turn out to be, it is clear that each of the fossil fuels will continue to supply both increasing amounts and an important share of a growing market, even though, as the table indicates, the percentage shares of the fossil fuels are expected to decline as a result of important nuclear fuel competition.

Coal, which presently supplies more than half of the market, will continue to be the workhorse for electric generation throughout the survey period, although its percentage share will decline from 54 percent to 47 percent, while natural gas should remain dominant in areas near sources of gas supply, although it can expect increasingly stiff competition elsewhere and on a nationwide basis its share will also decline from the 21 percent of 1963 to 17 percent of 1980. Oil will, in all likelihood, remain confined to coastal areas having access to cheap water transportation, where its share will depend to a large extent on the availability of imports at competitive prices. Overall, it is expected that oil, while more than doubling its volume, will decline on a proportionate basis by a third, from 6 percent to 4 percent of the market. Nuclear fuel will skyrocket from negligible current use to about 19 percent of the 1980 market.

Interfuel Competition

The choice between competing fuels depends not only on delivered prices but on many other factors

as well, including the relative thermal efficiencies of different fuels and differences in capital costs of generating plants equipped to burn particular fuels. The following statement by the Fuels Committee sums up some additional considerations:

> In determining the type of fuel to be used for electric generation, there are a number of factors to be reviewed and evaluated. Each of these has a bearing on cost and influences the degree to which an electric utility is able to meet its obligation to provide reliable service at a reasonable price. The costs of storing, handling, and in some instances, disposing of the fuel product are economic factors which can make a low-cost fuel the most expensive fuel. In locations where land costs are high and areas heavily congested, these costs become a major consideration in selecting a proper fuel. In some areas, operating conditions, such as air control regulations on the West Coast, may justify a premium fuel. Therefore, while a general picture can be drawn concerning the availability and price of fuels, the final determination in selecting a fuel or fuels for a particular plant must be based on the specific facts pertinent to that plant and its location.[1]

Relative delivered price per Btu is usually the overriding factor in competition among the fossil fuels. The choice of fuel is an integral part of the selection of a plant site but often competition between fuels may occur after a plant is in operation. Many stations are initially designed and equipped to burn alternative fuels interchangeably upon short notice, and stations originally designed for coal can usually be adapted to use gas or oil. Likewise, some gas or oil-burning plants can be adapted to use coal, but unless the plant was originally designed with this in mind, the conversion may be expensive. In many locations the competing positions of alternative fuels are very close, and a price reduction for any one fuel may trigger competitive reductions in other fuel prices.

While the fuel with the lowest delivered cost usually sets the pace for competition, the delivered prices at which fuels become competitive are not always identical. For instance, a coal-burning plant typically requires 10 to 15 percent more capital investment—chiefly in coal and ash handling equipment and more expensive boiler design—than a comparable plant which is not so equipped. However, this differential has a significant effect on interfuel competition only where gas and oil supplies are adequate to serve the plant's entire fuel requirements throughout its service life. Thermal efficiencies, which vary between different grades of the same fuel as well as between different fuels, also affect the relative prices at which fuels are competitive. Coal typically requires some 3 to 5 percent fewer British thermal units per kilowatt-hour than gas, with oil occupying an intermediate position.

[1] Advisory Committee Report No. 21, p. 317 of Part II.

Interfuel competition is expected to intensify in the future, particularly in the higher fuel cost areas, where improvements in energy transportation and the reductions in the costs of nuclear power should bring fuel costs closer to those of the lower fuel cost areas. Just as nuclear technology is shooting at a continually moving target in attempting to overtake conventional steam-electric generation, nuclear technology in turn is expected to set a continually lowering cost target which the fossil fuels and their modes of transport will be forced to meet.

Coal

Widely varying assessments of coal supplies are available depending upon the purpose and the nature of the investigations. The most recent official Department of the Interior estimate for all types of coal is that "recoverable reserves" in the continental United States, excluding Alaska, amount to 830 billion tons.[3] By comparison the projected energy requirements for thermal electric generation for the year 1980 is equivalent to 900 million tons of coal, of which nearly 500 million tons are expected to be in the form of coal.

The estimates of coal reserves can be misleading. While total reserves are more than adequate to meet any foreseeable demands by the electric utility industry, extensive tracts of coal lands adapted to low-cost mining techniques are by no means unlimited. A better inventory of our low-cost coal reserves than is now available would be of great value in industry planning.

The wide distribution of coal reserves throughout the United States is shown in figure 27 which depicts the "recoverable reserves." It is not generally realized that more coal lies west of the Mississippi River than to the east, although some 60 percent of the higher bituminous grades are found east of the Mississippi. While the western coals can be mined at low cost, they have not been extensively exploited to date, because of their distance from major load centers. Later chapters in the National Power Survey explore the possibilities of utilizing the abundant low-grade coals in the west.

Coal costs and prices at the source vary greatly with geologic conditions, methods of mining, required degree of quality control and many other factors. In order to determine the at-source coal

FIGURE 26 *A twin boom continuous mining machine moves between working places in a West Virginia coal mine. These massive and costly machines typify the bituminous coal industry's drive to hold or reduce the price of coal in the face of rising costs. This machine rips coal from the face of the seam and passes it back to the conveyor belt or shuttle cars at a rate of up to 8 tons a minute, eliminating the separate operations of cutting, drilling, blasting and loading.*

prices for large volume utility coal customers, the Fuels Advisory Committee enlisted the cooperation of 20 selected electric systems which purchased over 45 percent of all coal used by electric utilities in 1961. The average price f.o.b. the mine paid by these systems ranged from 12½ cents to 16½ cents per million Btu and averaged 15 cents per million Btu. 1961 prices in the several coal-producing districts are shown in the Advisory Committee's report.[4]

Coal-mining productivity has more than doubled in the past decade from an average of 7.5 tons per man-day in 1952 to 15.4 tons per man-day in 1962, an almost unprecedented productivity improvement for a mature industry. This represents an accelerated rate of improvement over prior years which, if continued, augurs well for the future competitive position of the coal industry. Continued mine mechanization including the use of large shovels such as the one shown in figure 28, more intensive mining machine utilization, improved haulage systems and the development of mines designed specifically to supply the electric power market are factors operating to lower future coal costs at the mine. Mining conditions, changes in wage rates and the costs of competitive fuels can also alter future prices at the mine.

DISTRIBUTION OF FOSSIL FUEL RESERVES

FIGURE 27

FIGURE 28 *Huge machines, such as this electric powered 115 cubic yard strip shovel, operated by the Peabody Coal Company in its strip mines near Paradise, Kentucky, are contributing to the continued reduction in the cost of mining coal.*

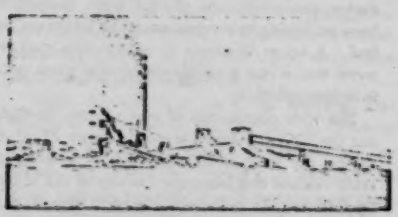

FIGURE 29 *Coal storage yards at coal-burning steam-electric plants contain 4 to 6 months reserve supply of fuel. The stockpile is placed in layers and compacted to prevent spontaneous combustion. The storage yard is equipped with an extensive system of conveyor belts for unloading, stocking and delivering coal to bunkers.*

In general, the outlook is for stable to moderate reductions in the f.o.b. mine prices with further lowering in delivered costs through broad application of volume movements by highly efficient rail and other transport facilities.

Natural Gas

Proven recoverable reserves of natural gas in continental United States, excluding Alaska, approximated 276 trillion cubic feet at the beginning of 1964, equivalent to about 11 billion tons of high

grade bituminous coal and enough to last about 19 years based on 1963 net production of 14.7 trillion cubic feet. The proven reserve figure, however, is a conservative estimate of the reserves already discovered which can be appraised with a high degree of accuracy, and which are recoverable under current economic and operating conditions. There is no comparable estimate of coal reserves.

Estimates of the additional gas that may ultimately be discovered and produced range from 2 to 10 times the 1964 proven reserves of 276 trillion cubic feet. In addition, we are already importing gas from Canada which has 36.7 trillion cubic feet of proven reserves and there is an immense potential for the discovery of additional gas reserves in that country. Alaska, where exploration has just begun, already has an additional 1.7 trillion cubic feet of proven reserves.

Natural gas reserves are heavily concentrated in five States—Texas, Louisiana, Oklahoma, Kansas, and New Mexico (see fig. 27). This contiguous area accounts for over 88 percent of proven reserves in the continental United States excluding Alaska. While the Geological Survey estimates that most of the United States is favorable for the discovery of natural gas and oil reserves, it is expected that the major portion of new reserves to be found and developed between now and 1980 will be in or near the areas in which reserves have already been found.

Electric utility consumption of natural gas has increased at an average annual rate of 11½ percent during the past three decades. This extraordinary growth reflects the dynamic growth of the natural gas industry, especially since World War II as the extension of natural gas pipelines from the major gas producing areas to every State in the Union other than Maine and Vermont has made natural gas available in many new markets throughout the country. Electric utility purchases, frequently under contracts which provided that service could be interrupted when the pipeline required the gas to serve other customers, contributed to the economic feasibility of pipelines by providing markets in the summer and other periods when residential gas demand is not at its highest and by helping justify the installation of larger and more economical pipelines than would otherwise be needed in advance of growth in residential demand.

During the most recent decade, 1953–63, natural gas consumption for electric generation has increased at an annual rate of approximately 7.5 percent, with the share of total thermal generation supplied by natural gas increasing from 24 to 27 percent during the same period. Large scale extensions of pipelines to new areas continued to be important during the past decade as, for example, in California, where electric utility consumption of natural gas, the local supply being augmented by new pipelines from the Permian and San Juan Basins of Texas and New Mexico, more than tripled. New pipelines were also a factor in the West Central Region (FPC Region VI), the second most important growth area. Another significant factor influencing gas consumption in both areas has been a sharp increase in the share of total generation supplied by fuel burning steam plants and the corresponding decline in the portion of total loads supplied by hydroelectric power. Natural gas is now available in 46 of the 48 contiguous States, and in 43 of these gas is used to some extent for electric generation.

Table 22 presents projections of future electric utility gas consumption developed by the Commission's Bureau of Natural Gas in cooperation with the Fuels Advisory Committee. The projection of 4 trillion cubic feet of gas for electric generation in

TABLE 22

Consumption of Natural Gas by Electric Utilities
(Trillions of cubic feet)

FPC Regions	Actual	Estimated

1980 is twice the 1962 usage. A detailed account of the basic assumptions and analyses underlying the projections appears in the report of the Fuels Advisory Committee No. 21, p. 315 of Part II.

FIGURE 30 *A link in America's network of major natural gas pipelines is coated and wrapped for extra protection against corrosion before it is placed in the trench. The 190,000-mile network provides the nation with a transport system for the economic supply of natural gas to many areas and for many purposes including its use as primary or interruptible fuel for steam-electric generating stations.*

The projections of future gas consumption by electric utilities, table 22, are based purely on market trends. These projections do not reflect any policy decisions by the Federal Power Commission on the use of gas for boiler fuel and are not intended to imply any prediction of future Commission policy in exercising its regulatory responsibilities in this area.

In table 22 Illinois and Wisconsin are grouped with FPC Regions I, II, and III because they are similar to the other States in those regions in their predominant use of coal as fuel for electric generation. In those areas, it is expected that most of the gas used for future electric generation will be on an interruptible basis. Competition from coal and from nuclear fuels and the expiration of old low-priced gas contracts are likely to prevent a significant net increase in electric utility gas consumption in this section of the country.

Region VI, and the portion of Region IV west of the Mississippi, represent a mixed fuel area with varied competitive situations and generally low delivered gas costs. Gas is projected to maintain its share in this area. The major market for fossil fuels in the Far West (Regions VII and VIII) is in Region VIII which includes California, Arizona, and Nevada, a high fuel cost area in which gas is now the dominant fuel for generation. The projected slowdown in the growth of the boiler fuel market during the 1970's largely reflects the expectation of nuclear competition.

In Region V—the South Central Region—which includes over 90 percent of the Nation's known gas reserves, gas has a substantial competitive edge. However, some load centers are closer to deposits of coal or lignite than to the closest gas fields, and the economic attractiveness of these competitive sources is increasing. The projection for Region V assumes that gas will be the source of 80 percent of the total generation in the region in 1980, and that more than half of total boiler fuel sales of gas will be concentrated in this region.

Interfuel competition, primarily with coal, is expected to limit increases in the cost of natural gas for electric generation to about the present levels in most sections of the country. In the gas producing areas, however, natural gas enjoys a substantial current price advantage with respect to other fuels and thus could increase in price without materially affecting its competitive position. Comparison of the present price of gas in any particular location with limiting prices of competing fuels provides a rough measure of the extent to which the price of gas for power production has room to increase.

Oil

Residual oil, the only fuel oil used in significant quantities for electric generation in the United States, is an oil refinery byproduct which remains after the more valuable refined liquids have been extracted and solids have been removed. Since it is a byproduct, residual oil is supplied in amounts which depend primarily on the market for other refined oil products. Residual is only a small proportion (9.6 percent in 1962) of the total barrels of refined oil products produced domestically, and

nearly one-half of U.S. residual oil consumption is supplied by imports. The availability and price of imported residual depends on U.S. import restrictions as well as the world supply and demand for petroleum products.

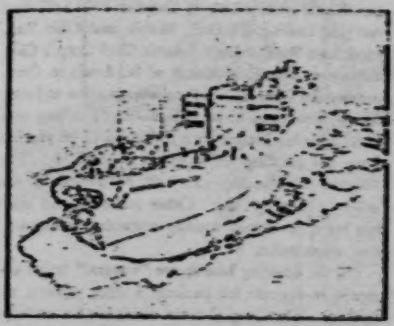

Figure 31 This ship, typical of the modern super-tanker, which carries crude oil to Atlantic Coast ports from southeastern producing areas and crude and residual oil from foreign ports, has a cargo capacity of 66,000 long tons and a draft fully loaded of 42 feet. Refinery residual oil is used extensively as fuel for steam-electric plants along the Atlantic, Gulf and California coasts.

Residual fuel oil finds its market along the east and west coasts together with some of the areas bordering the major inland waterways. Residual oil can compete with other fuels only where waterborne transport is available. In much of this area, however—especially in the northeastern United States—it provides a competitive influence that would not otherwise exist and thus operates to reduce prices of other fuels to the benefit of the consuming public. Residual oil is purchased by the barrel and a barrel roughly equals one-fourth of 1 ton of coal in heat equivalent. The current average price is approximately $2.10 a barrel, the equivalent of 35 cents per million Btu. In 1962, residual oil was used to produce about 7 percent of total thermal electric generation, but it constituted 27 percent of the fuel used for generation in the Northeast (FPC Statistical Region I).

U.S. import policies are an important factor in the consumption of residual oil by electric utilities as well as other users. A policy of easing import restrictions could be expected to intensify interfuel competition and possibly expand the area within which residual oil competes with other fuels. The effect upon the use of other fuels would depend upon the ability of the various fuels to counter residual's lower price. The overall merits of such a policy depend on complex considerations involving many aspects of the national interest which are beyond the scope of this Survey. The dependence of residual oil availability and price on our international and domestic policies and on world oil markets sets this fuel apart from the other fossil fuels in that it is less amenable to accurate projection based on normal reserve calculations and economic and technological factors. Our projections that residual oil will supply a somewhat smaller share of the market in the future reflect the possibilities of appreciable reductions in the cost of using coal and nuclear energy.

Nuclear

According to the Atomic Energy Commission "reasonably assured resources" of uranium and thorium have a total energy content of more than 94,000 Q [4] but with the existing technology of mining and concentrating nuclear materials only 3/10,000 of this total or 28 Q, could be mined at current cost levels. For comparative purposes, the annual basic energy consumption of the United States (coal, oil, gas and hydro) is about 0.05 Q and recoverable fossil fuel resources are estimated at 15 to 20 Q [5] but may be much higher. Of this amount, perhaps 6 Q is available at current costs.

While the estimate of 28 Q of nuclear fuel represents a very large reserve, the discussion of nuclear fuel resources can be misleading unless we consider the low efficiency with which nuclear fuel is now utilized and the prospects for improving that efficiency. Present reactors utilize nuclear energy with an efficiency of only about one percent of the potential energy in nuclear fuel. As a practical matter no energy is presently realizable from thorium reserves (about 6 Q of the 28 Q). In total,

---

[4] A "Q" is a billion billion (10^{18}) Btu, and corresponds to the heat content of about 40 billion tons of high grade coal.

[5] Total recoverable coal reserves for the continental United States excluding Alaska are estimated at 850 billion tons, equivalent to about 15 "Q", but this assumes only 50 percent recovery. Proven oil and gas reserves estimated on a much more conservative basis represent about 1 "Q".

the nuclear energy obtainable with present technology from uranium minable at about current costs thus represents less than one Q rather than 28 Q. While this is only a portion of the ultimate nuclear potential, it is still several times as large as the projected use (at existing efficiencies) of nuclear plants built during the survey period and the technology can be expected to make much larger reserves available during this time. A further discussion of nuclear fuel reserves and the effects of high converter and breeder reactors on more efficient use of these resources is contained in chapter 5.

Fuel Transport Cost

Important reductions are being made in the transportation costs of all fossil fuels but the most impressive developments in recent years and in prospect for the near future relate to the transportation of coal. Further, transport costs account for a much larger proportion of the delivered fuel costs for coal than for natural gas and oil. For these reasons the following discussion of transportation costs is largely related to the movement of coal.

Railroad Transport

Coal is the largest single item of railroad traffic. Three-quarters of all coal tonnage shipped in 1962 utilized rail transport for part or all of the movement from mines to consumers. Coal shipments represent close to 40 percent of the freight tonnage and produce about 25 percent of the revenues of Eastern District railroads, which serve the major coal fields east of the Mississippi River.

After World War II, railroad freight rates on coal increased and the total tonnage of coal shipments by rail began to decline. In the late 1950's, the railroads reversed this trend of rate increases and began to adopt low rates for volume movements in an effort to increase tonnage. More recently, the railroad industry, with the approval of regulatory agencies, has adopted still lower "trainload" rates and in cooperation with electric utilities has been exploring new coal transport arrangements to lower costs and effect major reductions in rates for large movements of coal. Increasing competition from barge lines, the perfection of coal pipelines and the emergence of nuclear energy as an added competitor have been major factors spurring railroad action to reduce rates.

An important new development is the "unit" train operating between a single mine and a single generating plant with special equipment and tight scheduling of loading, unloading and movement, and often employing utility owned coal cars. A recent example of such an arrangement is the 126-car shuttle train which in October 1964 will start carrying coal on the Gulf, Mobile and Ohio Railroad from Southwestern Illinois Coal Corp.'s Captain mine located southeast of St. Louis to Commonwealth Edison Co.'s generating station at Joliet, Ill., a distance of about 300 miles. The new rate of $1.30 a ton represents a reduction of 49 percent from the existing rail-barge rate of $2.56. The 100-ton swivel-dump cars will be owned by the utility. (See fig. 32.) Other railroads and utilities have developed equally attractive transportation movements.

On the drawing boards are "integral" trains designed to operate for perhaps a week without refueling. The integral train consists of very large cars permanently coupled to power units interspersed among the cars. The cars are designed for rapid automatic unloading and are insulated and heated to avoid the problem of frozen coal. Integral trains will operate at passenger train speeds with remote control of all features from the head of the train. Train capacity would be about 35,000 tons in contrast to today's big trains of 7,000 to 10,000 tons. A control car at each end of the train would permit shuttle service without the necessity for turning at either end of the run. A key factor in the integral train's economy is its short "turn around time" from loading at mine to unloading at power plant and return, with major savings in the fixed charge component of cost.

The availability of sharply reduced freight rates for large volume movements of coal to steam generating plants has added a new and very large additional element of savings realizable in providing generating capacity in large units and stations. Larger generating units are more efficient and less costly per kilowatt in themselves. But the savings in coal transportation rates from the volume movements they make possible provide additional savings which are perhaps just as large or in some cases even larger than the savings in the cost of generation.

Volume movements and improved techniques of coal transportation can be expected to permit substantial reductions in railroad rates for coal by 1980. Figure 33, based on the study by the Fuels Com-

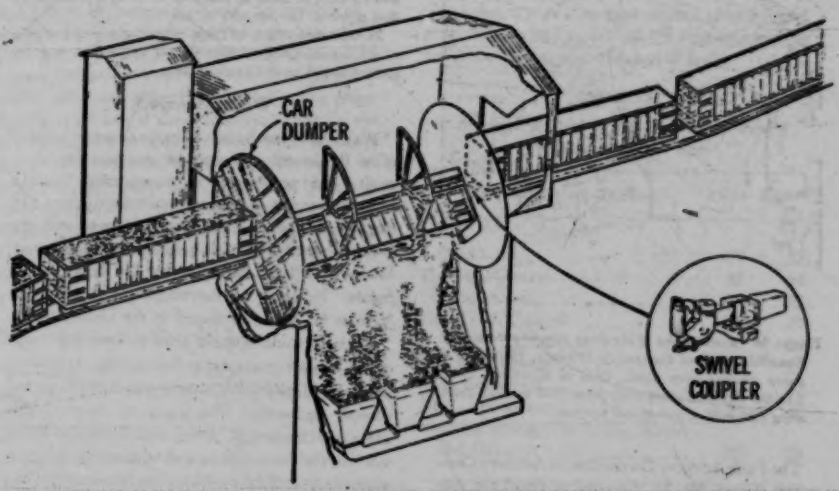

FIGURE 32 *Unit Train of the Commonwealth Edison Company is typical of newly developed specialized trains which can move coal from the mine to large power stations at greatly reduced costs because of simplified operations and shortened round-trip elapsed time. Each of these trains can carry in the order of 12,000 tons of coal.*

mittee, compares 1963 rates with the Committee's 1980 projection, and shows the large reductions in rail rates already in effect on volume movements of coal and the even greater reductions expected by 1980. With a high degree of automation even lower costs may be possible during the Survey period.

Pipeline Transport

The technology of pipeline transport for oil and natural gas is well developed and highly efficient. Some improvement in economy is possible in the future with the use of pipe of larger diameter and of greater strength to permit higher pumping pressures.

A new development which has excited much interest is the movement of coal in slurry form by pipeline. The successful operation of a 108-mile-long coal-slurry pipeline in the 6-year period 1957–63 has demonstrated the economic and technical feasibility of this method of coal transport. (See fig. 34.)

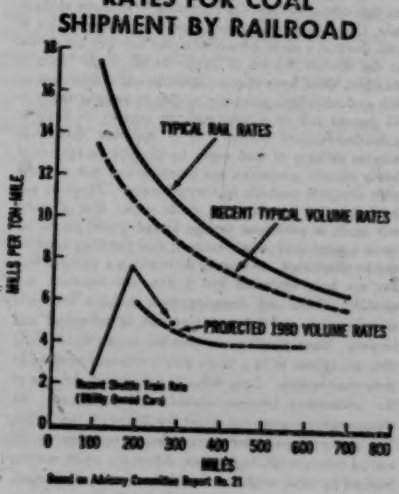

FIGURE 33

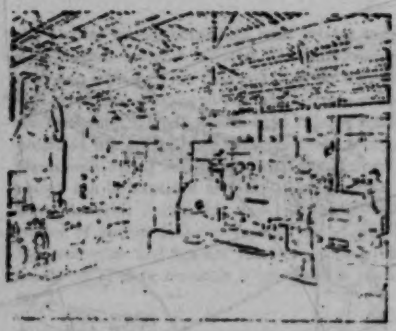

FIGURE 34 *View on one of the three pumping stations on Consolidated Coal Company's 108-mile, 10-inch, coal slurry pipeline from Cadiz, Ohio to Cleveland, Ohio. The line operated successfully from 1958 to 1963, delivering 1.25 million tons of coal per year.*

The Fuels Advisory Committee, in Advisory Committee Report No. 21, discussed in detail the considerations affecting a utility's choice of a coal pipeline *vis a vis* other modes of coal transport and summarized its findings as follows:

After moving over 700 million ton miles of coal, cross-country shipment of fine coal has been amply demonstrated on Consolidation Coal Co.'s pipeline from Cadiz to Eastlake, Ohio. A successful demonstration of direct firing of coal slurry in a cyclone burner furnace has been conducted at the Warner Station in South Amboy, N.J. Tests at Eastlake, Ohio, have demonstrated the use of filter-pulverizer and centrifuge pulverizer system to dewater slurry to 22 percent and 18 percent moisture content for firing in pulverizer-furnace burner. It is apparent that large volume delivery of coal slurry by pipeline to centers of heavy electric generation are practical and can compete with alternate methods of transportation. Pipelines can be designed to handle lower grade coals. Use of slurry will result in additional savings at new power plants because a great deal of conventional coal handling facilities can be eliminated. Storage of inventory is a problem that has not been optimized but it does not represent any obstacle. Tests and demonstrations indicate that coal slurry can be used for cyclone as well as pulverized coal burners. Since pipelines are installed underground, there does not appear to be a major public relations problem in their construction. Once a line is constructed, because of the relationship between variable and fixed costs, the transportation component of cost should remain very stable. This protects against inflationary factors but deprives the user of future technological cost reductions which may be realized by other methods of coal transport. At present, there are legal problems in obtaining right-of-way. Every effort should be made to eliminate these legal problems so that pipelines can compete on merit.

In the construction of large electric generating plants of the future, transportation of coal by pipeline must be given full and careful consideration.

Water Transport

Water transport by inland barge or ocean vessel is often the lowest cost mode of transport for oil or coal. The possibilities of transporting liquified natural gas (at a temperature below minus 116 degrees Fahrenheit) are being explored and the technical feasibility of this form of transportation has already been demonstrated for ocean movements. However no movements of liquified gas have so far been introduced in the United States.

Costs of transshipment tend to limit the availability of water transport to fuel sources near waterways and to generating stations which can be served directly by water. The waterway developments along the Mississippi, Ohio, and Tennessee River systems, the Great Lakes, and at coastal points provide many locations which can be served by the water carriers. (See fig. 35.)

A key element affecting the costs of water transport is the limitations which the physical characteristics of our waterways impose upon the barge or vessel. For example, the sizes of individual barges

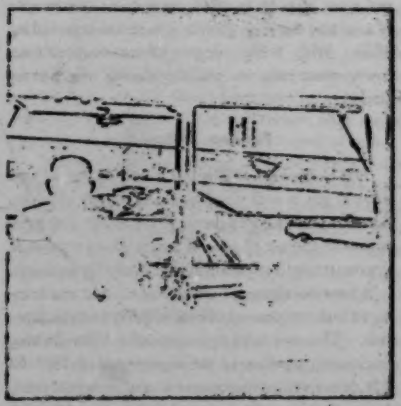

FIGURE 35 *Slack water barge navigation on the Nation's network of developed waterways economically moves large tonnages of coal to dock-side power plants.*

and groups of barges or "tows" (propelled by a single tow-boat) are controlled by the size of the locks and depth of the navigable channels. The outlook for lower rates on shipments by barge on the inland waterways is therefore limited by the physical characteristics of the waterways which do not lend themselves to ready expansion of tow sizes and quick turn-around equipment. However, increased tonnage on our waterways, larger locks, and stiffer competition from the railroads are factors which suggest that lower rates may be in the offing. Reductions in coastal coal and oil transport rates through use of special barges and tugs are also possible.

Transmission of Electric Energy

An alternative to the transport of fuels from their sources to electric generating stations is the transmission of electric energy at high voltage from generating stations located near the fuel sources. It will suffice here merely to point out this alternative. The technical and economic considerations affecting this choice are discussed in chapters 9 and 10. Indications of the manner in which this alternative is likely to develop during the next two decades are given in chapter 15.

Comparison of Delivered Energy Costs

Table 23 presents, region-by-region as well as for the Nation as a whole, the average cost of fossil fuels delivered to electric generating plants in 1962 and an estimate for 1980. The estimates for 1980 reflect the influence of such factors as an increasing proportion of mine-mouth as opposed to load center generation as well as anticipated improvements in the cost of mining and transport of fuels.

Conclusions

It is impossible to predict the combined effect of the considerations discussed in this chapter with respect to each fuel and each mode of fuel transport, including the alternative of electric power transmission. Nevertheless, as table 23 indicates, it would appear that we can expect a downward trend in the delivered cost of fuel in most locations.

CHICAGO SUN-TIMES

October 19, 1967

Pages 1, 4

DEFENDANT'S EXHIBIT 151

Chicago's Dirty Air —A Growing Peril

Because air pollution is a growing threat to the health of every Chicago area resident, The Sun-Times assigned medical writer Dick Kirschten to conduct an intensive investigation into the problem.

While looking into the causes—and possible cures—of Chicago's filthy air, he interviewed scores of government officials, medical and scientific experts, and just plain angry citizens.

The first of his reports is presented today.

By Dick Kirschten

Those teary-eyed residents of smog-shrouded Los Angeles are breathing cleaner air than we are here in Chicago, according to the U.S. Public Health Service.

*U.S. Public Health Service

In fact, the PHS report issued last summer rates the Chicago area's air pollution problem as the most severe in the country, with the exception of New York City where the air has been described as the filthiest in the world.

At that, Chicago is ranked even worse than New York and other cities when it comes to spewing poisonous and corrosive sulphur dioxide gas into the air.

And sulphur dioxide, as defined in the Medical World News, a leading professional magazine, is "(a) poisonous (which can) cause chest constriction, headache, vomiting, and death from respiratory ailments."

The reason that Chicago's air is full of sulphurous gases is no mystery.

According to the PHS estimates, more than 11,500,000 tons of pulverized soot and sulphur are shipped across the prairie each year in the form of soft coal from the mine-fields of southern Illinois.

U.S. Bureau of Mines statistics show that nearly two-thirds of Illinois' coal production falls into the category of "high sulphur content." The remainder falls into the "medium sulphur" range.

None of the coal mined in the relatively nearby southern Illinois and western Kentucky fields qualifies as low sulphur fuel—fuel is, having a sulphur content of one per cent or less.

At this soft coal is burned in the six-county Chicago metropolitan area each year, 1,671,000 tons of sulphur dioxide gas are belched into the atmosphere, the PHS says.

City of Chicago figures show that 3,000,000 tons of coal—nearly all of it the southern Illinois variety—are burned within the city annually, producing more than 300,000 tons of sulphur dioxide gas.

Commonwealth Edison's generating plants burn two-thirds of this soft coal, the city figures show. The city's next largest category of coal consumption is residential heating, which accounts for about 1,200,000 tons annually. Industrial and commercial sources combine to burn another 1,500,000 tons.

Methods for removing sulphur dioxide from smoke and stack gases are still considered experimental and are not in common use. None of the coal burned in Chicago is subjected to any sulphur dioxide controls.

Chicago's air pollution ordinance places no restrictions on either the sulphur content of fuel or the emission of sulphur dioxide gas.

Other cities, notably New York and St. Louis, recently have enacted restrictions in an effort to clear their air. Los Angeles has had rules controlling the emission of sulphur dioxide since 1948.

Sulphur dioxide is an invisible gas. Most Chicagoans are visually quite aware that the area also is plagued by more obvious forms of air pollution.

Ordinary specks of dirt in the air—the air pollution professionals call them "suspended particulates" — also contributed to the Chicago area's low ranking.

Among the 88 metropolitan areas compared in the PHS

report, Chicago tied for seventh place when it came to concentration of particles of dirt in the air.

Much of this "particulate" matter is "fly ash," which also stems from the burning of coal. Other prominent sources of the ash are steel-making and the incineration of the vast amounts of garbage discarded each day.

Auto Biggest Offender

In terms of total volume of urban air pollutants, the biggest offender by far is the auto.

Pollution from cars was the third element in the PHS survey. The metropolitan areas were compared on the basis of gasoline consumption.

In terms of total gasoline consumption, Chicago ranked third with a total of 1.9 billion gallons. On the average, it was calculated that $12,000 gallons of gasoline are burned every year for each square mile in the six-county area.

Chicago's over-all low standing seems a rather dismal progress report when you consider that the city's efforts to abate air pollution date back 98 years. In 1874 — just three years after the smoke from the Great Fire had cleared—a citizens' association was formed to seek smoke control legislation.

In 1881, Chicago passed the nation's first civic air pollution ordinance, complete with a penalty clause.

Today, Chicago, has a highly regarded air pollution control program, replete with such modern electronic refinements as automatic air samplers, computer systems and a "spy in the sky" remote-control television camera.

More than 15 million tons of coal are burned in the six-county Chicago metropolitan area each year, releasing 1,071,000 tons of sulphur dioxide gas in the atmosphere.

Chicago area vehicles burn 1.9 billion gallons of gasoline each year. Exhaust air pollutants come from some $12,000 gallons of gas used for each square mile.

Children on their way to school pass steel mill chimneys at 87th and Burley that pour out black smoke to add to Chicago's air pollution menace. Factories throughout city contribute to dirty air build-up. (Sun-Times Photo)

William J. Stanley, director of the city's program, describes the PHS ranking as "a grossly inadequate comparison." He also is quick to point out that the report refers not just to Chicago, but to the six Illinois counties of Cook, Du Page, Kane, Lake, McHenry and Will.

Two neighboring Indiana counties, Lake and Porter, which often have been implicated as contributing to Chicago's air pollution problem, were ranked separately. These counties, containing the steel mills of the Gary area were rated as having the nation's 11th most severe air pollution.

The authors of the PHS report concede their rankings are a rather "rough measure of the true severity of overall pollution problems."

Some pollution levels used in the calculations were projected for an entire metropolitan area on the basis of measurements taken at a single spot. Other levels are based solely on fuel consumption data rather than on actual measurements of pollutants in the air.

Weather Variations A Factor

A factor was included in the ratings to allow for weather variations from area to area which can profoundly affect the severity of the local air pollution situation. Los Angeles, for example, was penalized because of its unique propensity for long periods of air stagnation.

Despite all the qualifying factors, the rankings were issued with a statement expressing the conviction that "the list of cities arrived at gives a good over-all indication of the relative severity of their air pollution problems."

In other words, the U.S. Public Health Service is convinced that there is plenty of trouble in the air in Chicago—much of it in the invisible form of sulphur dioxide gas.

ANTIPOLLUTION, ANTITRUST BILLS ARE SIGNED BY GOV. OGILVIE

Sun-Times Bureau

SPRINGFIELD, Ill.—Gov. Ogilvie Wednesday signed into law bills giving Atty. Gen. William J. Scott new powers to move against water and air polluters and a strengthened hand in antitrust actions.

Under the antipollution measures, the state receives the power to seek court action closing down polluters throughout the state.

In addition, fines for polluters are increased from $500 to $5,000, and jail terms hiked from 30 days to six months.

"Signing of these bills gives Illinois the toughest antipollution enforcement laws in the United States," Scott said in a statement.

One bill gives Scott power to enforce antipollution standards in Cook County. Previously, the Chicago Sanitary District and the city and county air pollution boards had exclusive enforcement jurisdiction.

Scott noted the antitrust legislation requires all state agencies to report two or more identical bids for investigation of possible collusive bidding.

In addition, he said, the new law gives him wide powers to move against price fixing and criminal infiltration of legitimate business.

Crackdown on air pollution!

Atty. Gen. William J. Scott has said he'll use strong new state powers to curb air pollution when cities fall down on the job. Good for him.

The air in Chicago, and other Illinois cities, too, is full of filth and there is precious little being done to purify it or even to make it moderately fit to breathe.

Chicago in particular has shown a reluctance to proceed against polluters despite an anti-pollution code adopted last year.

Last month, the City Council granted a year's delay in enforcement of limits on sulphur dioxide emission — which results from burning coal with a high sulphur content. Last week, the air pollution control appeal board found four steel firms to be behind schedule in agreed-to reduction of air pollutants. The firms were told merely to send in more frequent reports and to file them individually, rather than as a group.

There is no longer any excuse for softness toward those who befoul the atmosphere. Air is the stuff people breathe to live. When it is filled with noxious substances these are the things that enter people's lungs.

The Legislature gave the attorney general strong powers. They include injunctive power to close down plants that do not comply with state anti-pollution standards, and they include the power of criminal prosecution.

We welcome Scott's pledge that he will employ these tools, and hope his 25-man anti-pollution task force has good hunting. Anything that will bring polluters into line should be done — however harsh.

EDISON CUTS USE OF COAL, REDUCES AIR POLLUTION

By John Adam Moreau

The Commonwealth Edison Co., major contributor to air pollution in the Chicago area, reported it markedly reduced its burning of coal Monday.

A sharp drop in pollution was noted between early morning and midafternoon.

The company took the action on the fifth straight day of heavy smog.

As it did, the Businessmen for the Public Interest wiled a petition with the Illinois Commerce Commission saying Edison is guilty of "environmental violence" and should not be allowed the 6.1 per cent rate increases it seeks.

The commission is scheduled to begin a series of cross-examination hearings on the rate request, the first set for Wednesday.

The reduced burning of coal by Edison was important because the firm, according the city Department of Air Pollution Control, usually burns enough coal to create two-thirds of the sulphur dioxide pollution in Chicago.

Over-all, said William J. Stanley, the city's Air Pollution Control director, the generating of power causes one-fifth of the city's air pollution and Edison most of that one-fifth.

(The other over-all causes, each about one-fifth, are motor vehicles, refuse burning, space heating and other industry, said Stanley.)

Robert Lundberg, Edison's general staff engineer, said the company's action Monday means this:

Only 10 per cent of power for Chicago was being generated in Chicago; and 5 per cent of that power was created by coal burning, 5 per cent by natural gas. Ninety per cent of the power requirements came from generating plants outside Chicago, including facilities in Stickney, Downstate and in Wisconsin and Iowa.

These facilities burn coal, he said.

Lundberg said that he would confer with city officials Tuesday morning about restoring normal operations, providing the air has cleared sufficiently.

Meanwhile the Weather Bureau predicted that the conditions which have aided the air stagnation are beginning to change.

Weathermen said the high pressure system, which has been hanging over the area since Thursday, began inching eastward and fresher air began drifting in from the South.

Even the pollution statistics began to change. An early morning sulphur dioxide level of .25 of a part per million parts of air—2½ times above the danger level—eased down to .08 of a part by midafternoon.

Lundberg said Edison's action was taken on request of the city. He also said power was generated outside Chicago from Thursday afternoon through Friday morning, when coal burning was reduced.

Because power demands were less, the usual coal burning process was used Saturday and Sunday, Lundberg said.

The petition to the commerce commission, filed by attorney Joseph Karaganis, defined "environmental violence" as "the gross degradation of a natural environment with resultant damage to the medical and esthetic health of the community."

The businessmen's group is composed of a number of wealthy Chicagoans. Among its founders seven months ago was Gordon Sherman, president of Midas-International Corp.

Their petition stated, "Commonwealth Edison Co. could substantially reduce the amount of emissions of both sulphur dioxide and particulate matter. Low-sulphur coal is available in quantity. Devices are available which are

much more effective than those now used by Edison to trap particulate matter."

Asked why Edison cannot always use natural gas, Lundberg replied that not enough natural gas is available for Edison's needs. Asked whether, if Edison made it a policy to use natural gas, suppliers could accommodate their operations and stock enough, he said he doubted it.

He added that so far as he knew Edison never has tired to figure out whether it would be possible to switch to natural gas. The company expects to produce about 40 per cent of its power by means of atomic energy by 1973, he noted.

A spokesman for the Peoples Gas, Light & Coke Co. said there would be "complexities" in supplying a great increase in gas to Edison, mainly in accumulating large reserves supplies and in constructing the necessary tanks and pipelines.

Ward C. McCallister, president of Peoples Gas, told The Sun-Times his firm had tripled its sales of gas to Edison in the last year.

Stanley, the Air Pollution Control director, said Edison's equipment meets the demands of the city's pollution ordinance.

Asked whether he agrees with Illinois Atty. Gen. William J. Scott, who said air pollution has reached a "crisis," Stanley replied:

"That depends on how you define it. There are all kinds of air pollution problems and you have to devise special programs for each kind. Whether it's dangerous to you is up to a medic to say, not me."

8 UTILITIES FACE POLLUTION PROBE

By Donald M. Schwartz and Burnell Heinecke

The Illinois Commerce Commission on Wednesday ordered eight utilities to appear on Dec. 15 at an investigation into alleviating air pollution.

The firms ordered to appear are Commonwealth Edison Co.; Peoples Gas, Light & Coke Co.; Northern Illinois Gas Co.; Iowa-Illinois Gas and Electric Co.; Central Illinois Light Co.; Central Illinois Public Service Co.; Illinois Power Co., and Union Electric Co.

David H. Armstrong, commission chairman, acted on prodding from Gov. Ogilvie in the wake of six days of heavy air pollution in the Chicago area. Armstrong said in a press release:

"It is not the purpose of this proceeding to duplicate the enforcement of other agencies but rather to ensure that Illinois utilities are making the best possible use of available technology to produce needed energy at the minimal adverse effect on our environment."

Ducks Chicago question

Armstrong repeatedly turned aside questions at a press conference about the control of air pollution by the City of Chicago, saying the commission regulates utilities only.

But he did say that the commission has considerable power to require coal burning utilities, to install pollution control devices.

"We have broad powers," said Armstrong, "but as a practical matter I couldn't issue an order to shut Commonwealth Edison down and let the city go black."

Armstrong said further that his order tells People's Gas and Northern Illinois Gas Co. to give information at the hearing on the availability of natural gas.

The press conference was held in the State of Illinois Building, 160 N. LaSalle.

Earlier, Ogilvie had commented on air pollution in Chicago.

"It is clear from this episode that much too little was done too late," the governor said in Springfield as the persistent polluted haze was finally swept from Chicago skies by cool air from Canada.

The governor ordered Armstrong to obtain reports from major utility air polluters on their entire pollution abatement programs and on emergency plans for high pollution periods.

Ogilvie supported the order with the observation that the commission has legal power "to require every public utility to maintain and operate its plant in such manner as to safeguard . . . the public and . . . to require the performance of any other act which the health and safety . . . of the public may demand."

At the same time, the governor initiated a review which will include whether Chicago's exemption from state superivsion should be continued in the area of air pollution control.

3-area review

He directed Franklin D. Yoder, public health director, and Clarence Klassen, technical secretary of the Illinois Air Pollution Control Board, to examine three areas:

(1) State and city emergency anti-pollution plans and the means for making them more effective.

(2) The advisability of continuing to grant a state certificate of exemption to Chicago for control of air pollution.

Chicago has been permitted by the state to run its own show in air pollution control because it has its own pollution control department—just as the Sanitary District, until this year, was free of control by the state.

The district this year, however, was brought under the jurisdiction of the Illinois Sanitary Water Board.

(3) The City of Chicago's response to the just ended heavy air pollution.

In the meantime, lawyers in the State of Illinois Building, 160 N. LaSalle, wrangled over a Commonwealth

Edison Co. request for a 6.1 per cent rate increase while outside, pickets protested the utility's contribution to the air pollution burden.

At a brief hearing in the rate case, it was decided to postpone cross-examination of seven company witnesses, which was to have begun Wednesday, until Commonwealth Edison and opposing lawyers agree on cross-examination procedures.

CLEAN-AIR EDICTS OFFERED IN COUNCIL; DIMOUT SUGGESTED

By Harry Golden, Jr.

Two anti-administration aldermen proposed tough new measures to deal with air polluters, specifically the Commonwealth Edison Co., Monday in City Council.

Almost immediately Commonwealth Edison rejected the proposals, saying that the course of action it is taking to reduce air pollution is better.

The proposals came in the form of four resolutions, one by Ald. Jack I. Sperling (50th) and three by Ald. William S. Singer (44th).

Start to shout

All were referred to the Council's Health Committee. An administration-backed ordinance which would sharply increase fines for air pollution received support in the Council, but a vote was put off until the next Council meeting after a shouting match broke out on the floor.

Sperling's and Singer's resolutions were drafted separately, but all were aimed at combating conditions that led to the recent wave of air pollution in Chicago.

Sperling's resolution would direct the mayor, during times of air pollution alerts, to "call on industry, business and the general public to reduce their use of electricity to the lowest possible minimum" and to declare "power dimouts" until the pollution level was reduced.

Like war measure

Simultaneously, the mayor would urge suburban officials to join in the dimouts. Similar program to cut

down on consumer use of power were instituted during World War II.

Singer's resolutions are aimed at changing the city's current air pollution control ordinance, which would force companies to use coal with 2.5 per cent sulphur content or less beginning next July 5. The law calls for a gradual reduction to a 1.5 per cent maximum by the end of 1974.

Sperling had said that "the primary source of sulphur dioxide in Chicago and suburbs is the 9,000,000 tons of coal of high sulphur content consumed by Chicago industry and particularly by the Commonwealth Edison Co., which burns 6,000,000 tons of high sulphur coal, two-thirds of the total amount."

Proposals outlined

Singer's proposals call for:

(1) Scrap the gradual reduction plan for high-sulphur content coal, and replace it with an amendment demanding use of coal with 1.5 per cent sulphur content or below by next July. The amendment would apply to all fuel users in Chicago, and within a mile outside the city.

(2) Abandon a provision which allows a company to continue burning high-sulphur coal in some plants if it reduces usage of the coal at other plants. This is aimed at Commonwealth Edison's plan to burn gas and use nuclear power at some plants. Singer said that "sulphur dioxide emissions must be reduced at every plant every day."

(3) Insist upon the latest anti-pollution precipitators at plants "to insure the removal of 90 percent or more of particulate matter." Singer said that Commonwealth Edison's precipitators now work at about 97 per cent efficiency, and that the company still emits some 17,000 tons of particulate matter annually.

Singer also called for public hearings to determine why Commonwealth Edison says not enough low-sulphur coal is available. He said that "billions of tons of coal in Virginia and West Virigina contain less than 1 per cent sulphur."

At a press conference called while the Council meeting was still in progress, two Commonwealth Edison officials rejected the Sperling and Singer proposals.

Nuclear program

Saying that the resolutions are not "squarely addressed to the city's problem," James O'Connor, assistant vice-president, and Wallace Behnke, vice-president, outlined the company's plans for reducing pollution.

O'Connor said the company is reducing the amount of coal burned in Chicago generating stations by retiring older generating units in Chicago, by burning increased amounts of natural gas, and by proceeding with a $900,000,000 nuclear power program.

He said the nuclear generating units will enable the company to ultimately reduce the coal burned in Chicago by more than 50 per cent.

O'Connor said that existing furnaces cannot burn low-sulphur coal, and the company could not burn the coal by next July.

"It would take several years to modify these plants for a fuel which is not available in the amounts required," he said.

To ask exemption

Behnke confirmed that Commonwealth Edison will ask the city for an exemption from reducing the sulphur content in its coal next July. He said the company would base the request on its plans to phase out the use of all coal.

O'Connor denied that the company is Chicago's major air polluter. He contended that "even with a complete shut-down of Edison's six Chicago area plants, 98 per cent of the air contamination would remain."

At the City Council meeting, a vote on the administration proposal to stiffen fines against air polluters was deferred until the next meeting when Aldermen Leon M. Despres (5th), Claude W. B. Holman (4th), Seymour Simon (40th) and Singer began to argue the merits of the city's current plans to combat pollution.

"The mayor of Chicago has the best program in the nation," Holman said, and Despres and Singer rose to argue. Aldermen Fred B. Roti (1st) and Vito Marzullo (25th) then moved to table the motion.

Mayor Daley, obviously displeased with the vocal antics in the presence of several groups of visiting school children, said "That was a great demonstration before these fine children."

MIKVA BILL WOULD MAKE AIR POLLUTION A FEDERAL OFFENSE

Sun-Times Bureau

WASHINGTON — Rep. Abner J. Mikva (D-Ill.) Wednesday introduced in the House a bill that would make air pollution a federal offense and set federal standards on pollution sources.

The bill, titled the Air Pollution Abatement Act of 1970, was cosponsored by 19 other congressmen, including Rep. Frank Annunzio (D-Ill.). It was sent to the House Interstate and Foreign Commerce Committee.

The bill calls for additional rules and private remedies for air pollution abatement, and would give citizens the right to sue in state or federal courts.

Fines up to $2,000 a day

Penalties of up to $2,000 a day are provided for polluters, and the secretary of Health, Education and Welfare would be authorized to set special standards where climatic conditions make air pollution especially dangerous to health.

The provisions would take effect when an "inversion" developed, as it did in the Chicago area earlier this month. An inversion is the trapping of pollutants by layers of air of different temperatures.

In such situations, the secretary would have emergency powers to shut down for up to 72 hours industries that contribute to air pollution. The offender would be required to continue paying wages during the emergency.

Mikva said the bill would make enforcement of stringent national air pollution standards the policy and practice of the United States.

Chicago's air unsafe

"If our cities are to be saved, they have to have breathable air for the people who live there," he said. He noted that preliminary results of a government study indicated that a large percentage of Chicago's population is breathing air polluted over twice the "safe level" established by medical authorities.

"Citizens of this nation know that our environment will continue to deteriorate as long as Congress coddles the polluters of the very air we breathe," he added.

The bill also calls for an enforcement of state and local standards by the federal government or injured citizens when local authorities fail to act.

Pollution fight

Edison tells coal doubts

By Jay McMullen

An official of Commonwealth Edison Co. said Monday he is pessimistic about the company's ability to burn large quantities of low-sulphur coal.

Nevertheless, said Byron Lee, assistant to the president, Edison will try to burn 300,000 tons of low-sulphur coal next year compared with the 30,000 tons it burned in the last five months.

The company burns 6,000,000 tons of coal a year, most of it high-sulphur. High-sulphur coal creates a higher quantity of dioxide, a major air pollutant.

THE CITY Council has ordered industry to reduce the sulphur content of its coal to 2.3 per cent by July 1, 1970, and 1.5 per cent by 1974. Edison, which mainly burns coal of about 3.5-per cent sulphur, has said it will not be able to meet the council's deadlines.

Lee said at a press conference that Edison's tests of low-sulphur coal, which ranged in sulphur content from 1 to 1.5 per cent, turned up these defects:

- The coal created twice as much air-polluting particulate matter as high-sulphur coal.
- It cost twice as much as high-sulphur coal to produce an equal amount of heat.
- Slag runoff caused a rock-hard residue that had to be chipped off a boiler with a jackhammer.
- It is difficult to get it mined and shipped to Chicago "on a regular and dependable basis."

LEE SAID Edison's low-sulphur coal came from Wyoming and Montana, and not from Virginia and West Virginia where billions of tons of low-sulphur coal are said to exist.

He said the Eastern coal causes high amounts of slag that clogs up boilers, cannot be ground in Edison's coal grinders and causes even more particulate matter than Western coal.

Lee added that it would cost Edison $15,000,000 to $20,000,000 to shift entirely to low-sulphur coal.

He said the company will use only 4,000,000 tons of high-sulphur coal next year and will drop to 2,000,000 to 2,500,000 tons by 1974.

'Black Diamond' Boom: Kleenburn Coal Mines Enjoy Demand Surge

• • •

Air-Pollution Worries Spark Orders for Low-Sulphur Fuel Mined in Big Horn Mountains

By a WALL STREET JOURNAL Staff Reporter

KLEENBURN, Wyo.—This tiny, north central Wyoming town, named for the clean-burning coal mined here, is suddenly enjoying a boom, thanks to growing public concern over air pollution.

Coal has been mined in this section of the historic Big Horn Mountains since the days when Buffalo Bill Cody operated the nearby Sheridan Inn. But until recently its low sulphur content didn't seem to attract much demand for Kleenburn's "black diamonds."

Now, however, large orders for the coal from such distant utilities as Chicago's Commonwealth Edison Co. and Kansas City Power & Light Co. have forced Big Horn Mining Co., into double work turns. Big Horn Mining is a subsidiary of Peter Kiewit Sons' Co., an Omaha-based construction concern.

Instead of being shipped a few carloads at a time, Kleenburn coal is being loaded into unit trains of 60 to 65 cars each, reports the Chicago, Burlington & Quincy Railroad, which serves the area. The Burlington says it has had six unit trains in operation since Dec. 10 and plans 34 more. The road currently runs three loaded trains each week to handle the mine's output.

To further enhance the sudden appeal of Kleenburn coal, the Burlington says it cut the shipping rates to Kansas City to $8.26 a ton from $8.60 and to Havana, Ill., to $8.43 a ton from $11.30. From Havana the coal is barged to Chicago.

DEFENDANT'S EXHIBIT 160

WALL STREET JOURNAL
Page 1
March 19, 1970

Business Bulletin

A Special Background Report On Trends in Industry and Finance

POLLUTION CRACKDOWNS convince companies to close some facilities.

They find it more economical than trying to equip marginal plants with costly antipollution controls required by many governmental units. Giant Portland Cement Co. phases out a 65-year-old plant at Egypt, Pa., rather than spend $1 million to comply with Pennsylvania's air pollution control law. Jones & Laughlin Steel Corp. will close parts of its Pittsburgh iron foundry for similar reasons. Ohio Edison Co. decides to phase out four, occasionally used, coal-fired generating units in Toronto, Ohio, when restrictions tighten, rather than install new controls.

The pace of closings is expected to increase as enforcement agencies step up activities. "We'll lose one-third of the 1,000 gray iron foundries" when air pollution codes are in effect across the country, says a spokesman for the Gray and Ductile Iron Founders Society in Cleveland.

The Texas Air Control Board claims it was influential in getting two lumber companies, a feed supplement plant and a lime plant to close last year.

AREA CODE 312 - TELEPHONE FINANCIAL 6-7447

OFFICE OF
THE PRESIDENT

THE NEWS THAT NOBODY PRINTS

Dear Sir:

The sulfur dioxide level in the Chicago area has declined steadily over the last six years. The attached chart illustrates this improvement. In 1968 and 1969 the level was well below the suggested goal of less than .040 parts per million as published in the U. S. Department of Health, Education and Welfare Criteria.

This improvement in the ambient air is due entirely to the voluntary efforts made by Chicago citizens, since the sulfur restrictions of the Chicago Air Quality ordinance do not become effective until July 5, 1970.

The 1969 average sulfur dioxide level of .026 parts per million was reached five years ahead of the schedule projected by the coal industry when the ordinance was being considered.

Enforcement of the Chicago ordinance will prohibit 86% of Illinois coal from being sold or consumed within the city.

Very truly yours,

Otis J. Gibson

New Ruckus on Foreign-Oil Imports to Pin Nixon Between Pollution Issue, Coal Groups

By Burt Schorr
Staff Reporter of The Wall Street Journal

WASHINGTON — Last month, President Nixon sidestepped a possible collision with the oil industry over a Cabinet task force proposal to replace existing oil-import quotas with a system of tariffs. He adroitly delayed final action, possibly until after Election Day.

A new foreign-oil ruckus is heading Mr. Nixon's way, this time involving the coal industry, and it's doubtful the President will be so lucky in finding a safe neutral corner.

The conflict—currently working its way toward the White House through the Oil Import Appeals Board deep in the Interior Department—grows out of a request by Commonwealth Edison Co. to import foreign residual oil to fuel its Ridgeland generating station just outside Chicago's city limits. When Mr. Nixon approaches this question, however, he'll find his Administration uncomfortably pinned between two larger and politically more troublesome issues.

Air Pollution Rhetoric

On one side is the credibility of Nixon Administration rhetoric about wanting to clean up the environment. Commonwealth, to meet a 1970 commitment to help improve the quality of the air Chicagoans breathe, wants to substitute low-sulphur-content imported oil for the high-sulphur-content domestic coal currently being burned at Ridgeland. Thus a rejection of the utility's import application could be interpreted as meaning the Nixon Administration really doesn't care much about clean air. Deferring final action—as was done on the task force proposal—could lead to much the same interpretation and hurt Republicans in the fall election.

On the other side are the coal industry and the fact that existing oil-import regulations dating back to 1959 have permitted only a relative trickle of foreign residual oil (the molasses-like end-product of some refinery processes) into the important 19-state midcontinent region known as District II, which includes Chicago.

Coal representatives argue that once this barrier is breached, many other District II coal burners with air-pollution problems will flock to Washington to obtain foreign oil rights for their plants—the substantially higher cost of oil notwithstanding. This would mean a serious setback for coal demand in the 19 states, which currently account for more than half of total yearly U.S. coal use. As a result, the coal argument runs, promising techniques for removing most of the sulphur from stack emissions of coal-fired plants will languish for lack of interest, and investors will be leery of risking their money in development of new coal mines.

Coal-Industry Opposition

A number of Capitol Hill heavyweights from coal states, whose views can't easily be ignored by the White House, already have been mobilized behind these arguments by the National Coal Policy Conference and the National Coal Association, two major industry lobby groups. Together with the United Mine Workers union, they represent the chief formal opposition to the Commonwealth Edison application.

Rep. Edwards (D., Okla.), chairman of the House Mines and Mining subcommittee, for example, wrote the Oil Import Appeals Board that "the precedent-shattering nature of Commonwealth's application, if approved, will have seriously harmful effects upon our country's economic posture and national security. Apparently, Commonwealth has not concerned itself with the far-reaching effects approval of their application would have on similarly situated industries. . . . It is difficult for us to see how the many, many additional applications which would inevitably follow could be treated differently."

For the oil import board, at least, such appeals don't seem to have had much effect. The panel's chairman, Lewis Flagg III, an Interior Department employe, hasn't released the Commonwealth ruling. The board's other two members, Stanley Heginbotham, Deputy Assistant Commerce Secretary for Resources, and Paul H. Riley, Deputy Assistant Defense Secretary for Supply, who constitute the necessary majority, have signed a finding that the utility is faced with "exceptional hardship" and should get 4.5 million barrels of imported residual oil in the 12 months starting April 1.

Opinion Dismisses Objections

The majority opinion dismisses coal-industry objections and seems to open the door wide to other foreign-oil applicants. The opinion states that the "basic issue . . . is not one of coal versus oil since the petitioner has made a decision to discontinue burning coal as a basic fuel at the Ridgeland station under any circumstances." The opinion notes that Commonwealth did get a belated offer of domestic residual oil from Standard Oil Co. (Indiana), but this fuel would contain 70% more sulphur than the foreign oil and cost a third more.

A formal appeals board decision, however, will represent only a first step through the oil import labyrinth for Commonwealth. Next, it's up to Interior Secretary Hickel to fit the ceiling on residual oil imports into District II, currently set at a more 210,000 barrels yearly. Presumably such action first would have to clear the President's new interagency committee on oil import policy and perhaps the White House itself. Routine issuance of an import license by the Oil Import Administration would follow.

New Ruckus on Foreign-Oil Imports to Pine Nixon Between Pollution Issue, Coal Groups (Continued)

Interior Department officials insist, though, that this emergency relief procedure, provided under the original Eisenhower oil-import proclamation, is the proper way to handle the backing of additional residual-oil applications building up rapidly in the appeals board office. So far, District II import license requests totaling more than 26 million barrels (equivalent to about six million tons of coal) are on file.

Extent of Demand Unclear

Just the other day, for example, Detroit Edison Co. asked for 8.6 million barrels in the 12 months beginning April 1 to provide back-up fuel for its Delray station. The plant normally burns pollution-free natural gas, but increasingly tight supplies of that energy source have increased the periods when its gas is diverted to home use. More critical, the utility says, is the fact that domestic refiners from which it formerly purchased residual oil aren't any longer offering to supply it.

There are strong indications, moreover, that the full extent of demand for foreign residual oil in the 18-state region has only begun to reveal itself. One District II case presently before the Oil Import Appeals Board involves a group of 12 oil-terminal operating companies, which hasn't specified how much residual oil its members would like to bring in. Elmer L. Hoehn, a member of the law firm representing the terminal operators (and formerly oil import administrator in the Johnson Administration) says his clients are still canvassing their customers' needs. Preliminary findings suggest that dozens of new local air ordinances will require "tens of millions" of barrels of foreign residual oil to satisfy them, Mr. Hoehn comments.

For the long term, it's obvious that the Administration must at least consider a broad policy change designed to make heavy industrial fuel oil as easy to obtain in District II and other districts as it is currently in the 10 eastern seaboard states comprising District I.

Oil Imports in Other Areas

In prior years, when the environment wasn't a major issue, residual oil use hinged largely on its transportation costs. Because it had easy tanker access to Venezuelan refineries, therefore, District I started out under the import program with an "historic" right to import vastly more fuel oil than all the other districts combined. In 1968, controls on foreign residual oil into District I were loosened to the point that, in effect, importers could bring in all they were able to sell.

The recent report of the Cabinet task force on oil-import control indicates broad support already exists within the Administration for opening the entire country to foreign fuel oil. The panel majority, representing five of its seven members, questioned the rationale of allowing imported heavy oil access to one region but not others. It said this inequity would be ended in the overall change to a tariff system. The minority members, Commerce Secretary Stans and Interior Secretary Hickel, also suggested that "consideration should be given to applying (District I) policy uniformly across the U.S.," even though the two dissenters would retain other features of the present quota system.

Most Venezuelan and U.S. crude oils actually leave the ground with sulphur levels close to those in coal, and the troublesome mineral eventually ends up in the residual product. However, there are well-established commercial processes for desulphurizing oil—an advantage coal still lacks. A number of companies currently are working on ways to remove sulphur dioxide, the gas produced when high-sulphur-content coal is burned, but many experts in the field believe it will be at least several years before all of the wrinkles are out of these techniques.

Meantime, frustrated coal executives have watched residual oil use mushroom in District I at the expense of their product. "In the 1966-67 period, after controls were dropped, 37 utilities from New England to Washington decreased their use of coal by 20% while increasing their consumption of oil by 84%," the National Coal Association told the Oil Import Appeals Board. "Almost without exception," the association said, oil also has been the fuel chosen for new East Coast fossil fuel plants. As a result, it said, coal "barely held its own" in District I between 1966 and 1968; in the first nine months of last year, its use actually declined, while oil use continued to grow.

Commonwealth Edison Is Allowed to Import Low-Sulphur Fuel Oil

Hickel Says One-Year License Doesn't Establish New Policy; Coal Industry Fought Action

By a WALL STREET JOURNAL Staff Reporter

WASHINGTON — Interior Secretary Hickel granted Commonwealth Edison Co. the right to import 4.5 million gallons of low-sulphur residual fuel oil for its Ridgeland power station near Chicago.

The import license, effective for the year beginning April 1, had been opposed vigorously by the coal industry, chiefly on the grounds that foreign residual oil previously hasn't been licensed for use in Midwestern or Southern states and that its admission at this time would sharply cut coal sales. The conflict had placed the Nixon Administration in a squeeze between influential coal-state lawmakers on Capitol Hill and a desire to maintain its clean-environment reputation.

Demand for low-sulphur foreign residual oil is building in many localities because of new air pollution control ordinances. Because of technological changes, U.S. refiners currently have little residual oil to sell. Coal is a substantially cheaper fuel, but commercially acceptable methods for removing sulphur from coal fire stack emissions still are only under development.

Secretary Hickel said he is granting Commonwealth Edison's request "in the interest of curbing air pollution in the Chicago region." He emphasized, though, that his decision is based "on a very special set of circumstances and does not represent establishment of a new general import policy for low-sulphur residual fuel oil." A test of such policy is likely to occur in the near future as the Interior Department handles a number of requests similar to Commonwealth's.

U.S. NEWS & WORLD REPORT

DEFENDANT'S EXHIBIT 164

THE REAL MEANING OF ALASKAN OIL FINDS

Benefits for all the U. S. are to flow from Arctic oil fields in the 49th State.

Potential output would double the nation's proved reserves. Enough oil to meet all demands is assured even if U. S. were cut off from other sources.

Huge pipeline is to carry oil down through Alaska for shipment to the West Coast, bringing initial benefits to that region.

Reported from
NEW YORK AND WASHINGTON

The full meaning of recent oil strikes in northern Alaska is suddenly becoming clear to industry experts and Government officials.

The essential fact is that Alaskan finds will make the U.S. self-sufficient in reasonably priced oil for the foreseeable future.

Almost overnight the U.S. appears to have doubled its petroleum reserves.

Vast new pool. The center of world oil exploration will now move to the Arctic—U.S., Canadian and Russian—says Walter J. Levy, a top international oil consultant.

Source of all this interest is a pair of wells on land near the Arctic Ocean's Prudhoe Bay. Atlantic Richfield Company and a subsidiary of Standard Oil Company (New Jersey) drilled them last year. Result: DeGolyer & MacNaughton, a Dallas oil-consulting firm that announced the strikes, estimated a pool holding 5 to 10 billion barrels of oil had been hit.

Oil companies have been racing for drilling rights on what's called Alaska's North Slope ever since. But only now are the experts putting together a clear picture of what the Prudhoe Bay discoveries mean. And that picture is bright.

Alaska may be the biggest and most important oil discovery since Middle Eastern fields were found.

Outlook: Independence. Before Prudhoe Bay, the U.S. faced the prospect of having to import 30 per cent of its oil needs by 1980. Either that, or the price of oil would have had to be artificially pegged here at around $4.20 a barrel, compared with about $3 today, in order to boost production from high-cost wells, oil shale and coal.

Now, however, the U.S. will be able to hold prices at present levels, or possibly even let them drop somewhat. The Government generally keeps oil prices at home about double the price of oil in the world market by restricting imports. Imports are set at 12.2 per cent of demand.

Americans, with Alaskan oil coming in, will not have to rely on production in Arab-ruled lands of the Mideast, in Venezuela or even in Canada for gasoline, heating oil and other products made from petroleum.

Counting the riches. How much oil is there in Alaska? No one knows the answer yet. The estimate of 5 to 10 billion barrels for the Prudhoe Bay field is for just one geological "structure." And there are an estimated 10 to 20 similar structures in the North Slope region alone.

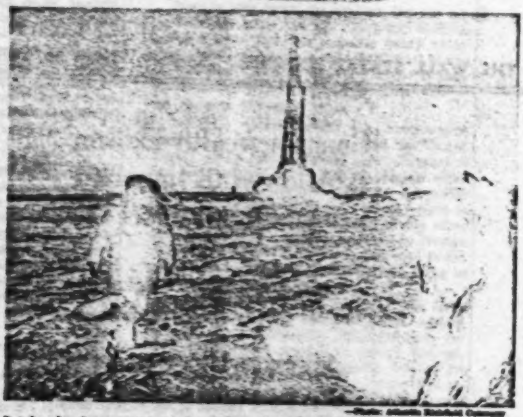
Even oil men with reputations for conservative estimates are projecting 40 billion barrels for the North Slope if present soundings continue to prove out. You see how much oil that is by comparing it with total reserves for the rest of the U.S.—only 32.5 billion barrels, according to "The Oil and Gas Journal," trade magazine for the industry.

And that isn't all. Alaska also has nine other geological areas like the North Slope—"sedimentary basins"—where oil might be found. It is no wonder that Mr. Levy says every large U.S. oil firm will have an "absolutely compulsive need" to hunt for oil in the Arctic once the large size of the resources is established.

For domestic use. Where will all this oil be sold? Only in the U.S., say the experts. Europe, Japan, other oil-hungry regions will not get any.

Reason for this is simple economics. Oil sold in the U.S. brings $3 a barrel, compared with about $1.50 abroad. The only thing that would change this pattern would be discovery that the Alaskan oil is so cheap to produce it could compete against Midwestern crude oil. And that isn't considered likely.

Pipeline-construction plans just unveiled by three companies with the big-



—Photo: Atlantic Richfield Company

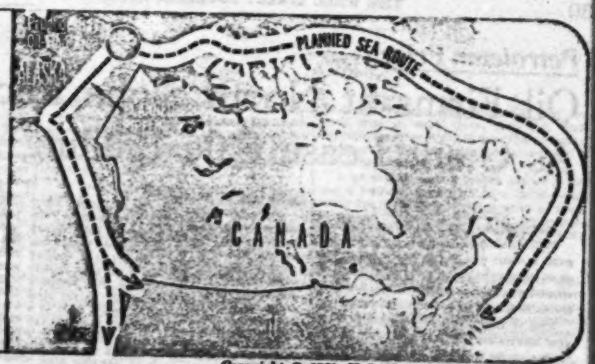
It takes hardly more to tend the drilling rigs in Alaska. The recent discovery of a vast new field near the Arctic Ocean may have doubled U. S. petroleum reserves.

TAPPING ALASKA'S OIL WEALTH —

Vast oil discoveries at Prudhoe Bay, on Alaska's North Slope, can help keep the U. S. self-sufficient in oil — if transportation can be arranged at reasonable cost. Map shows two plans now in the works:

1. A pipeline across Alaska to the Cook Inlet area, where ships would pick up oil for West Coast ports.

2. An all-tanker route from Prudhoe Bay to the East Coast of U. S. via a Northwest Passage through islands north of Canada's mainland.



Copyright © 1969, U. S. News & World Report, Inc.

gest stakes in Prudhoe Bay—Atlantic Richfield, Jersey Standard and British Petroleum Company—show what is to happen.

Prudhoe Bay oil is to be piped to Alaska's southern coast, shipped to Puget Sound and other Pacific Coast points for processing and sale there. Atlantic Richfield already is planning to build a 100,000-barrel-a-day refinery near Bellingham, Wash., to process Alaskan oil. Other refineries may be built in Alaska.

The pipeline is to be one of the world's biggest—48 inches in diameter and 800 miles long. Initial capacity is to be 500,000 barrels a day, just about the amount of oil the West Coast is thought to need for self-sufficiency.

Ultimate capacity for the trans-Alaskan line is said to be 1.5 million-plus barrels a day. This indicates to oil-industry men that within a relatively few years a new pipeline probably will be built connecting the Seattle area with Midwestern industrial centers as far east as Chicago.

Trouble for Canada. Left out, as U. S. analysts now see the future, is Canada's oil industry—unless Canadian Arctic oil can be developed and transported cheaply enough to find a big market in Europe. The price problem makes this doubtful, in the opinion of some experts.

Canadians are currently exploring for oil in their own Arctic islands and near the mouth of the Mackenzie River, not far across the border from Alaska.

A number of other Canadian oil finds are shut in—nonproducing—because of lack of transportation or lack of markets.

Oil men in Canada have been pushing for a pipeline running from Prudhoe Bay diagonally across Canada to Chicago. Their proposal would have given U. S. companies free transit in return for letting Canadian producers use the line for sending their crude petroleum to market in the U. S.

Now it appears that such a pipeline is a long way off.

In fact, say the experts, even Canada's present exports to the U. S. may be in trouble. Canada currently sells about 500,000 barrels of oil a day to the U. S. at the American price of $3 a barrel and imports some 600,000 barrels a day at the world price of around $1.50 a barrel. Thus, it is argued, the U. S. consumer subsidizes Canadian companies.

Floods of Alaskan oil also are likely to increase demands from owners of high-cost wells in older producing States for lower oil imports from Canada and elsewhere. That promises headaches for President Nixon: How to keep oil men in the U. S. and governments in Canada and Venezuela happy.

Officials in Washington believe the outcome will be stepped-up consideration of a U. S.-Canadian continental oil policy. This presumably would mean free access for Canadian oil to lucrative U. S. markets. But it probably would also mean a requirement that Canada agree to limit imports of cheap foreign oil, it is reported in Washington.

Boost for shipbuilders. Analysts are discovering, too, that the benefits of Alaskan oil seem sure to spread well beyond the oil industry. To the shipbuilding industry, for one.

New tankers will have to be built to carry the large amounts of oil coming out of the Alaskan pipeline to refineries in the "lower 48" States. Federal law requires that all trade between U. S. ports be carried in American-made and manned ships.

No orders have been announced yet, but industry sources understand several 200,000-ton tankers are soon to be built, the largest ever made in the U. S. A possible step in that direction is a new project by Bethlehem Steel Company's Sparrows Point shipyard to construct facilities for 200,000-ton ships.

In San Francisco, Bethlehem also is building big new dry docks capable of holding a supertanker for repair.

Northwest Passage? Alaskan oil could finally accomplish what Henry Hudson and other explorers couldn't—the opening of the fabled Northwest Passage.

A Jersey Standard tanker, the *Manhattan*, is being fitted with a new type of ice-breaking prow for a try this spring at sailing from the Atlantic Coast, across the top of Canada to Prudhoe Bay.

The bow, named the "MIT bow" after the Massachusetts Institute of Technology where it was developed in co-operation with the U. S. Coast Guard, lifts the ship onto the ice, where sheer weight causes it to break through. This leaves a channel behind the lead ship for a train of smaller tankers to follow.

The Canadians are experimenting with still another type of icebreaker, the "Alexbow," named after inventor Scott Alexander. It splits the ice from below and throws it aside.

If the new icebreakers work, they would open the heavily populated Northeastern U. S. to supplies of Alaskan oil. But don't look for a completion of the Northwest Passage all the way into the Pacific Ocean soon, say the experts. Thickness of ice around the northwestern tip of Alaska runs 50 feet or more, far too much for today's icebreakers to tackle.

If ice does block the tankers, it will be one of the few hitches in Alaskan oil's remaking of the industrial and transportation map of North America.

Petroleum Prize

Oil Firms at North Slope Race for Data As Giant Lease Sale Bidding Approaches

By Robin W. Winsley
Staff Reporter of The Wall Street Journal

PRUDHOE BAY, Alaska — A giant poker game is under way on this frozen Arctic desert as oil companies prepare for what many veteran editors are betting will be the first $1 billion lease sale in the industry's history.

They're racing in tightest secrecy to gain vital information they'll need to bid in mid-September on up to 700,000 acres of state leases on Alaska's North Slope and under the Arctic Ocean near what's likely to prove the biggest oil field in North America.

To probe for those data through 1,500-foot deep permafrost (a mixture of permanently frozen ice, sand and gravel), 14 oil companies have assembled 28 towering drilling rigs on the Slope, with at least three more on the way. To support their frantic drilling activity, they've already moved, mainly by air, more than 50 million pounds of equipment and supplies into this area, about 1,200 miles from the North Pole. And they've built an amazing complex of ice fields, base camps, supply dumps and all-weather roads atop bordering five-foot-deep layers of gravel over about a 100-mile expanse of barren plain.

Those companies and unannointed others who don't have rigs or acreage on the Slope have dozens of "oil scouts" shuttling for clues as to what the others are finding. Some companies have purged armed guards at their drill sites, and at least two have cleared out all contractor personnel before making well tests. Reports are sent by courier, and radio references to wells are coded. Big crews even try to shield their operations from scouts in planes and helicopters.

Wrinkles at the Airport

With security as tight on the Slope, many scouts are posted 300 miles to the south in Fairbanks, where they watch supplies being loaded aboard long fleets of cargo planes around-the-clock at the Fairbanks airport, and observe airline customers and hotels to see what personnel are heading for the Slope. If a company ships a certain size of "casing" (heavy steel pipe used to seal off liquids from a hole) or a "Christmas tree", (the assembly of valves and fittings used to control oil or gas flow from a well), or a certain well services specialist arrives in town, it can be a valuable clue to what's happening at a rival's drillsite.

"All exploratory wells on the Slope right now are simply being plotted where they can best evaluate inbound acreage and provide as much information as possible for next fall's lease sale," Theodore F. Bradshaw, president of Atlantic Richfield Co., says in New York. "This means the tightest security, and we hope our security is as tight as anyone's," he adds.

It was a series of announcements last year by Atlantic Richfield that touched off the excitement here. They reported that an evaluation of data from two oil discovery wells on acreage held jointly by Atlantic Richfield and Humble Oil & Refining Co., chief domestic subsidiary of Standard Oil Co. (New Jersey) gives the "reasonable expectation" further drilling will prove up an oil field containing 5 billion to 10 billion barrels of crude oil.

Magnitude of Reserves

The latter figure would be more than one-fourth of known oil and gas liquids reserves in the rest of the U.S. and as much oil as Saudi Arabia has produced to date. It also would exceed the six-billion-barrel East Texas Field, currently North America's biggest, which nearly wrapped the industry with a flood of oil in the initial years after its discovery in 1930.

"Everything drilled by everybody on the Slope will be tight as a drum until September," says Harry Warman, Alaska operations manager for British Petroleum Co., the only other company to commit publicly it has made an oil discovery on the North Slope, and second only to Atlantic Richfield in total drilling activity here.

A green "Christmas tree" (the assembly of pipes and valves in the only kind of tree on the Slope) sits atop BP's Put River No. 1 well, but the company steadfastly declines to disclose any test data from the well, or to comment on reports it's testing another possible discovery at its Put River 33-11-13, five miles to the west.

Alan Cuthbertson, BP's 37-year-old drilling superintendent, who came to the frigid Arctic from steamy Abu Dhabi on the Persian Gulf, does concede, however, that "it's likely" Put River No. 1 found the same oil formation as did the Atlantic Richfield-Humble Prudhoe Bay No. 1, three miles to the north, and the Atlantic Richfield-Humble Sag River No. 1, three miles to the southeast.

Both tests released are Standard Oil Co. of California and Mobil Oil Corp. (operator for a joint venture with Phillips Petroleum Co.). The word all over the Slope is that each of the two has completed an oil discovery well, but both companies decline to confirm or deny the reports. Perhaps significantly, BP is drilling a well just 1,350 feet north of California-Mobil's rumored discovery, about six miles south of Put River No. 1, and is preparing another rig site just 1,350 feet northeast of the Humble well. There's also a rumor that Atlantic Richfield-Humble have a third discovery well six miles east of their Sag River well.

Pan American Petroleum Corp., exploration

and production subsidiary of Standard Oil Co. (Indiana), also has reported discovery of natural gas about 40 miles southeast of Prudhoe Bay, but both Pan American and other companies here decline to evaluate the significance of that find.

OIL FIRMS AT NORTH SLOPE RACE FOR DATA AS GIANT LEASE SALE BIDDING APPROACHES
(Continued)

More Valuable Than Money

Under Alaska law, oil companies can keep well data secret for up to 25 months. They must file reports with the state within a month of a well's completion, but this information can be kept confidential for up to two years. As an extra precaution, the state has locked the North Slope reports in a bank vault in Anchorage. Johns the Alaskan operations engineer for one major oil company, "I wish my talents included opening bank vaults—they could keep the money; I'd just like a peek at those reports."

The Securities and Exchange Commission has also clamped a lid on announcements about reserves and probable production from rules until more wells are drilling on the Slope. But high-level sources report the North Slope wells are "Middle East type" and are likely to produce at rates "of about 5,000 barrels a day."

One indication of the confidence of the oil companies in the amount and likely profitability of North Slope oil are joint plans to build a $900 million, 800-mile pipeline across Alaska to a warm-water port in the south. "This line will definitely be built, and we'll start as soon as we get needed clearances from the Federal Government," reports Atlantic Richfield's Mr. Bradshaw. A formal application to the Bureau of Land Management, which must clear the valuable rights over Federal land, is being prepared, he adds.

Mr. Bradshaw says the planned 48-inch diameter Trans-Alaska pipeline could carry up to 2 million barrels of oil daily with appropriate pumping stations and storage capacity. It will handle 500,000 to 700,000 barrels of daily output as scheduled completion in early 1972, but will be expanded as northern develop, he reports.

Atlantic Richfield estimates that California alone will have a 600,000-barrel-a-day crude oil deficit by early 1972, he adds. He asserts that other companies have asked to join Atlantic-Richfield, Humble and British Petroleum in building the common carrier line, but he declines to identify them.

"We expect to get this oil into West Coast markets by 1972," he reports, "and our calculations show that it will be able to compete very favorably with other domestic crudes." This will likely involve another $1 billion investment if a pipeline is used, regardless of whether it's a transcontinental line from the West Coast to existing systems in the eastern part of the country, or a line down Canada's MacKenzie River valley, he says. Ice-breaking tankers, another option, would be a lower-cost method of moving the oil to the East Coast, he adds.

Possible Sales in Escape

Humble Oil has eased the giant 115,000-ton tanker S.S. Manhattan into five parts and has three ships-its hauling up its hull with an ice-breaking bow, its hull and protection for the rudder and screws.

In June, the hulks, owned by Seatrain Lines Inc., will start for Prudhoe Bay to test the Northwest Passage through the Arctic Islands. If it's successful, ice breakings, ranging up to 250,000 tons and costing up to $40 million are likely to be built. "We'd like to get some North Slope oil directly into Western Europe, if ice-breaking tankers prove feasible," reports Michael L. Haider, chairman of Jersey Standard. To prepare for loading tankers at Prudhoe Bay, scientists of the University of Alaska are spraying water (which instantly freezes) on kept ice islands about 20 miles into the Arctic Ocean, hoping to add enough weight so they'll permanently ground on the ocean bottom to serve as mooring terminals.

Temperatures on the Slope last winter dropped to as low as 70 below zero and winds hit hurricane force of 100 miles an hour, pushing engines and equipment with such heat power that had to be shipped out by land. The sun stayed below the horizon for four months, causing a high turnover on the 12-hour day, seven-day-week, four-to-six-week work stints on the Slope.

By contrast, the sun will shine three straight months this summer, with temperatures reaching 100 degrees above, turning the Slope into vast lakes and rivers and stirring up clouds of mosquitoes.

"We expect North Slope oil to be more profitable than that from the Middle East, despite much higher production and transportation costs," asserts BP's Mr. Wertzen, a veteran of Middle East operations that have provided his company with about one-fifth of the Free World's known crude oil reserves.

North Slope production costs may range as high as $1 to $1.20 a barrel, compared with only 15 cents to 20 cents a barrel in the Middle East, he estimates. He notes, for example, that North Slope oil comes up at about 180 degrees Fahrenheit, and that some means will have to be found to cool it so that it won't melt the permafrost. Drillers report they've already having troubles with steel pipe and collapsed casing in the permafrost even when they use chilled "mud" (a chemical mixture) or air to cool the drilling bit.

BP reports its drilling costs are running $9 million for a well on the North Slope, and Atlantic Richfield says the "Beaufort No. 2" dry hole it drilled on its first bid on the Slope cost $4.5 million. Most companies expect most of wells to develop the Prudhoe Bay field will be much more modest. However, it's estimated that oil companies will have up to $300 million invested on the Slope by year-end—BP is spending about $6 million a month and says that may double by year-end.

Cost of transporting North Slope oil to the West Coast by pipeline and U.S.-flag tanker will likely be about $1.10 a barrel, indicating a wellhead price of about $1.80 a barrel for the medium-grade crude in the Prudhoe Bay field. That compares with about $1.60 to $1.80 for comparable Middle East grades, and Middle East governments take more than half the profit from oil output there, while U.S. crude production carries a 27½% depletion allowance on the gross that can eliminate taxes on up to half of net income.

A production rate of 600,000 barrels a day and a wellhead price of $1.80 a barrel would mean the North Slope would produce an annual income of about $400 million, or about $800 million in gross taken out of the Klondike in the entire history.

Resolution of Acreage

Oil companies have until June 25 to consolidate acreage they'd like to bid on next September. Peter Denton, chief of the mineral section of the state's division of Lands, says only those tracts "receiving the most significant interest" will go on the block.

But the sale is likely to be only the beginning. The state has claimed title to millions of acres south of Prudhoe Bay under the statehood act. Pending legislation in Congress would validate Native and Indian claims and end a freeze on transfer of Federal land to the state. Mr. Denton says the state then plans to offer this land for competitive bids. Then, he relates, will breathless noncompetitive claims that have been filed on the same land with the Federal Government, a move some disgruntled Alaskans plan to oppose.

The state bill would permit the Federal Government to open to bid the vast 23-million-acre Naval Petroleum Reserve No. 4, which borders the present exploration area on the [illegible] shores that had been sold earlier.

Despite the profit-taking yesterday, gains on the New York Stock Exchange managed to show a moderate lead over Tuesday's, with 716 issues up and 541 down of the close.

Big Board Volume Down

Volume on the Big Board slowed to 31,320,000 shares from 38,320,000 Wednesday, which was the highest since Dec. 29 and among the busiest sessions in the exchange's history.

Institutions, which accounted for a good part of Wednesday's activity, were less active yesterday. Trades of 10,000 shares or more, a measure of their dealings, totaled 76, down from the near-record level of 110 the previous day.

Jersey Standard Unit to Send Oil Tanker Through Northwest Passage in Test Run

By Jonn D. Williams
Staff Reporter of The Wall Street Journal

NEW YORK—In mid-July, as part of a $60 million gamble, a big oil tanker will start a voyage from Philadelphia via a polar route north of Canada to the North Slope of Alaska at Prudhoe Bay. And then it is to come back.

Humble Oil & Refining Co., at Houston, a subsidiary of Standard Oil Co. (New Jersey), is hoping the test will prove the feasibility of moving oil year-round from the new Alaskan fields to the East Coast of the U.S.

The SS Manhattan, specially fitted as an icebreaker, is scheduled to bull its way through the ice floes of the famous Northwest Passage on a 30-day roundtrip. T. J. Pinto, general manager of Humble's marine department, said if the experiment is successful, the company will honor it by October or, the earliest. If the results are negative, "we'll leave faster than that," he said. The odds are long, he conceded. For example, the Manhattan's twin propellers may fail in the ice.

But the payoff will be high if it works. Jack F. Bennett, general manager of Humble's supply department, estimated that moving the Alaskan oil by sea to the East Coast would be 40 cents a barrel cheaper than via a transcontinental pipeline.

Humble decided on the venture last December. In mid-January it contracted to charter the 115,000-ton Manhattan—the largest U.S.-flag tanker—from Seatrain Lines Inc. for two years at a total charge of about $10 million. Humble may renew the charter and has an option to buy the 940-foot-long vessel.

The past winter the Manhattan was sliced into four sections, three of which were towed to shipyards for modifications at Mobile, Ala., Newport News, Va., and Bath, Maine. A new bow with two-inch-thick steel plates has been built to help slice through the ice. Other sections have a special 1¼-inch-thick steel belt to ward off the pressure of ice on the vessel's sides.

The various modification tests will bring the ante to about $60 million.

The powerful 43,000-horsepower Manhattan is currently being outfitted at a Chester, Pa., shipyard and will be etched out early next month before starting the 4,500-mile voyage. This is half the distance it would take to go to Alaska via the Panama Canal. In any event, the Manhattan—now 1,005 long, or 65 feet longer than prior to her refitting—is too large for that canal's locks. And her new weight is 130,000 tons, 9,000 more than before.

If the gamble pays off, Humble plans to build six ice breaker tankers, each of 250,000-ton size, for a total cost of $900 million, Charles F. Jones, Humble's president, told a press conference here. This would be more than twice the cost if the tankers were built in Japan. U.S. law requires that vessels serving U.S. intercoastal ports be owned by U.S. labor and built in U.S. shipyards.

Mr. Jones speculates that if Humble's attempt proves itself other U.S. oil concerns would build up to 20 new tankers by 1980, enlarging the current U.S.-flag oil tanker capacity by 2½ times.

Humble officials made it clear how much of a gamble the project is. M. A. Wright, Humble's chairman, said that Atlantic Richfield Co. and BP Oil Co. have elected to take "a piece of the action at 25 million each," as they join the Northwest Passage experiment. Mr. Jones, the president, said, "We're willing for a seven on this cast (of the dice) and not for a point."

Alaskan oil production from the North Slope area is expected to begin in the early 1970s at a time when oil flow will begin to decline in the lower 48 states. By 1980, Humble officials predict, the total flow from the Alaskan area will be about two million barrels a day—equal to the current consumption in all of New England, New York and New Jersey.

Should the polar sea route test fail, Humble officials said they would consider pumping the oil across Canada and the U.S. via a new pipeline.

Humble, Atlantic Richfield and BP Oil have already decided to build an 800-mile, $900 million pipeline from the North Slope to the southern coast of Alaska. Pipe has been ordered for delivery starting in August; completion is slated for early 1972. Crude oil coming down via this line will be shipped to Hawaii and West Coast markets.

The Manhattan will carry two helicopters on her deck. These planes will fly ahead of the vessel to test ice conditions and help choose the most favorable route. Two U.S. Coast Guard vessels will accompany the Manhattan to lend assistance, if needed.

Three Oil Companies to Study Feasibility Of Building First Coast-to-Coast Pipeline

By a WALL STREET JOURNAL *Staff Reporter*

NEW YORK—Three major companies exploring for oil on Alaska's Arctic North Slope announced they'll make a feasibility study of building the nation's first coast-to-coast oil pipeline.

The study will consider construction of a large-diameter crude oil pipeline from the Puget Sound area of Washington to the Eastern Seaboard, by way of Chicago, they said. It would be about 2,600 miles long.

The project was announced jointly by Atlantic Richfield Co.; BP Oil Corp., U.S. operations subsidiary of British Petroleum Co.; and Humble Pipe Line Co., a subsidiary of Standard Oil Co., (New Jersey).

Likely cost wasn't disclosed. But in an interview earlier this year, Thornton F. Bradshaw, president of Atlantic Richfield, estimated such a line would probably cost over $1 billion.

The three companies are already planning to build a $900 million, 48-inch diameter crude oil pipeline from the North Slope to the warm water Alaskan port of Valdez. From there, oil would be shipped to the U.S. West Coast by tanker.

The U.S. transcontinental line is only one of three methods being considered for moving Alaskan oil to the eastern U.S. Humble is also planning next month to send an ice-breaking tanker from Philadelphia through the "Northwest Passage" to Alaska to test feasibility of that method of supplying the East Coast. And several companies are also studying the feasibility of a crude oil pipeline through Canada from the North Slope.

Northern Natural Gas Plans Major Canada Pipeline

Cost of System to Transport Canadian Gas to the U.S. Put at About $1.4 Billion

Government Approval Needed

By a WALL STREET JOURNAL Staff Reporter

OMAHA, Neb.—Northern Natural Gas Co. is going to build a major pipeline system in Canada at a cost of about $1.4 billion to transport Canadian gas to the U.S., W. A. Strauss, chairman and president, said.

The total cost, to be spread over a five-year period, will be met in part by "major" participations of Canadian companies, he added. The cost to Northern Natural wasn't disclosed. A spokesman said that required governmental approval for the project was being sought.

However, Mr. Strauss said that plans call for construction of two "large diameter" pipelines from the producing areas in Alberta and the Northwest Territories to Northern's distribution system in Minnesota. The distance from the Minnesota pipelines to the province of Alberta is about 600 miles and about 1,700 miles to the Northwest Territories.

To implement plans for participating in the development of Canadian natural gas, Mr. Strauss said, Northern Natural has acquired a majority stock interest in Consolidated Pipe Lines Co., Calgary, Alberta. Terms of the purchase, made from a group of investors, weren't disclosed.

"Organized in 1955, but existing at present only as a "paper" company, consolidated Pipe Lines has the right to construct and operate pipelines in Canada, subject to government approval.

In recent years, considerable oil and gas exploration activity has taken place in Canada's Northwest Territories with many major oil companies participating in the search for additional reserves.

Currently, Northern Natural Gas is adopting advance payments and other incentives to develop natural-gas reserves for export to the U.S., Mr. Strauss said. He added that "negotiations are currently in progress with a number of producers and we are optimistic that similar reserves will be dedicated within the next few weeks."

The current program represents Northern Natural's second effort to import Canadian gas. In 1960, the company sought Federal Power Commission approval of a plan to bring Canadian gas into the system. However, the Federal agency turned down that application in favor of a similar proposal made by Great Lakes Pipeline Co.

That decision was appealed to the courts and subsequently remanded to the FPC for further hearings, scheduled to be resumed June 10 before a commission examiner.

Northern Natural Gas operates in the Midwest with its principal distribution lines in Minnesota, Iowa and Wisconsin. Gas supplies are obtained from Southwest producing areas.

Peoples Gas Unit Plans To Buy Midwest Area's First Gas From Canada

WSJ, p. 2, 6/18/69

By a WALL STREET JOURNAL *Staff Reporter*

CHICAGO — Natural Gas Pipeline Co. of America, subsidiary of Peoples Gas Co., plans to purchase 155 million cubic feet of Canadian gas daily beginning Nov. 1, 1970, George P. Garver, Natural Gas Pipeline president, said.

If approved by the various regulatory agencies, the arrangement will mark the initial entrance of Canadian gas into the Midwest market. Heretofore the area has relied on domestic gas produced in the South and Southwest.

The gas will be purchased from Great Lakes Gas Transmission Co., which is supplied by Trans-Canada Pipe Lines Ltd., Toronto. Price of the gas wasn't disclosed.

To minimize Natural's capital investment, the company has arranged to deliver the additional gas to the Chicago area by using facilities of Michigan Wisconsin Pipe Line Co. Michigan Wisconsin will accept deliveries of gas from Great Lakes Transmission and then, in turn, make an equal amount of gas available in Chicago to Natural Gas Pipeline.

Alberta Agency Backs Northern Natural On Bid to Export Gas to U.S. Midwest

By a WALL STREET JOURNAL Staff Reporter

CALGARY—The Alberta Oil and Gas Conservation Board has decided to allow Northern Natural Gas Co. of Omaha to export 1.886 trillion cubic feet of natural gas from the province to the U.S.

The decision, subject to approval by Alberta's provincial cabinet, will allow export of the gas during a 20-year period, beginning Jan. 1, 1971.

Northern Natural, through its Canadian affiliate, Consolidated Natural Gas Ltd., Calgary, plans to export the gas to customers in the U.S. Midwest through an 800-mile pipeline. The pipeline is to be built by Consolidated Natural from Empress, Alberta, to North Branch, Minn., at an estimated cost of $280 million.

The gas-export plan also is subject to federal approval by Canada and the U.S.

Consolidated Natural had asked that it be allowed to export about 2.3 trillion cubic feet of gas during a 20-year period and, at hearings held by the Alberta agency last summer, the company's bid was opposed by Trans-Canada Pipe Lines Ltd., which argued that there wasn't enough gas in the province to support another pipeline.

Earlier this month, Trans-Canada received Alberta's approval to export another 2.3 trillion cubic feet of gas during the next 25 years, bringing Trans-Canada's total to 21.4 trillion cubic feet over a period extending to Oct. 31, 1994.

Trans-Canada plans to begin moving its additional gas to the U.S. Midwest by Nov. 1, 1970, subject to approval of the Canadian and U.S. governments.

Yesterday, in announcing its decision, the Alberta agency said it had considered Trans-Canada's opposition but that it didn't believe "that the public interest would be adversely affected by the project" of Consolidated Natural.

The board also said that it took into account the "assessment of reserves, the gas-purchase contracts and the manner in which the gas pools will likely be produced."

The proposed source of Consolidated Natural's gas is the Strachan-Rickman-Phoenix area and the Kaybob South Beaver Hill Lake Formation A pool. Both are in west-central Alberta.

The Alberta board said it was "satisfied that the reduced volume of 1.886 trillion cubic feet of gas is surplus to the present and future needs of the province and the existing permanent commitments."

Consumers Power Announces Plans For Atomic Plant

Dow Chemical Will Be Chief Customer of New Facility; Cost Put at $267 Million

Completion Is Slated in 1975

By a WALL STREET JOURNAL Staff Reporter

MIDLAND, Mich.—Consumers Power Co. said it plans to build a $267 million dual-purpose nuclear power generating plant here. Its chief customer would be Dow Chemical Co.

The facility, due to be completed in 1975, will be capable of generating 1.2 million kilowatts and 4 million pounds of steam per hour, with two nuclear reactors.

James H. Campbell, Consumers Power president, said the company has signed a long-term contract with Dow to provide all of Dow's electrical power needs from the new facility and also to provide Dow with the 4 million pounds of steam per hour for its heating and industrial needs.

Dow currently owns and operates its own coal-fired power and steam generating station, which will be closed when the nuclear plant goes into operation. Dow uses vast amounts of electric power to electrolyse brine in its chemical processes, and uses steam to evaporate brine solutions to obtain certain chemicals.

Terms Aren't Given

Neither company would disclose terms of the Dow contract, although Carl A. Gerstacker, Dow chairman, said the power and steam contract with Consumers Power is "the largest contract Dow has ever signed, either buying or selling." It was learned Dow will use about 300,000 kilowatts of the nuclear plant's 1.3 million-kilowatt capacity, with the rest of the power going into a Michigan power pool of which Consumers Power and Detroit Edison Co. are principal members.

The nuclear plant will be entirely owned and operated by Consumers Power, Mr. Campbell said. He said the company will need some type of outside financing for the project, but he declined to say what that financing might be.

Consumers Power recently disclosed plans to build a $188 million pumped-storage plant near Ludington, Mich.

Power for Ludington Plant

It is expected that excess power from the nuclear plant in low-demand time periods will be used to power equipment at the Ludington facility.

Mr. Campbell said the plant will be among the world's first privately owned, dual-purpose nuclear power generating plants. The plant here will be one of the largest yet constructed in terms of electrical output, he added.

He indicated the project wouldn't have been feasible without the contract with Dow.

Consumers Power said the Midland plant's two reactors will be of the type already in use elsewhere and won't represent any innovation in that field. Consumers Power already operates one nuclear plant and has another under construction. The building of the facility here will be subject to Atomic Energy Commission approval, the company said.

Jersey Standard Joins List of Companies To Make Nuclear Fuel

Subsidiary to Build Plant in 1970 In Washington State; Research Assigned to Battelle Institute

By a WALL STREET JOURNAL Staff Reporter

NEW YORK—Standard Oil Co. (New Jersey) joined the growing parade of private companies planning to manufacture fuel elements for nuclear reactors.

A subsidiary, Jersey Enterprises Inc., said it will build in 1970 in the Richland-Pasco-Kennewick area of Washington State facilities for development and fabrication of nuclear fuels.

Jersey Enterprises also engaged Battelle-Northwest Institute, the Richland, Wash., branch of Battelle Memorial Institute, to carry out nuclear fuel research and development prior to building the facilities. Richland is the site of the Atomic Energy Commission's Hanford Laboratories. Battelle is a nonprofit research and development organization headquartered in Columbus, Ohio.

Jersey Standard becomes the third oil company to announce nuclear fuel plans. The others are Continental Oil Co. and Kerr-McGee Corp. The project would be the ninth such private venture, involving a total of 11 companies. Nuclear fuel elements were fabricated only by the AEC until a few years ago.

Jersey Standard announced earlier this month plans for the initial mining and processing of its uranium ore reserves in South Texas.

The Jersey Enterprises project will initially develop uranium and plutonium fuel elements for use in light-water nuclear reactors, the type used commercially by electric utilities. But it also expects to later develop elements or so-called "fast breeder" reactors. These reactors, still in the research stage, will operate at much higher efficiencies, and will produce new fuel faster than they consume other fuel. Jersey also will evaluate chemical reprocessing of nuclear fuel elements.

Jersey's initial outlays for nuclear fuels research will involve just $1.5 million. But in disclosing the plans, Sen. Jackson (D., Wash.) asserted the project is "the first step in a long-range program designed to enable Jersey Standard to become a significant factor in the production and distribution of nuclear fuels to utility plants."

DEFENDANT'S EXHIBIT 173

NUCLEONICS WEEK-January 15, 1970

IN 1970: 23 UTILITIES WILL ASK BIDS ON 29 NUCLEAR UNITS

If all the U.S. utilities who are planning to ask bids on nuclear power stations this year go nuclear all the way - or even halfway - 1970 could be a respectable year for the nuclear power business. Raymond Freeman, of General Electric's corporate headquarters in New York, told the New York City metropolitan area chapter of the American Nuclear Society this week that 23 utilities were planning to request bids on 29 nuclear units this year with a combined capacity of about 30,000 Mwe. Freeman was not predicting how many would order nuclear. Last year, orders were announced for seven units, totaling about 7,250.Mwe.

DEFENDANT'S EXHIBIT 174

CHICAGO TRIBUNE
Page 16
January 20, 1970

THE ANTI-ATOM NUTS

In a significant report in Sunday's Tribune, Ronald Kotulak, our science editor, called attention to an alarming increase of opposition to nuclear-powered electric generating plants. Government and utility officials predict a power crisis, with blackouts, brownouts, and electricity rationing, in the late 1970s unless it can be averted by an unprecedented expansion program. The only way to meet the country's growing needs for power, without polluting ourselves to death, is to construct generating plants fueled by atomic energy instead of coal, oil, or gas.

Paradoxically, there is strong opposition to nuclear-powered plants from misinformed or mischievous elements of the population who say they are against pollution. This newspaper has been in the forefront of the fight against pollution of our air and water, and we believe that much more vigorous efforts by government agencies at all levels are required to prevent further degradation of our environment. But the anti-pollution campaign, like many other worthy causes, attracts many well-intentioned but emotionally-disturbed people, as well as busybodies, nuts, and others who are in bad company when they're alone.

Some opponents of atomic energy are incited by subversives whose objective is to destroy the capitalist system. Others are against all technology, like the early 19th century followers of an idiot named Ned Ludd in England, who tried to stop the industrial revolution by smashing the machines.

A modern coal-fired generating plant with a capacity of 1 million kilowatts emits 250 tons of sulfur dioxide and 20 tons of nitrogen oxides each day. The burning of coal, oil, and natural gas adds 6 million tons of carbon dioxide and 1 million tons of carbon monoxide to the atmosphere each year. Atomic plants produce no air pollutants. There is no possibility of a nuclear explosion in one of these plants. A coal-fired plant emits more radioactive materials from its smokestack than a nuclear plant. The used fuel cores of nuclear plants are safely buried, in places where there is no danger of water pollution.

Nuclear plants do discharge water, used for cooling purposes, that is 20 per cent warmer than cooling water discharged by conventional plants. Dr. Glenn T. Seaborg, chairman of the Atomic Energy commission, says the effects of this warm water on fish and aquatic plants are not fully known but are under intensive study. He favors state water quality standards which would have to be met before the AEC would issue licenses.

It is fortunate for this area that the Commonwealth Edison company of Chicago pioneered private nuclear power at its Dresden Island plant, near Morris. It has six other giant nuclear plants nearing completion or under construction which will increase its generating capacity by more than 30 per cent to 32.3 million kilowatts in 1975. It will have the largest nuclear generating capacity in the country.

A constant expansion of electric power generating capacity is essential for the nation's economic growth, on which our standard of living depends. Even more than our standard of living—our survival—depends upon the use of atomic energy for power production. In these circumstances, the government must authorize additional plants when and where they are needed, no matter how much opposition there may be.

Consumers Power Announces Plans For New Plant

Pumped Storage Facility Set For 1973; Detroit Edison To Share Cost and Output

Outlay to Total $186 Million

By a WALL STREET JOURNAL Staff Reporter

JACKSON, Mich.—Consumers Power Co. said it plans to build a pumped storage hydroelectric plant near Ludington, Mich., on Lake Michigan at a cost of $186 million.

Detroit Edison Co. will pay about half the cost of the plant and will share proportionately in its generating capacity. But the plant will be wholly owned and operated by Consumers Power, according to James H. Campbell, Consumers Power president, and Walter L. Cisler, Detroit Edison chairman.

The plant, scheduled for initial use in 1973, will be capable of generating up to 1,872,000 kilowatts of power. This will make the facility the largest pumped storage hydroelectric plant in the U.S., Consumers Power said. Currently, there are 11 such plants operating in the U.S., and the largest is an 880,000-kilowatt facility in Pennsylvania, the utility said. In addition, there are seven projects under construction, and 46 more—some generating up to 3,000,000 kilowatts—are proposed or being considered, it said.

A pumped storage power plant differs from conventional hydroelectric plants in that it stores electric generating power in the form of water in a reservoir, the company said. In the Consumers Power plant, when water is released from a 27 billion-gallon reservoir the company will build, hydraulic turbines will spin the generators, making electricity. The same equipment will pump water to the reservoir from Lake Michigan by reversing the direction of rotation. Thus the generators become electric motors, driving the turbines as water pumps.

Mr. Campbell likened the water-storage type plant to "a giant storage battery" for quick use at a time of peak demand. "In off-peak hours, when customer demand is lowest—such as late at night or on weekends—water will be pumped from the lake and stored in the reservoir," he explained. "Then, at time of maximum demand, the water will be released, generating electricity on its way back to the lake."

"We'll be able to add significantly to our generating capacity; rapidly if necessary," he added.

FPC Aide Again Approves Con Edison Bid To Build Power Project; Protests Likely

A Wall Street Journal Power Reporter

Consolidated Edison Co. won Federal approval for the second time for a bitterly opposed giant $660.5 million pumped storage hydroelectric project on the Hudson River near Cornwall, N.Y.

A Federal Power Commission examiner recommended that the New York City utility be permitted to proceed with the project. It has sought since Jan. 23, 1963. The FPC approved it March 6, 1965, but on Dec. 20, 1965 a U.S. Court of Appeals set aside the Federal license and ordered examination hearings.

Opponents have 30 days in which to protest the ruling, and it is considered likely they will do so. If no protests are filed, and the FPC doesn't order a review of the hearing, the decision could be final in 60 days.

Charles F. Luce, Con Edison chairman and chief executive officer, said if the license is issued for the Cornwall project, "our company can move ahead rapidly with several phases of our program to improve service to customers."

The project has been contested chiefly by conservation groups. Objections initially were aimed at charges that the plant would mar the beauty of historic Storm King Mountain at a scenic spot on the Hudson near West Point. But Con Edison agreed to put the plant and part of its power transmission lines underground. Opposition has since revolved chiefly on such points as potential damage to fish spawning areas.

FPC Examiner Irving C. Stenger rejected as "not persuasive" arguments that the Con Edison project would be harmful to marine life. He also rejected claims that Con Edison hadn't complied with the Federal Power Act's comprehensive planning requirements regarding development of the Cornwall area. The utility plans public parks both around the inland reservoir and along the new dredged river front near the plant.

Con Edison has estimated it would take about three years from start of construction to have the first hydroelectric turbine in operation, and about four years to have all eight turbines on the line. The project would be capable of generating 2 million kilowatts of power on peak, one of the largest pumped storage projects in the world.

Pumped-Storage Theory

The theory behind pumped storage is related to the great fluctuations in daily power use. A reservoir of considerable height above the power plant releases water through the plant's turbines to generate power at peak demand periods of the day. During hours of low power use, electricity from other plants is used to reverse the turbines and refill the reservoir with water from the river.

The reservoir for the Cornwall project would be located 1,320 feet above the Hudson in a 300-acre natural depression between Storm Mountain and Mount Misery, about one mile southwest of Storm King. It would be on the site of the municipal water reservoir for the town of Cornwall, and Con Edison would build a new water reservoir for the town.

Water would flow to the power plant through a 20,000-foot long, 40-foot diameter tunnel through the mountains. The plant would be placed in underground galleries hewed out of rock north of Storm King Mountain, on the Hudson's west bank, about 40 miles north of New York. Power lines would travel under the Hudson River and underground three-fourths of a mile on the east bank before surfacing for conventional overhead lines.

Examiner Stenger recommended an additional 3.9 miles of underground of power lines and some altering of the proposed route of overhead lines.

Con Edison asserts that the Cornwall plant would provide extensive protection against a massive power failure such as the great Northeast blackout of Nov. 9, 1965. It says that Cornwall's power could be started up within minutes to meet a sudden emergency.

Mr. Luce said, "The availability of Cornwall to provide a large supply of power at a moment's notice in case of emergency will strengthen the reliability of power supply for the entire Northeastern region of the U.S."

Cite Air Pollution

Delay of the Cornwall project has forced Con Edison to build a 200,000 kilowatt coal-fired plant on Staten Island it otherwise wouldn't have needed, and has prevented scheduled closure of parts of four obsolete coal-burning plants in Manhattan. This has hurt the company's efforts to cut costs and has hampered the city's efforts to reduce air pollution, Con Edison officials assert.

Cornwall will enable Con Edison "to reduce even further our share of the air pollution in the New York City area by shutting down older and less efficient coal and oil burning plants," Mr. Luce said.

The court ruling ordering reconsideration of the Cornwall project was considered significant because it forced the FPC to consider economic and conservation issues in granting licenses for power projects. But it also brought about changes from some in the power industry of excessive opposition by conservation interests being to the detriment of power users.

TVA Plans to Start $155 Million Project At Raccoon Mountain

Plan Will Include 4 Reversible Pump-Turbine Units With Total Capacity of 1.4 Million Kilowatts

By a WALL STREET JOURNAL Staff Reporter

KNOXVILLE, Tenn.—The Tennessee Valley Authority said construction of its $155 million Raccoon Mountain pumped storage hydroelectric project near Chattanooga will begin in mid-1970.

Preliminary studies and investigations for the project have been under way for several years. The system uses power at off-peak hours to pump water to a reservoir where it is stored for making electricity when demand is heavy.

TVA said the project will include four reversible pump-turbine units with a total generating capacity of about 1.4 million kilowatts. The units are planned for an underground powerhouse to be carved out of rock inside the mountain.

The project will include a mountaintop reservoir covering about 800 acres with a tunnel some 30 feet in diameter to drop water from the reservoir to the powerhouse below and out to a nearby lake, TVA said.

The four units are scheduled for operation in 1974 and 1975. Construction will be financed with proceeds from the sale of TVA bonds and with revenue from power sales, TVA said.

TVA said its studies show that additional capacity required to meet system loads during 1974 and 1975 "could be provided at lower cost by the Raccoon Mountain project than with the alternative of steam-electric units."

THE GEYSERS WITH FUMAROLES IN CALIFORNIA

Power from a leaky crust.

GEOPHYSICS

Percolators in the Earth

While chasing a grizzly bear one day in 1847, Explorer-Surveyor William Bell Elliott blundered into a canyon that looked to him like "the gates of Hell." Huge, spiraling columns of steam hissed out of the ground; the earth trembled beneath his feet. "The Geysers," as he named the hill-rimmed valley 85 miles north of San Francisco, is as awesome as ever. But its frightening bursts of steam are now being harnessed. The canyon is the site of the first commercial geothermal-power plant in the U.S., and the installation has paid off so handsomely in eight years of operation that it has set off a small "steam rush" in the Far West.

As old as the earth itself, natural steam is a familiar source of heat and power in countries as widely separated as Italy, Iceland and New Zealand. The renewed interest in the U.S. springs from a growing population's need for more electricity. In some areas, geothermal steam offers a cheap, ready-made alternative to coal, oil and nuclear fuels, and it leaves no pollutants in the air. At The Geysers, steam-driven turbines produce 58,000 kw. of electricity at a cost 23% below that of nearby conventional generating plants; in a few years, the area could be producing almost 20 times as much.

Prospecting for Steam. The largest and most accessible steam fields are located west of the Rockies, where volcanic activity has brought molten, lava-like rock known as magma close to the earth's surface. The 1,500° F. magma either releases its own trapped water as steam or, like a gigantic coffee percolator, vaporizes water that has seeped down into the earth.

Occasionally steam emerges through fissures in the ground called fumaroles (from the Latin word *fumariolum*, meaning smokehole), and the simplest way to prospect for this geothermal energy is to look for such vaporous leaks in the earth's crust. But in areas where the energy remains trapped underground, geologists must use more sophisticated techniques. One method employs infra-red aerial photography. Since the infra-red film is sensitive to heat, geothermal areas are likely to show up lighter in the picture. Another method measures the earth's electrical conductivity, which increases with the presence of subsurface hot water. To tap the subterranean energy, engineers drill with standard oil rigs, going down as little as 600 ft. or as much as 8,000 ft., the depth of the world's deepest steam well at Salton Sea near Brawley, Calif.

The Monster. The job can be dangerous as well as difficult. At The Geysers, a new well erupted with such furious force that the scalded workmen were convinced they had tapped a live volcano. To cool it off, they pumped in cold water until a nearby stream ran dry. Then they tried a concrete plug, without success. "The Monster," as they dubbed the well a decade ago, continues to spout.

Such unrestrained power holds enormous promise. Engineers estimate that by 1980, geothermal energy could be generating as much as 10% of the total electrical output of the U.S. And no matter how much is used, the heat is not likely to be used up. Once scientists master the technology, they should be able to recirculate condensed steam back into the ground, giving virtually unlimited life to wells in states as dry as Nevada. Even without such recirculation, Italy's 64-year-old Larderello geothermal-power plant near Siena, where fumaroles gave Dante earthly inspiration for his Inferno six centuries ago, is still going strong.

DEFENDANT'S EXHIBIT 179

CHICAGO DAILY NEWS
Page 45
January 9, 1969

This is Geothermal Resources Well No. 1 in Sonoma County, Calif. There's a steam rush today in the country that had a gold rush 120 years ago.

Earth's own power source

By Dean C. Miller
United Press International

If man succeeds in tapping and harnessing the giant steam boiler below the earth's crust he will have enough power to run his factories, heat and light his homes, and launch his space probes for centuries.

U.S. companies in recent months have decided to drill seriously for geothermal power locked in the earth's molten center.

The resultant "great steam rush," like the "great gold rush" 120 years ago, was centered west of the Rockies. The rigs are especially active at the geysers about 90 miles north of San Francisco, where Pacific Gas & Electric Co. has been producing electricity since 1960 from steam created by molten rock or magma under the earth's surface.

PG&E plans a 250,000,000 complex capable of generating 250,000 kilowatts, enough to "turn on" San Francisco.

Oil companies also are in the steam race. Occidental Petroleum, Sun Oil and Union Oil are prospecting.

Some scientists estimate 10 per cent of the U.S. electricity will come from such wells by 2000.

The potential is staggering. Power from steam wells will be virtually inexhaustible when a technology permitting recirculation of condensed steam back into the ground is refined.

LIKE NUCLEAR power, geothermal energy is being touted as the energy source of the future. And it has the added advantages of being cheap and non-polluting.

Burning Refuse to Be Used In 'Total Energy' Concept

By a WALL STREET JOURNAL Staff Reporter

NEW YORK — Refuse collected from tenants will provide part of the fuel supplying all electricity, heat and air conditioning for two shopping centers to be built in Joplin, Mo. and Middletown, N.Y.

Two small New York companies announced plans for combining refuse disposal with the so-called "total energy" concept of supplying all energy needs with on-site plants.

Combustion Equipment Associates Inc., a maker of air and water pollution control devices, will design, manufacture and maintain a refuse collection and disposal system for the two projects. It said the system will be "pollution free."

Total Energy Leasing Corp., which owns and leases on-site total energy plants, will lease the refuse system for use in its total energy units at the two shopping centers.

Some European cities, Montreal and the U.S. Navy have constructed plants that generate steam by burning refuse. This steam, in turn, is used for generating electricity and for heating. The new projects, however, would carry the principle a bit further by combining it with the total energy approach.

AFFILIATION IS FAST BECOMING A NECESSITY

Consolidation of power systems in the U.S. today is fast becoming a matter of economic necessity.

For the past five years economies of scale have steadily pointed to the merits of better coordinated operation and mutual location, timing, sizing, and ownership of system facilities among neighboring interconnected utilities. The industry has steadily moved in this direction.

Today the tempo has quickened. Impact of the mounting new capital requirements, soaring interest rates, sagging rates of return, and the touchy legalities of coordination for reliability are fast making corporate partners out of friendly neighbors.

The issue today is not so much *whether* to integrate contiguous systems as it is *how* and *when*. Affiliation is getting the nod more often than outright absorption of one company by the other. The reasons are plausible. Affiliation leaves corporate identities intact, minimizes personality and personnel conflicts, maintains local company identity, preserves prestige, and simplifies and accelerates the journey toward the coordinated planning and operation.

These affiliations all tend to optimize operating savings which in some instances, even among groups of limited size, can amount to upwards of $2 million a year. Common purchasing of stock items in carload lots can bring savings of 10-15% and substantial amounts on fuel purchases. Mutual standards offer economies by eliminating minor differences in specifications and settling on fewer types of materials and equipment.

In another area, operation of a mutual engineering and design department, research and development, the consolidation of heavy construction forces, sharing of testing departments, and the operation of mutual standardization and metering laboratories can bring further savings.

All of these considerations soften and can perhaps offset the declining rate of return created by mounting money rates and escalating costs of material and equipment in the face of expanding system needs to keep pace with mounting loads.

But as we see it, perhaps the most far-reaching and significant influence in the creation of affiliations is related to the legal and financial complexities involved in true coordination of power pools and interconnected systems to attain the ultimate in bulk power reliability. It is difficult in the extreme to conceive how agreement could be reached—short of affiliation—among members of a pool or interconnection where extensive reinforcement to the fringe area of a remote system is paramount to the reliability of a nearby metropolitan load center.

And so it is that we say that merger and affiliation of power systems today is no longer a comfortable convenient thing to do, but it is fast becoming a matter of industry necessity.

New England Affiliation Slated

Three Concerns Involved

The boards of the Boston Edison Company, Eastern Utilities Associates and the New England Electric System had approved a plan to combine under a single parent organization, the Eastern Electric Energy System, the companies announced yesterday, continuing the trend toward "affiliations" of utilities on a regional basis.

The new company would be a Massachusetts business trust with operating subsidiaries serving about 1.6 million electric and gas customers in 261 towns in parts of Massachusetts, New Hampshire and Rhode Island. The announcement was made jointly by Cleveland F. Anslie, chairman of Boston Edison; Guido R. Perera, president of Eastern Utilities; and William Weissner, chairman of New England Electric.

The three executives said the decision to unite followed an analysis of studies made over the last several months by both the individual companies and outside consultants. The studies indicated such a move would be "in the interest of shareholders and customers and

UTILITY CONCERNS PLAN AFFILIATION

Continued From Page 61

should produce benefits to the New England regional economy."

Under the terms of the agreement, stockholders of Boston Edison common would receive 1.85 shares of Eastern Electric Energy for each share held. Holders of Eastern Utilities would receive 1.134 shares of the new company's common stock for each share held after giving effect to its 2 for 1 stock split on last May 31 and owners of New England Electric common would receive one share of Eastern Electric Energy for each share held.

Year Needed for Approval

It is expected that at least one year would be required to obtain the necessary approvals of the Securities and Exchange Commission, the Federal Power Commission and the Massachusetts Department of Public Utilities.

Combined assets of the new company as of last Dec. 31 would have been in excess of $1.5-billion, making it the eighth largest power system in the nation. Total operating revenues would have been $487-million and net income would have been about $55-million. It would be the twelfth largest in country in kilowatt-hour sales and 12th in electrical

This latest affiliation of utilities continues to bear out the prediction of Donald C. Cook, president of the American Electric Power System, who said that the day is coming when there will be no more than a dozen or so utilities across the nation.

New England Network Seen

Utility observers also hailed upon yesterday's announcement as hastening the day of an all-New England utility network made up of Northeast Utilities, itself a relatively new holding company, and the new Eastern Electric Energy, plus various independent companies throughout the six-state area.

In fact, Northeast Utilities, New England Electric and Boston Edison went into lengthy preliminary investigations of a possible affiliation back in 1966. This would have produced a system with assets of more than $3-billion putting it into the top three in size in the industry at that time.

Northeast Utilities broke off negotiations on Jan. 31, 1967 and the three announced then the move "was not intended to bar eventual affiliation but was a temporary action to give Northeast an opportunity to complete internal adjustments arising from its earlier mergers."

Boards of Iowa P&L And Iowa-Illinois G&E Approve Merger Plan

New Entity, Iowa Energy Corp., Plans to Retire the 2 Utilities' Outstanding Preferred Shares

By a WALL STREET JOURNAL Staff Reporter

DES MOINES, Iowa—Iowa Power & Light Co. and Iowa-Illinois Gas & Electric Co. said directors of both companies approved a plan to merge the concerns into a new corporation to be called Iowa Energy Corp. The merger previously had been approved in principle.

The consolidation plan provides that outstanding shares of preferred stock of the two companies will be retired by the new corporation at the rate of 8,000 shares annually. The preferred shares will be exchanged for Iowa Energy preferred shares on a share-for-share basis with equivalent dividend rates, redemption and liquidation prices and similar rights and preferences, the companies said.

Under terms previously announced, Iowa Energy and Iowa-Illinois common stock will be exchanged on a share-for-share basis, and 1.15 shares of Iowa Energy will be issued for each Iowa Power common share. Iowa Power has 3.2 million common shares outstanding, and Iowa-Illinois Gas has 5.1 million.

The two utilities entered into a memorandum of intent in September 1967 to combine under a holding company arrangement. They attempted to attract other gas and electric utilities in Iowa into joining the plan, but were unsuccessful. The two utilities said last month a merger was being explored as "a possible alternative to the holding company proposal."

Ayrshire Collieries Asks Bids of 5 Firms

Coal Concern Invites Offers to Purchase or Merge With It; Replies Expected Next Month

By a WALL STREET JOURNAL Staff Reporter

INDIANAPOLIS—Ayrshire Collieries Corp. has invited five companies to submit either sale or merger proposals, according to a letter sent to stockholders.

The five companies weren't named. Plans for either the sale or merger of the coal company were disclosed early this year.

Proposals are expected to be received in December from all five companies, the letter said. But shareholders were told that because of the possibility that any negotiations or agreement will "involve complicated types of transactions," it may be two or three months before additional information can be supplied.

"Because of complications, we believe it's in the best interests of stockholders not to make any further announcement until a definite agreement has been reached for the sale or merger of the company," the letter stated.

Lovett C. Peters, former executive vice president of Cabot Corp., said, "It appears Ayrshire would be more valuable to others than to Ayrshire stockholders." Mr. Peters was hired last February to act as agent in any transaction.

Questioned as to the management's reasons for selling the company, Pierre F. Goodrich, chairman, said, "Proper action by directors includes not only management but also consideration of a sale or merger if it appeared to be in the stockholders' best interests." He declined further comment.

Ashland Oil Plans To Buy or Lease Ayrshire Assets

Boards Vote Proposal That Includes the Sale of Coal Royalties to Third Firm

Pact Involves $125 Million

By a WALL STREET JOURNAL Staff Reporter

ASHLAND, Ky.—Ashland Oil & Refining Co. and Ayrshire Collieries Corp. said directors approved a proposal involving acquisition or lease of Ayrshire's assets by Ashland.

Ayrshire Collieries produces coal, with operations primarily in Illinois, Indiana and Western Kentucky. The company has substantial reserves west of the Mississippi River.

The announcement said Ayrshire would receive for its assets an aggregate of approximately $125 million, with at least $95 million to be derived from sale of reserved coal royalties. The balance of the sale price would be paid by Ashland in cash or common shares having the same market value.

Reserved coal royalties, including mining rights and related mining equipment, will be sold by Ayrshire to third parties, and thereafter operated under a lease providing for the payment of royalties on coal produced.

Such "production payments" are common in transactions involving large reserves of oil or minerals in the ground, and have been used in other recent acquisitions of coal companies. A spokesman for Ashland said a leasing arrangement is relatively new in the coal industry, but is common in the hard minerals industry.

The proposal contemplates that Ayrshire will pay from the proceeds of the sale approximately $19,625,000 principal amount of long-term debt of Ayrshire and its subsidiaries. On liquidation, Ayrshire shareholders are expected to receive, after payment of certain expenses and taxes related to the sale, cash or cash and [illegible] with an aggregate value of $30 a share.

Orin Atkins, president of Ashland, and Pierre F. Goodrich, chairman of Ayrshire, said the transaction is subject to completion of definitive agreements providing for the sale by Ayrshire of all of its assets, approval by Ayrshire shareholders, receipt of a tax ruling, and other necessary approvals.

Ayrshire in 1968 had sales of approximately $80 million. The company produces approximately nine million tons of coal annually.

Ashland Oil, which had 1968 sales of more than $1 billion, refines and markets petroleum products, petrochemicals and chemicals.

Mr. Atkins had told the Ashland annual meeting Monday that a number of other companies were also bidding for Ayrshire. He said the coal company had coal reserves of more than 2 billion tons.

Ayrshire is located in Indianapolis.

Metal Climax, Ayrshire Sign Merger Accord

Acquisition of Coal Producer By Metals Firm Valued at Minimum of $62.6 Million

Boards and Holders to Vote

By a WALL STREET JOURNAL Staff Reporter

NEW YORK—American Metal Climax Inc. and Ayrshire Collieries Corp. said they signed a letter of intent "looking toward" the merger of Ayrshire into Metal Climax in a transaction currently valued at a minimum of $62.6 million.

The acquisition of Ayrshire, an Indianapolis-based coal producer, would mark Metal Climax's first move into the coal business. Metal Climax is a major producer, fabricator and marketer of metals and minerals, including molybdenum, potash, copper, lead, zinc, iron and aluminum.

Talks aimed at the acquisition of Ayrshire or the leasing of its assets to Ashland Oil & Refining Co., Ashland, Ky., were called off earlier this month. At that time, Ayrshire said it was holding discussions with another company, which it didn't identify.

Under terms of the Metal Climax-Ayrshire agreement, Ayrshire stockholders would receive one share of a new class of Metal Climax convertible preferred stock for each of the 7,027,000 Ayrshire common shares. The new Metal Climax preferred would have a dividend rate of $4 a share through 1971 and $5.25 a share thereafter. It would be convertible into the company's common stock on a formula based on the price of the common between now and May 31, within a convertibility range of 1¼ to 1 2-3 common shares for each preferred share.

On the basis of Metal Climax's closing price on the New York Stock Exchange yesterday of $62.75, up $1.125, the proposed transaction would have a minimum value of $62.6 million and a maximum value of $80.5 million.

The agreement is subject to ratification by directors and shareholders of both companies. It's contemplated that the transaction would be tax-free to Ayrshire holders.

Ayrshire mines coal in Indiana, Illinois and Kentucky, predominantly by the open-pit method. In the fiscal year ended June 30, 1968, the company earned $4.3 million, or $0.94 a share, on sales of $69.7 million; in the first half of fiscal 1969, the company earned $1.1 million, or $1.45 a share, on sales of $32.6 million.

Coal production from its nine mines is about nine million tons a year. Two new mines are under development and annual production is expected to increase to about 18 million tons by 1972. The coal is sold primarily to electric utilities.

Metal Climax earned $67.4 million, or $4.36 a share, in 1968 on sales of $970.5 million.

Last year, Kennecott Copper Corp., the largest U.S. copper producer and a major foreign copper producer, acquired Peabody Coal Co. in a diversification move.

Air pollution authorities urge use of "clean-burning" natural Gas.

DEFENDANT'S EXHIBIT 187

Today, more and more apartment building owners are turning to Gas heat. Things stay cleaner inside and out.

What you've read in newspapers, magazines and heard on television is true. Air pollution is fast becoming more of a threat than ever. Like most of our major cities, Chicago is facing a big problem.

Polluted air is dangerous. It isn't something one person can suddenly stop. It's the concern of all of us. And more and more apartment building owners are turning to natural Gas. You see, natural Gas burns cleaner. That's why natural Gas is now recognized as a good way to help keep city air cleaner. And air pollution authorities are saying as much in other large urban centers.

If you own an apartment building, it makes good sense to consider clean-burning natural Gas. Gas makes good money sense too, because Gas is economical. Your tenants will be happier too, because natural Gas helps to keep apartments clean. And with natural Gas, you can be sure you will be doing your part for a cleaner Chicago. Like a fresh idea? This one lets you breathe a little easier.

DEFENDANT'S EXHIBIT 186

1977 THE YEAR OUR CITY DIED.

If the increasing pollution of our air is not reversed, Philadelphians might have to move. Or both adults and children will gasp for fresh air and get sick with dangerous respiratory ailments.

Could this nightmare come true? Yes. The special air pollution report to New York City's mayor warns that this could happen to major cities—including Philadelphia—within 7-10 years. Unless prompt action is taken to bring air pollution under control.

Just a few weeks ago an air pollution alert sounded in Philadelphia. Fortunately, a change in the weather broke up the inversion before pollution reached dangerous levels. But next week or next month, we may not be so lucky.

One important step to reduce air pollution is for industry to change to fuel that does not contain sulfur. A fuel like natural gas, a non-pollutant. And PGW has encouraged this change by reducing gas rates to large users twice in recent months. For facts on big-volume gas rates, or to explore the advantages of using gas, write direct to us. Or call 796-4273.

You can heat 2½ houses with modern oil for what it costs to heat 1 house with electricity!

No doubt about it. Just take your oil bill for last winter. Multiply by 2½. That's about what electric heat would cost. Let's say your oil bill was $200. Then, electric heat would cost about $500. You pay $300 more every year. Over a 20-year mortgage your oil savings of $300 a year could add up to over $10,000*. It's easy to see what a fortune you save with oil heat!

You save in other benefits, too. No fuel is cleaner than oil. (Take an electric clock off the wall. Look at the smudge.) No fuel is more powerful. (Oil heats water 5 times faster than electricity.) No fuel is safer. (With oil — no red hot wires all over the house.) Individual room temperatures? You can have that with any fuel. But what for? It means running around changing seven or eight thermostats all the time and keeping doors closed between rooms! Who needs it?

Why pay so much more and get so much less? Stay with modern oil heat and count your blessings. Count your money, too!

We're helping Main Street switch to nuclear power.

Nearly half of recent generating capacity commitments are nuclear. Worthington, a leader in many phases of conventional power generation, is directly involved in the switch.

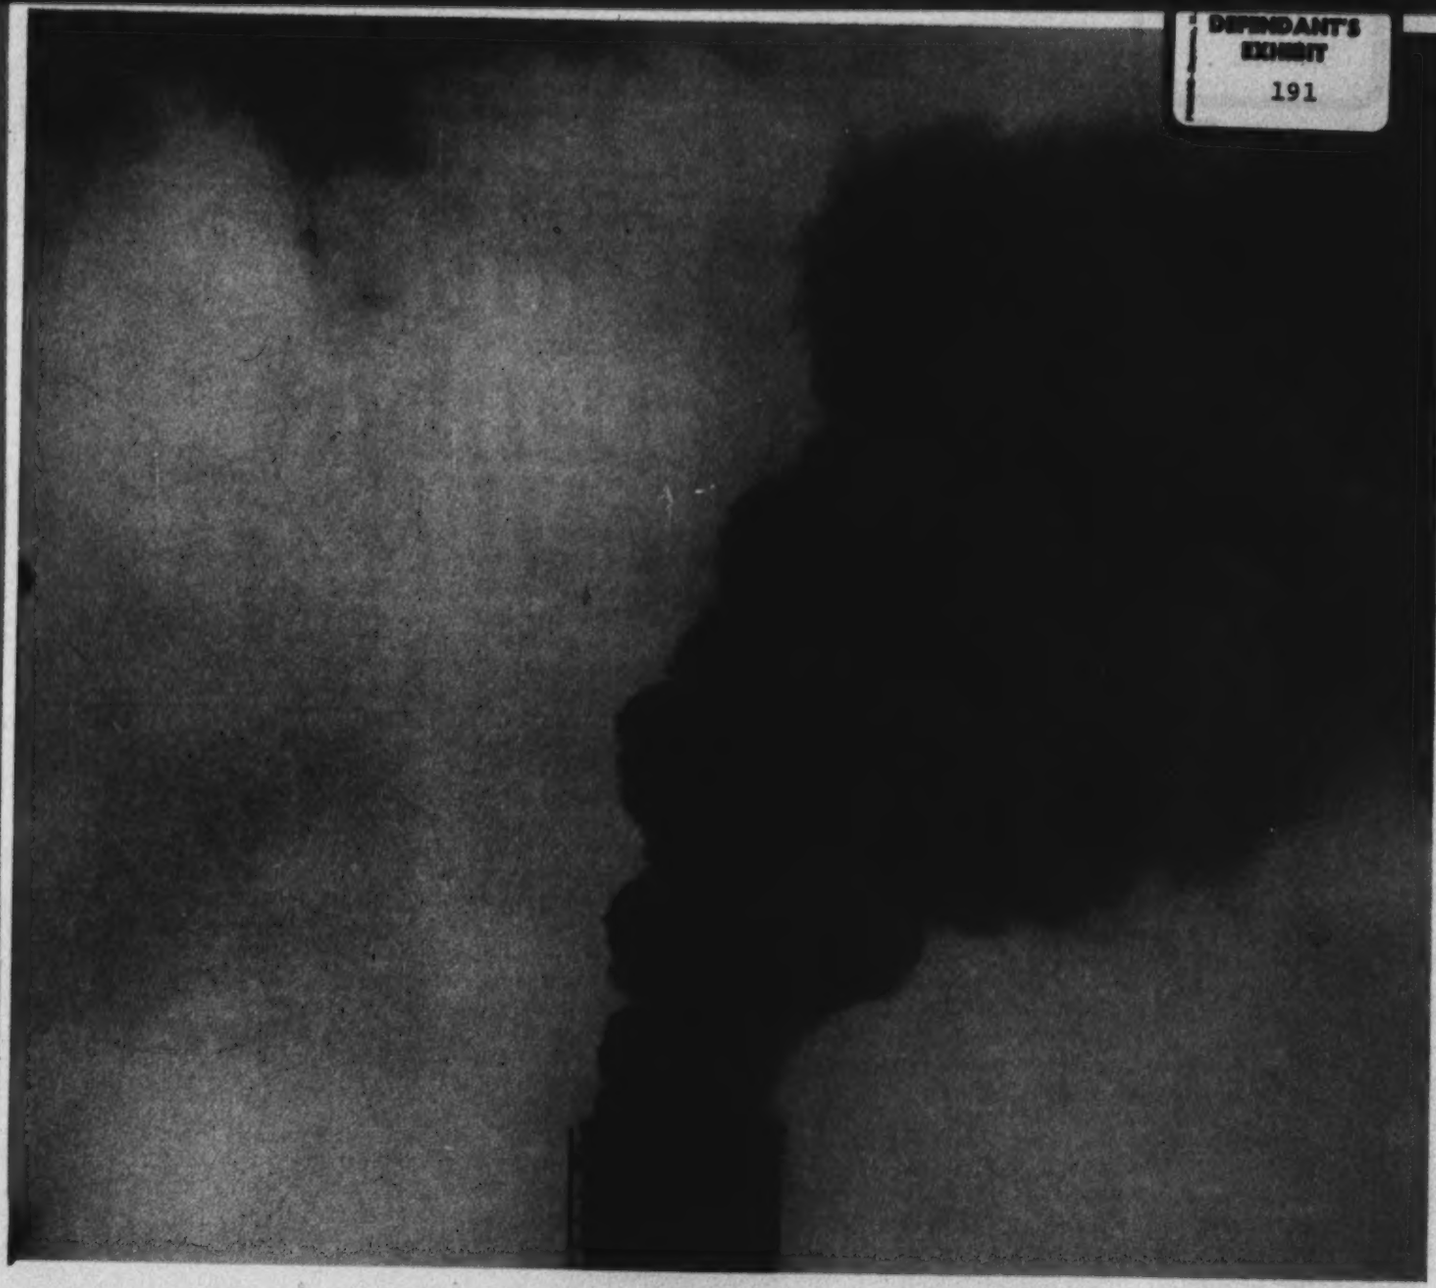
Our jet gas turbines and diesel engines can supply the energy to start up nuclear plants. Our control valves, boiler feed pumps, motors and feedwater heaters are in plants under construction. And we've shipped the largest twin-shell, multi-pressure nuclear steam condenser.

In fossil fuel plants, we've shown the way with many developments in major steam plant auxiliaries. And we have many innovations in our complete turbine, diesel and jet gas turbine generating units used for base load, peaking or emergency standby.

Helping generate power for industry and people is one of many ways Worthington helps serve man's basic needs: for energy, food, water, transportation, and health and sanitation.

WORTHINGTON
SERVING MAN'S BASIC NEEDS WORLDWIDE

DEFENDANT'S EXHIBIT 191



This pollution was caused by burning money.

How much of it was yours?

Where there's smoke, there's incomplete combustion. When it comes from a boiler plant, someone has paid for fuel that didn't burn. What doesn't burn gives no heat. Someone's money has gone up the chimney in smoke. Which makes not only bad air, but very bad economics.

What makes *good* economics is to put in a modern Todd burner with the sonic fuel atomizer—as replacement for older burners (coal or oil), or in new construction. Combustion efficiency with sonic atomization: 98% and often higher. It keeps your chimney smokeless, even with residual fuel oil.

Using sonic energy to boost boiler performance is the first really new development in fuel atomization in 50 years. It is also a Todd exclusive.

Be selfish. Fight air pollution. Have your engineering department write Todd today for design information. Department F., 120 Park Avenue, New York, N.Y. 10017.

DEFENDANT'S EXHIBIT 192

What's Gas Energy doing to make industry nice to be near?

This industrial chimney is in full-time operation. Where's the smoke? There isn't any because it's using clean-burning Gas Energy.

Gas Energy is helping to get rid of plant waste before it becomes a community air pollution problem. By using economical Gas for waste incineration and heat processing, more and more plants are contributing to clean air in their communities.

But Gas incineration is more than good public relations, it's good business. Because Gas cuts operating costs for processing and waste disposal. And high temperature incineration is effective because Gas burns clean. And without odor.

Modern Gas incineration can dispose of liquid, gaseous, and solid wastes. And heat from incineration can be recovered for industrial processing. Or for plant climate control.

The problem of air pollution is receiving public and legislative attention. So industry must solve its diverse and complex problems of gaseous, liquid, and solid waste disposal. And research in the Gas Industry is playing an important role in solving these problems.

But is this really so surprising? After all Gas is almost pure energy.

AMERICAN GAS ASSOCIATION, INC.

1174

DEFENDANT'S EXHIBIT 193

How nuclear science may give America more Gas energy.

It happened in December, 1967. With a muffled boom from the release of energy equivalent to 26,000 tons of TNT. A nuclear explosion that was part of Project Gasbuggy. It was an experiment designed to put nuclear explosives to work on their first peaceful, industrial application.

The explosion took place 4,240 feet underground. Its purpose was to heavily fracture the Gas-bearing rock in a remote area of New Mexico. That way, more Gas could move through the rock and to a wellbore.

With conventional explosives, estimated recovery of Gas at the Gasbuggy site would be about 10%. But a nuclear explosive, by vastly increasing escape space in Gas-bearing rock, was expected to increase recovery to an estimated 70%.

Working with the Atomic Energy Commission and Department of Interior, the Gas Industry is planning for the future. There is great optimism that this and other experiments will make it possible for America to have more energy for better living tomorrow.

But is this all really so surprising? After all, Gas is almost pure energy.

DEFENDANT'S EXHIBIT 194

BOILER CONVERSION?

Get the 5 advantages Gas power-type burners give you in full measure.

Here they are: efficiency, safety, durability, economy, and cleanliness.

You see, Gas power burners work by forced injection of primary and secondary air. This provides perfect control of combustion, regardless of variable chimney drafts. No high chimney or induced draft fan is needed. Just a short vent stack, properly sized.

That's efficiency and economy. So is the way Gas burners come completely assembled for quick and easy installation. Safety? Factory-tested Midco Lo-Blast power burners, for example, come with dual-type constant safety pilots as the standard control system. And other safety systems are also available.

Cleanliness? Nothing burns cleaner than Gas. Or more economically. Gas burners are durable. No replacement worries.

Midco converts an apartment and the service staff is cut by 2/3.

When the University of Chicago bought a hotel for residential use, one of the first steps was conversion to Midco Lo-Blast burners. Instead of three full-time engineers plus two relief men, the 10-story building's heating system is now serviced by one man. And the Midco 6,000,000 BTU/hr burner operates so automatically that 95% of his time is available for other duties. Also reduced: noise and dirt.

Are you converting? Better get details on Midco burners from your local Gas Company Sales Engineer. Or write: Mid-Continent Metal Products Co., 2717 North Greenview Ave., Chicago, Ill. 60614.

Pretty soon you may be making your own electricity from natural gas.

Every light in the house and more than a dozen appliances operating at the same time... *most* of the time.

How'd you like to pay this electric bill?

A few years from now you just might not mind at all. Because you might not have an "electric bill". You, and the owner of this home, may be able to produce all the electricity you need with a "fuel cell" powered by natural gas. The same natural gas that saves you so much money on heating, cooling and cooking today.

The gas fuel cell makes electricity chemically. Natural gas is piped in. It takes a safe chemical bath... and comes out electricity! Enough electricity for lights, TV, stereo, kitchen appliances, power tools and all the little labor-saving, luxury-living gadgets that are here today or on their way.

When can you order yours? Not just yet... but maybe sooner than you think. We have a working model of the gas fuel cell now. And yours could be ready before long. If you have natural gas, you're all set. For you, we're going to make electricity as economical and dependable as natural gas.

There's a lot more coming from natural gas energy.

Northern Illinois Gas Company

Another shopping center finds that making it's own electricity is the best buy.

Waukesha Gas Energy Systems produce electricity for lighting, heating and cooling.

Building a big shopping center can easily give you some big headaches. Especially when you begin thinking of utility costs for lighting, heating and cooling.

That's why the owners of Turfland Mall in Lexington, Kentucky, chose a Waukesha Gas Total Energy system.

How does a Gas Total Energy System work? Gas-fired Waukesha Enginators** provide all of the electricity the shopping center needs. In the process, huge amounts of engine heat are produced. But this heat doesn't go to waste. Because in a Gas Total Energy system it's recovered and used. For heating, cooling, and hot water. **Waukesha's factory-tested family of engine-generators.

This thermal efficiency is the reason a Gas Total Energy system is so economical. In fact, installations of this kind can be more than twice as efficient as today's best steam electric generating stations.

And with a Waukesha Gas Total Energy system, area power failures are not a problem. Because all the power is dependably produced on the site. Not from a distant source.

So even if the lights go out for everyone else, this shopping center and its customers are never affected.

Economical Gas Total Energy systems are working in schools, buildings, shopping centers, and plants around the country. Can it work for you? Find out from your Waukesha representative. Or the local Gas Company Sales Engineer. There's no reason why you can't get in on a good buy, too. • AMERICAN GAS ASSOCIATION, INC.

For all your energy needs, Gas makes the big difference.

AG-14983—This advertisement appears in Buildings, January; Heating, Piping and Air Conditioning, February; Architectural Record, [illegible]

Sheraton-O'Hare reduces utility costs over 50%.

Waukesha Gas Engines produce electricity, cooling and heating.

Suburban Chicago's Sheraton-O'Hare made a drastic cut in utility costs by going to Gas Total Energy. But economy was only one reason why this major hotel stopped buying electricity. The memory was still vivid of the 72-hour electrical service break caused by a 1965 ice storm. So they also wanted the dependability and security of a Total Energy System.

Four Waukesha Gas-fuel engines are at the heart of the system. The Waukesha engines drive electrical generators. Two of them handle the daily utility load. Two others stand by for emergency and for future expansion. (Including a planned convention center.)

What makes a Gas *Total* Energy System? The heat of the engines is recovered and put to work for absorption cooling, heating and hot water.

This unique combination of economy, efficiency and reliability is why so many commercial buildings are choosing Gas Total Energy.

Learn more about what Gas Total Energy can mean to you. Consult with your Waukesha distributor or contact your local Gas Company Sales Engineer.

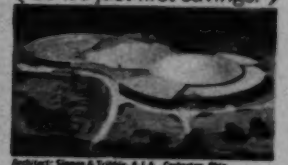
School Board chooses Gas heat over electric and saves over $50,000.

(That's just on first costs. So it's just first savings.)



Architect: Elgner & Tribbie, A.I.A., Columbus, Ohio
Engineer: Ballard & Assoc., Canton, Ohio
Gen. Contractor: Columbus Roofing & Insulating Co., Columbus, Ohio

The School Board of Ridgewood High in West Lafayette, Ohio got Gas and electric heat bids from independent contractors.

Here's what they found: Electric came in at $2.59 per square foot for the 60,000 square foot school. The Gas bid was only $1.95. The difference adds up to a big $38,200.

Another first-cost savings came from the $15,000 that the school didn't have to spend on heavier wiring and the sophisticated controls needed with electric heat.

But the savings from Gas heat go on. Because the operating economy of Gas goes on for as long as you use it.

This school is no isolated case. There are many other studies that have proved the value of competitive bids when you want the best heating value.

So if you're looking for a heating system for a school or any other installation, take a good look at Gas heat. Just call your local Gas Company.

AMERICAN GAS ASSOCIATION, INC.

For school heating, Gas makes the big difference.

This new school uses Gas Energy for heating, cooling and electric power and saves $1,000 a month.

When the architects designed Catholic Central High School in Greater Muskegon, Michigan, they chose a Gas Total Energy system. The result has been savings estimated at $6,300 on power and heat generation in just six months.

One of the big ways this system saves is in the recovery of by-product heat. Heat from the combustion engines is recovered for absorption cooling, space and water heating. This efficient use of Gas Energy helped make this one of Michigan's most economically built and operated high schools.

Consider Gas Total Energy for your new buildings. Your local Gas Company Sales Engineer can give you more information.

AMERICAN GAS ASSOCIATION, INC.

Gas makes the big difference.

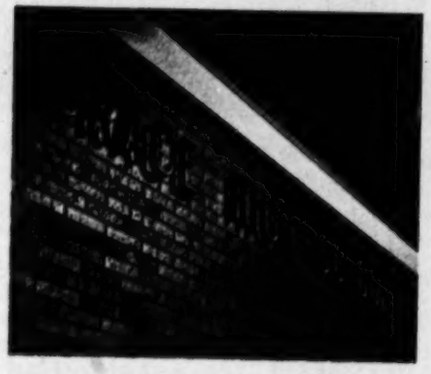
Gas produces all the energy this high school needs (including electricity) at a projected savings of $11,639 a year.*

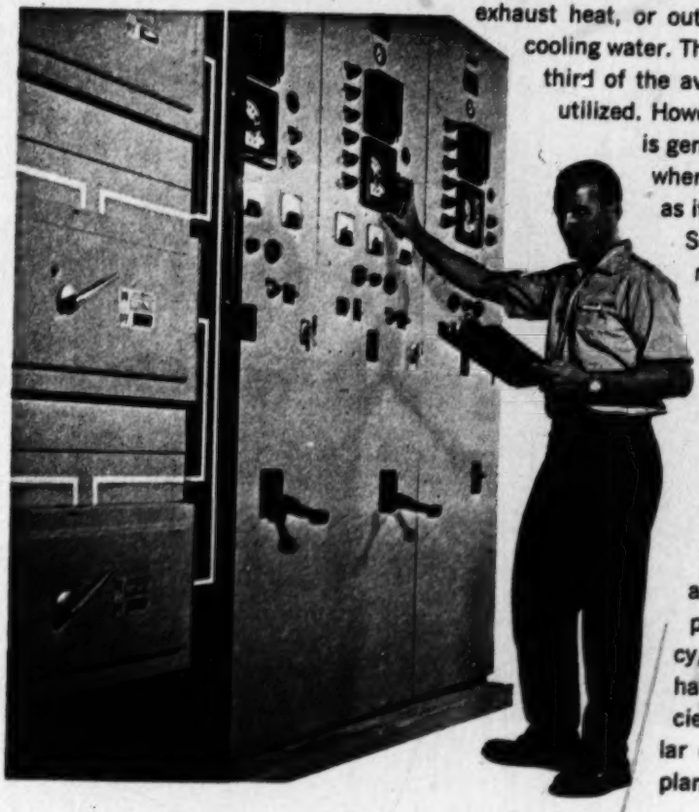
Hard to believe? It's true. In its first year of operation, the gas total energy plant in use at Grace High School in the Minneapolis area is expected to save the institution over $11,600. And



the reliability has been outstanding, too. Students haven't missed a single day of classes due to power failure of any sort.

But, just what is a gas total energy system? It's a method of power production based upon on-site generation with natural gas provided by Minneapolis Gas Company as the fuel. At the heart of Grace High School's system are three gas reciprocating engine-generator sets, any two of which can provide all of the electricity needed in the school. (Approximately 350 kilowatts per hour peak load during school hours.) Exhaust and engine-jacket water heat from the engines is captured by a 110-ton absorption unit and a heat exchanger to produce the energy used to heat and cool the 151,000 square-foot complex, as well as heat the domestic hot water.

Herein lies the economy secret of the gas total energy system. In a central electrical power plant, more than 60 per cent of the fuel's potential energy is wasted—up the stack with the exhaust heat, or out with the engine cooling water. Therefore, only one third of the available energy is utilized. However, when power is generated at the site where it is to be used, as it is at Grace High School, the energy not converted into electricity is captured to meet the operation's thermal needs: heating and cooling. Grace High School's total energy system operates at approximately 80 per cent efficiency, or two-and-one-half times the efficiency of the regular electrical power plant.



1192

What does this increased efficiency mean to Grace High School? Simple: Money.

*Projected Purchased Powsr Costs, School Year, 1966-67 (Gas and Electricity)	$26,391.00
*Projected Total Energy Operating Costs, 1966-67 (Including Maintenance Overhaul Allowance)	14,752.00
Total Operating Savings, 1966-67	$11,639.00

In addition to the $11,600 in projected operating savings this year, the school realized an additional savings in that they didn't need to purchase expensive standby power equipment. Furthermore, the system also made it possible to enclose the building substantially, thereby eliminating perimeter walls and, thus, saving a considerable amount on construction costs. When asked how he felt about the gas total energy system at Grace High School, Building Maintenance Superintendent Brother Donald said the system was ". . . economical and efficient, and operates with a minimum amount of maintenance and supervision."

Gas total energy systems are currently saving money for more than 350 installations like Grace High School all across the country. One can do the same for you in your operation. For more information, just drop us a line. You'll be very glad you did.

For information, current publications, or a preliminary study on the feasibility of a gas total energy system in your operation, simply write: Sales Promotion Department, Northern Natural Gas Company, 2223 Dodge Street, Omaha, Nebraska 68102. Of course you're under no obligation.

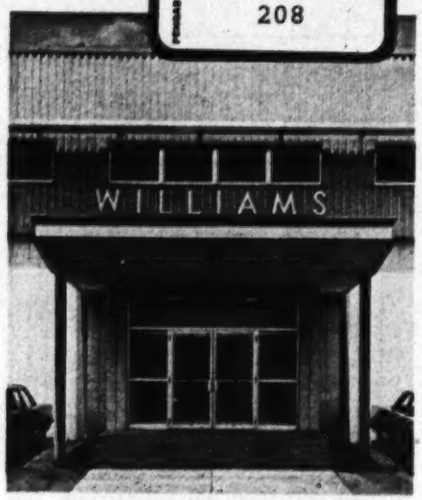
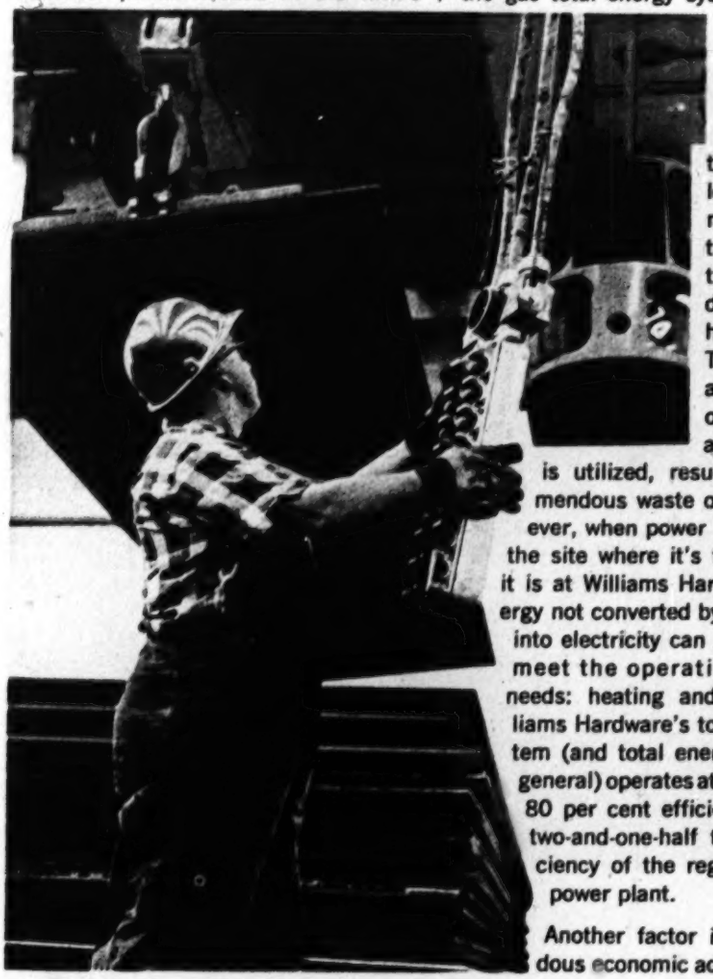
Williams Hardware buys all of its electricity from the gas company. And saves $14,000 a year in the bargain.

Impossible? Not at all. Williams Hardware, in Minneapolis, has not one, but two, gas total energy systems. (One with three engines and the other with two engines.) And in their second year of operation, they saved Williams more than $14,000 in purchased power costs, not to mention the money saved when power outages would have otherwise forced shutdowns.

But, just what is a gas total energy system? It's a method of power production based upon on-site generation with natural gas as the fuel. At the heart of Williams Hardware's total energy systems are five gas reciprocating engine-generator sets, which supply all of the electrical power needed in the firm's offices, hardware warehouse, and massive steel warehouse combined (a total of more than 1,200,000 kilowatts a year). Then, exhaust and engine-jacket water heat from the engines is captured by a heat exchanger to produce the energy needed to cool the offices and hardware warehouse (through a 50-ton steam absorption unit), and to heat the entire 178,000 square-foot complex as well. (A completely modern complex housing not only a vast stock of sheet steel and rolled bars, but cranes, shears, press brakes, saws, flame cutting equipment, and surface grinders as well.)

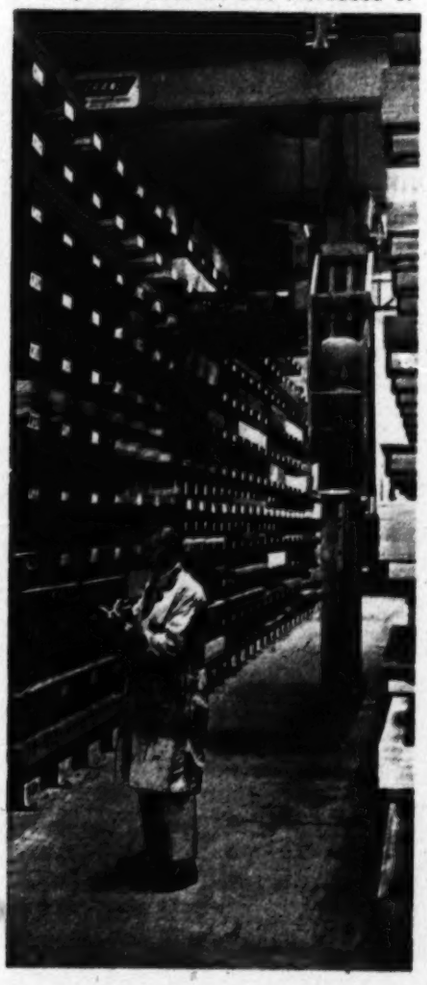


Herein lies the economy secret of the gas total energy system. In a central electrical power plant, more than 60 per cent of the fuel's potential energy is lost to the atmosphere — up the stack with the exhaust or discharged as heat to water. Therefore, only about one-third of the fuel's available energy is utilized, resulting in a tremendous waste of energy. However, when power is generated at the site where it's to be used, as it is at Williams Hardware, the energy not converted by the generator into electricity can be captured to meet the operation's thermal needs: heating and cooling. Williams Hardware's total energy system (and total energy systems in general) operates at approximately 80 per cent efficiency, or about two-and-one-half times the efficiency of the regular electrical power plant.

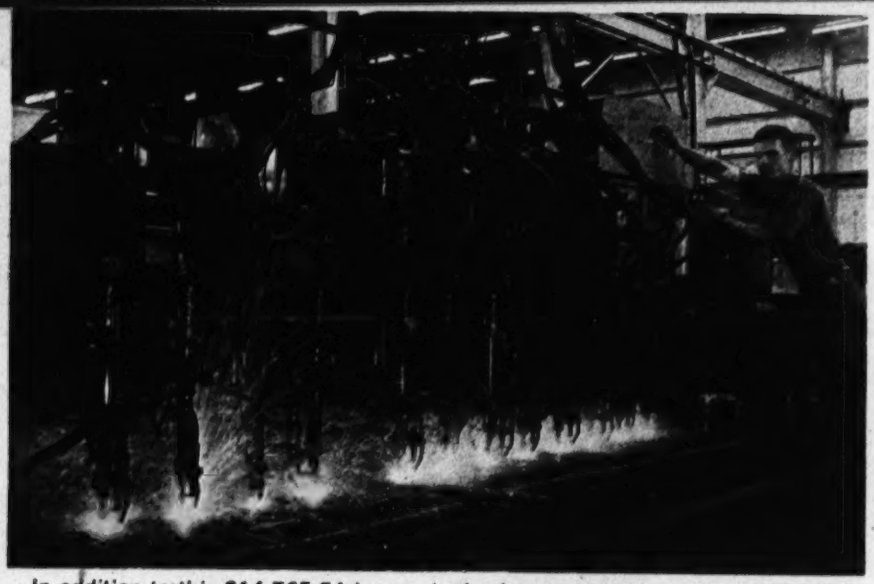


Another factor in the tremendous economic advantage of the gas total energy system over the regular electrical power plant is the fact that a gas total energy system is by far the more reliable of the two. For instance, since Williams generates all the electrical power they need right in their own plant, power outages due to weather disturbances have been virtually eliminated. Therefore, so have work stoppages resulting from these power failures.

But, what does all this increased ef-



1194



ficiency and reliability really mean to Williams? The same thing it would mean to you in your operation: Money!

Estimated Purchased Power Costs (1,200,000 kws) 5/8/67—5/8/68	$22,889.30
Purchased Gas Costs (Equiv. 1,200,000 kws.) 5/8/67—5/8/68	8,123.76
*Total Operating Savings 5/8/67—5/8/68	$14,765.54

In addition to this $14,765.54 in operating savings over a year's time, Williams also realized an additional savings of considerable size in that they didn't need to purchase expensive standby power equipment. You see, a gas total energy system virtually acts as its own standby. But is Williams Hardware really pleased with the performance of their two gas total energy systems? Well, according to Jack Ocenasek, warehouse superintendent, they're so pleased they're currently planning the installation of their sixth gas engine later this year so they can save even more money.

Gas total energy systems are currently saving money for more than 450 installations like Williams Hardware all across the country. One can do the same for you in your operation, whatever your operation is. So, if you're really interested in cutting down your cost of doing business (And who isn't?), look into a gas total energy system today. For more information, current publications, or a preliminary feasibility study, just write: Sales Promotion Department, Northern Natural Gas Company, 2223 Dodge Street, Omaha, Nebraska 68102. Of course, you're under no obligation.

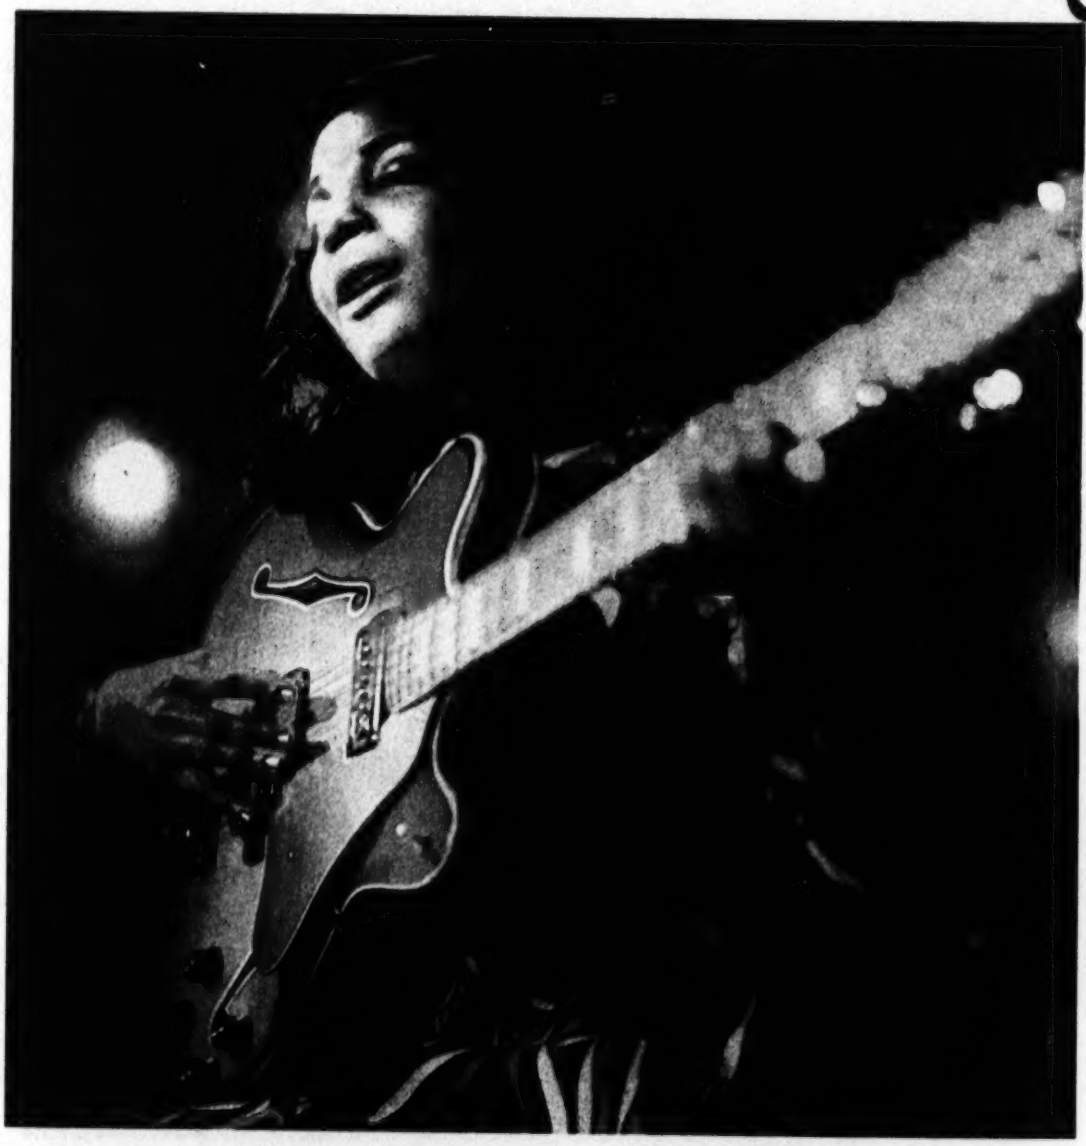
Northern Natural Gas Company

Home Office: Omaha, Nebraska

*These figures do not include maintenance costs on the total energy systems, which Williams feels are more than offset by heat-recovery savings resulting from the use of the total energy equipment.

1195

DEFENDANT'S EXHIBIT 209



Introducing the gas guitar.

The switch to Gas Total Energy is on.

No. It's not a joke. The electricity to power the guitar, and the psychedelic lights, and the juke box, and all the other exciting effects and practical appliances in many a night club comes from a natural gas total energy system, and not from a distant power station.

Why gas total energy? Because the owners and investors who build theaters, music halls, galleries and sporting arenas know that a gas total energy system will make their buildings all but self-sustaining. And at annual operating cost savings unheard of 10 years ago.

Total energy systems powered by gas generate electricity and utilize recovered heat on the site where the energy is going to be used. This means ultra-reliable electric power for lighting, motors, appliances . . . yes, even guitars. Heat recovered from the natural gas prime movers provide energy for space heating and cooling, water heating and industrial processing. The natural gas supply, which is the sole source of energy, is also available for cooking and other applications. Total energy systems operate at maximum efficiency, need little maintenance and act as their own standby power supply.

Sold on gas total energy? If not, you soon will be. For complete details contact your local gas company, or Bob McChane, Sales Promotion Department, Northern Natural Gas Company.

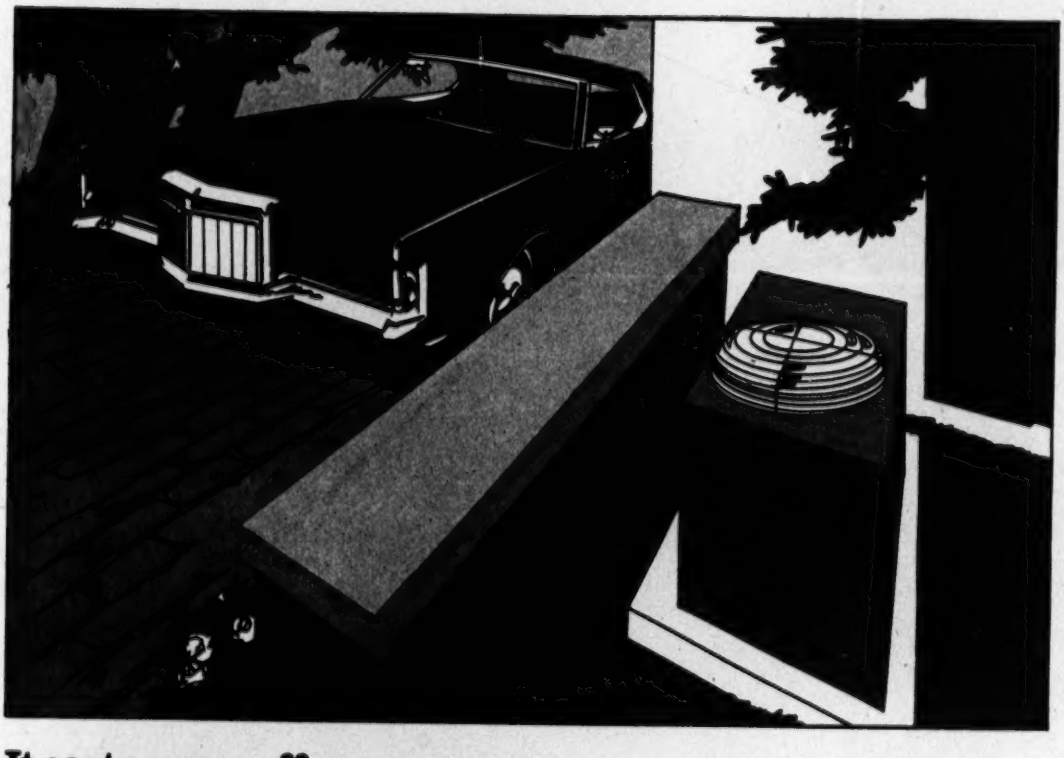
Gas air conditioning is like a car that's better than good.

DEFENDANT'S EXHIBIT 210



It costs more; offers more; runs more efficiently; gives you more day-to-day satisfaction; and, in the long run, saves you a pile of money on maintenance and operating costs. Sound good? Read on:

A gas air conditioning system is what you buy when you want something very special for the long haul.

More expensive? Sure. But it pays off every time it goes on.

It's cool, it's quiet, it's dependable—no matter how hot and humid the weather.

When other units grind and grunt, a gas unit purrs. There are no major moving parts to go wrong, fewer reasons to call in a serviceman.

If a major component (chiller, coil or control) should act up anytime *within two years*, Northern Illinois Gas will send a man out to fix it free... no charge for parts and labor. You save on operating costs, too. In fact, when you compare longer life and operating savings with electric, the higher initial cost of gas air conditioning disappears.

You pay nothing down and can take as much as five years to pay for your complete installation. Northern Illinois Gas can arrange the financing for you.

Interested? Get in touch with your gas air conditioning equipment contractor. Or call us.

We call it the Patio Pair...by Charmglow

Now it's party-time in no time at all! A modern gas grill turns on delicious charcoal taste instantly with a simple turn of the dial. Lets you cook with controlled heat . . . with even heat . . . without charcoal mess or bother.

And to put more lovely light on the party, the perfect patio companion is an elegant gaslight. Casts its soft warm light over your party with a flair that says, "you're welcome here." Yet guards your house against prowlers when the party's over.

Whether your next party be for birthdays or for entertaining...for the whole family or just for the two of you, turn it on instantly with a gas grill and companion patio gaslight.

Your family will call it a blessing. We call it the patio pair. How do you get yours? Call one of these near-by dealers now.

Now. The gas self-cleaning oven. For builders who like to build sales. Period.

Self-cleaning gas ranges by Magic Chef.

It's the biggest, wildest, most exciting Gas Industry promotion ever. Period.

Cash in on the massive advertising attack, and build around it. Because *this* is the year of the *gas* self-cleaning oven.

Your home-building and home-remodelling prospects will be seeing it on television. And reading about it in Life and other national magazines. And being exposed to it almost everywhere appliances are sold.

This all-out promotion will announce that the gas self-cleaning range is fast, cool, and economical. It's available in slide-in, free-standing and eye-level models —30 and 36 inch widths—all colors. Remember that more of your customers prefer gas to begin with—and now that gas has a self-cleaning oven, more and more people will be joining the ranks. How about you? See your Gas Company for details.

Texas Gas invites you to the wireless house.

The wind may blow, the rains may fall, and the thermometer may have a nervous breakdown. But the wireless house runs along, quiet and calm, making its own heat and light, cool and climate as the seasons demand.

This is the house of tomorrow. No electric power lines subject to the whims of nature. The energy comes pure and quiet from one slim buried tube of natural gas. The gas heats and cools the house.

And some of the gas is converted into a new, super active form of natural gas called "Reformed Natural." This reformed natural gas runs all major appliances in the wireless house. It also operates a fuel cell that generates electricity.

Even though it may be some years before this environmental house is available on the market, it's just one more result of the restless gas technology that keeps our pipeline business growing steadily year after year.

And gas is only half of it. Texas Gas is a prime mover on the booming inland waterways, with our American Commercial Barge Line and our Jeffboat shipyard.

We're moving on the highways with two strong interstate trucking enterprises, Terminal Transport and Commercial Carriers.

We're also moving into the inland offshore oil and gas business through Crestwood Offshore Services.

And we're active in oil and gas exploration and production through our Texas Gas Exploration Corporation.

The fact is, while very few people were looking, Texas Gas moved all the way up into the top 100 U.S. Corporations.

Maybe it's time you took a closer look at Texas Gas. Write to: Texas Gas Transmission Corporation, Owensboro, Ky. 42301. We'll send you our Annual Report.

TXG

Texas Gas Transmission Corporation · American Commercial Barge Line Company · Jeffboat, Incorporated · Terminal Transport Company, Incorporated · Commercial Carriers, Incorporated · Rowan Dredging Company, Incorporated · Crestwood Offshore Services, Incorporated · Texas Gas Exploration Corporation

Here's the story of the Gas fuel cell.

DEFENDANT'S EXHIBIT 214

Imagine a small cabinet-size unit in your home that produces all the electricity you need.

Now you can stop imagining. Because silent, efficient Gas fuel cells have already proved themselves in thousands of hours of operation. These incredible units are actually the same in principle as the ones that have powered American spacecraft.

There's so much faith in the fuel cell that a group of Gas industry companies is investing more than $20 million in research and development. Successful research will result in moving the Gas fuel cell from prototypes to production models, and a major industry will be built.

The research investment is based on a simple fact: the most economical way to produce energy is to convert piped Gas at the point of use. And this is true for Gas heating, Gas cooling and "Gas electricity."

But is this really so surprising? After all, Gas is almost pure energy.

AMERICAN GAS ASSOCIATION, INC.

NUCLEAR STEAM-GENERATION OF ELECTRICITY: ITS IMPLICATIONS FOR THE FUTURE OF COAL TRANSPORT BY RAILWAY AND WATERWAY

JOHN C. SPYCHALSKI

Few commodities can match the longevity and significance of coal's contribution to the traffic and revenues of railways and water carriers. The primeval railways—or tramways—of Elizabethan England were contrived as a means for linking land-locked coal mines with navigable waterways.[1] Many of the railways and canals constructed on both sides of the Atlantic during what could be characterized as the dawn of the modern era in transport—1800-1835—counted coal as their single most important traffic item.[2] A century later, in 1928, the first year for which American railway freight tonnages and revenues were reported by commodity groups, coal ranked second as a source of both railway carloadings and revenues. It was exceeded only by the merchandise and miscellaneous groups, which encompass a multitude of heterogeneous finished and semi-finished manufactured goods not individually reported.[3]

But, changing technology and rival fuels challenged coal's dominance as a source of energy after 1930. Oil and natural gas virtually eliminated coal in the locomotive and maritime fuel markets and reduced coal's use (measured in tons) for residential and commercial heating by approximately 85 percent between 1945 and 1965.[4] Coal sales to firms in the manufacturing and mining industries suffered declines of lesser magnitude during the same time period.[5]

These events held potentially negative consequences for the principal modes of coal transport. Nevertheless, rising sales of coal to the electric

[5] Ibid.

utility industry[6] and to foreign buyers together with motor transport's capture of much actual and potential railway traffic in finished and semi-finished goods preserved coal's rank as a contributor to railway carloadings and revenues. Coal presently accounts for approximately 19 percent of total carloadings and produces about 12½ percent of all railway freight revenues.[7]

The maintenance of this rank has been achieved in the face of competition from new substitutes for the rail movement of utility steam coal.[8] Water carriage—limited, of course, to transport markets served by navigable waterways—represented the only alternative for large-volume, longer-distance coal movements until 1957, when a 108-mile pipeline carrying coal in slurry form was placed in operation between a mine at Cadiz, Ohio, and a generating station in Cleveland. Its subsequent technological and economic success sparked proposals to serve other coal transport markets with slurry pipelines. The late 1950's also saw technological advances in the long-distance transmission of high-voltage electricity. These advances increased the economic feasibility of substituting the conduction of electricity produced at locations proximate to coal deposits for the long-distance haulage of coal. The railways effectively countered the slurry pipelines—and, to a lesser extent, mine-mouth generating stations—with rate reductions based on (1) lower profit margins and (2) decreases in coal movement costs achieved through such innovations as unit trains and larger-capacity rolling stock.[9]

Coal has represented about 23 percent of the total net tons of all commodities carried by inland waterway (exclusive of the Great Lakes) since 1960.[10] In absolute terms, total inland waterway coal traffic increased from 65.9 million tons in 1958 to 86 million tons in 1964. Electric utility steam coal's share of this tonnage increased from approximately 50 percent in 1958 to 58 percent in 1964.[11]

Coal traffic on the Great Lakes rose from 40.2 million tons in 1958 to 51.3 million tons in 1964, but the portion of this traffic destined for electric utilities fell from approximately 58 percent in 1958 to 40 percent in 1964.[12] Coastal shipping and motor carriage also participate in the movement of utility steam coal, but in amounts substantially below those hauled by railway and inland waterway.[13]

[13] Ibid.

The Atom Enters

Even as railway corporate strategists were drawing measurable success from their counterattack against coal slurry pipelines and high voltage long distance electricity transmission, they, together with coal-hauling water carriers, moved toward a confrontation with the spectre of nuclear steam-generation of electricity.

During the early 1960's, nuclear power's potential economic advantage appeared promising but far from realization. Coal's continued domination of the present and near-term future of steam electricity generation seemed secure. The economies of coal-fired generating technology in its most advanced stages were generally considered to be markedly superior to anything that nuclear power could muster.[14] But suddenly—more so than even some of those closely associated with the development of nuclear steam electricity generation had predicted—the atom overtook coal. Nuclear energy's share of total electricity generating capacity ordered new jumped from 10 percent in 1965 to over 50 percent in 1966.[15] This abrupt triumph resulted from various technological advances which, taken collectively, occasioned significant reductions in both the capital and operating costs of nuclear steam power plants.

An indication of the magnitude of these reductions is provided by the fact that nuclear power stations now on order or under construction are expected to produce electricity at costs ranging downward from 3.68 mills per kilowatt hour.[16] This estimation includes allocations for depreciation and interest expenses.[17] By contrast, nuclear stations placed in operation during the early 1960's produced power at cost levels ranging from 4.00 mills per kilowatt hour to 9.37 mills per kilowatt hour *exclusive* of depreciation and interest expenses.[18]

Operating costs of privately- and publicly-owned coal-fired generating stations in service in the United States during 1965 ranged from below 2.5 mills per kilowatt hour to above 5.51 mills per kilowatt hour. The operating costs of some of these plants exceeded 10 mills per kilowatt hour (see Tables 1 and 2). These cost data include labor, fuel, and maintenance expenses but exclude allowances for depreciation, interest, and administration.

Some means for comparing the capital costs of coal-fired plants with those of nuclear-fired installations can be obtained by an inspection

---

[14] William Webster, "The Commercial Future of Nuclear Power," Edison Electric Institute Bulletin, Vol. 34, No. 9 (October, 1966), Section I, p. 328.

[15] Barron's November 7, 1966, p. 5; and The Wall Street Journal, March 15, 1967, p. 32.

[16] Public Utilities Fortnightly, February 2, 1967, p. 59.

[17] And thus is dependent on certain assumptions concerning estimation of the plants' useful life and the division of costs incurred during construction between capital and expense accounts.

[18] Steam-Electric Plant Construction Cost and Annual Production Expenses, Eighteenth Annual Supplement, 1965, (Washington, D.C.: Federal Power Commission, 1966), pp. 157-161.

of the investment per kilowatt of installed capacity for each type of plant. Capital costs for nuclear plants presently range from about $175 per kilowatt of installed capacity for plants of 300,000 kilowatts capacity to between $120 and $110 per kilowatt of installed capacity for 1,200,000 kilowatt plants.[19] As Table 1 indicates, the capital costs of coal-fired stations appear to be less than those for nuclear plants in the 275,000-300,000 kilowatt capacity range. However, nuclear capital costs lie below those of coal for larger-sized installations.

A dramatic manifestation of nuclear energy's apparent economic triumph over coal in relatively large generating installations occurred during the summer of 1966, when the Tennessee Valley Authority ordered a 2,196,000 kilowatt capacity nuclear-fueled power station. The Authority estimated that this plant would produce electricity at a total cost of 2.39 mills per kilowatt hour, 18 percent lower than the estimated cost of a new coal-fired facility of equivalent capacity. Moreover, the Authority's nuclear station will be located virtually atop low cost steam-coal deposits.[20]

Table I. Plant Capital Costs and Annual Production Expenses for Selected Coal-Fired Generating Stations, 1965 [1]

Name of Owning Utility and Plant	Plant Capacity (kilowatts)	Plant Investment Cost per Kilowatt Hour of Installed Capacity (dollars)	Total Production Expenses (mills per kilowatt hr.) [2]	Initial Year of Plant Operation

The Outlook for Utility Steam-Coal Transport

With these events in hand, what course can be plotted for the future of utility steam-coal carriage? The Tennessee Valley Authority's decision to locate a nuclear-fueled facility proximate to steam-coal deposits [21] is a potent thrust in support of the view that nuclear power can compete successfully with coal in virtually any geographic location. Nuclear power's ability to permanently retain this advantage will depend on the future trend of its operating and capital costs vis-à-vis those of coal-fired plants, and the atom's prospects seem to be relatively more favorable.

Available evidence indicates the likelihood of a long-run downtrend in the operating costs of boiling-water and pressurized-water type reactors now in service and on order.[22] Fuel costs for these plants, presently about 1.8-2.0 mills per kilowatt hour, are expected to decline below 1.2 mills per kilowatt hour by 1980 as a result of (1) successive reductions in the costs of fabricating and reprocessing nuclear fuel; (2) reductions in the length of time required for replacement of a reactor's "spent" fuel core; and (3) the design and manufacture of more efficient fuel cores capable of being used in reactors of present vintage.[23] Even lower fuel costs appear attainable when and if one or several of a variety of more sophisticated types of reactors presently in planning and experimental stages become operationally feasible from both a technological and an economic standpoint.[24]

Nuclear power generation costs might be reduced in some geographic locations through joint-use applications.[25] For example, a group of Southern California utilities are presently negotiating an agreement to build a nuclear desalination plant that will also produce electricity for distribution through their systems.[25]

Nuclear generating units of existent design promise marked economies of scale. For example, the Commonwealth Edison Company's Dresden No. 2 nuclear plant, ordered in 1965, is only 20 percent larger than the same firm's first atomic plant, Dresden No. 1, which began operating in 1960. Yet, Dresden No. 2 is expected to produce four times as much electricity as Dresden No. 1 is capable of producing at half the cost of

---

[21] It appears that the Authority is not yet firmly convinced that nuclear power has established a permanent economic advantage over coal. The Authority has since ordered a second nuclear-powered station, but the contract for it includes a cancellation clause that can be exercised if the tide of energy cost economies should turn back toward coal. (Business Week, January 28, 1967, p. 89).

[22] An exposition of the design, construction, and operation of nuclear generating units lies beyond the purpose of this paper. For treatments of these topics, see, e.g.: Public Utilities Fortnightly, February 2, 1967, op. cit.; William Webster, op. cit.; and Fortune, op. cit.

[25] The Wall Street Journal, March 10, 1967, p. 4.

Dresden No. 1.[26] Such economies will complement recent technological innovations which have greatly reduced the costs of long-distance high voltage power transmission.

Non-nuclear steam-electric power production costs per kilowatt hour fell 10.44 percent between 1956 and 1965,[27] but this decline leveled off markedly during 1966 because "(c)ost reductions related to the continuing increase in the size and efficiency of generating units and delivered fuel cost no longer dominate the cost pattern."[28]

This appraisal applies to gas- and oil-fired units as well as to coal-fired stations, but evidence exists which suggests that a separate evaluation for coal would not produce a different answer. Significant reductions in fuel costs, which comprise between 75 and 80 percent of the average coal-fired station's total annual operating costs (exclusive of depreciation and interest)[29] appear improbable. Coal's f.o.b. mine prices for sales to large-volume buyers have remained relatively stable since 1950,[30] and coal industry executives see little chance for reducing the price of their product.[31] The delivered price of coal has been lowered in recent years through coal freight rate reductions,[32] but there are signs that no margin exists for further reductions. In fact, some carriers recently increased rates on utility coal moved in trainload lots—movements for which charges had been drastically reduced relative to charges for single-car consignments during the early 1960's.[33] Coal's use-cost will also be increased by utilities' accedence to recent demands for adjustments designed to reduce the amount of air-polluting fly ash and sulfur dioxide spewed from power station smokestacks.[34]

The future course of total costs per kilowatt-hour for coal-fueled generating stations cannot be predicted in terms of meaningful quantities. However, there is no evidence of the existence of conditions capable of occasioning scale economies in coal-fired installations that approach the magnitude of those identified with nuclear plants.

The foregoing observations together with repeated upward revisions of estimated future nuclear generating capacity and the achievement of new highs in terms of the atom's share of generating capacity ordered during the closing months of 1966 and the opening months of 1967[35] suggest that further increases in the total demand for utility steam coal will be limited. Furthermore, most of the recently-ordered coal-fired

generating stations will either be located near mine-mouths or linked to mines by slurry pipelines.[28] Thus, total demand for the (non-pipeline) transport of utility steam coal seemingly stands little if any chance of achieving further substantial growth.

Continuance of the present indicated relationship between operating and capital cost levels in nuclear and coal-fueled steam generating stations appears highly probable and would dictate that coal concede its utility steam generation market to the atom over the long run. This implies the emergence of a corresponding pattern of long-run declining demand for the transport of coal to existing coal-fired generating stations. Thus, private and public decision makers concerned with the performance of transport firms heavily dependent on utility steam coal traffic appear to be confronted by two primary considerations: (1) The rates at which existing utility steam coal transport markets will decline; and (2) The formulation and execution of policies designed to mitigate adverse effects of the loss of utility steam coal traffic.

Determinants of the Rates of Decline in Existing Utility Steam Coal Transport Markets

The future pattern of utility steam coal traffic will be determined fundamentally by the relationship between the costs of continuing to operate existing coal-fueled generating capacity and the costs of replacing it with nuclear installations. Abstracting for the moment from other influences on the replacement of coal by the atom, which will be discussed later, this means that the susceptibility to loss (in terms of time) of particular coal traffic movements will be a function of the level of operating costs of the plant to which the coal is delivered.

An assessment of such susceptibility for individual coal transport markets lies beyond the bounds of this paper. However, a suggestive indication of the susceptibility of the total utility steam coal transport market to loss through nuclear substitution can be obtained by comparing utility coal consumption data classified by power plant operating cost ranges with nuclear power plant operating cost data. Thus, a comparison of data presented in Table 2 with the previously-noted fact that nuclear power plants now on order are expected to produce power at estimated costs (including depreciation and interest) below 2.50 mills per kilowatt hour suggests that, of the total potential 1965 utility steam coal transport market, 66.6 million tons, or approximately 27 percent, could be characterized as immediately susceptible to loss, 97.1 million tons, approximately 40 percent, could be characterized as vulnerable to loss within an intermediate-term time period, and 55.5 million tons, approximately 23 percent, could be viewed as relatively immune to loss over the remaining physical lives of the plants in which it is burned.

[2] Excludes interest, depreciation, taxes, and certain administrative expenses.

These data, the most recent available, must be used with the caveat that they (1) are unadjusted for privately-transported coal and coal which does not require long-distance movement by virtue of its consumption in mine-mouth power stations [37] and (2) represent only 219.2 million of the total 244.9 million tons of coal burned in steam generating stations during 1965.[38] The 25.6 million ton shortfall represents (a) coal burned in plants for which either incomplete or no operating data were reported to the Federal Power Commission and (b) coal consumed in plants producing both steam and electricity for sale.[39]

The rate of growth in the demand for electricity is another determinant of the pace at which coal-fired generating stations will be phased out in favor of nuclear plants. Questions can be raised about if and when capacity for supplying reactor equipment and/or nuclear fuel will be sufficient to fulfill demands for both new generating capacity and the replacement of existing capacity. These topics cannot be probed in depth here. However, it seems conceivable that the complementary relationship between long-distance high voltage electricity transmission and the scale economies of large-capacity nuclear generating plants could permit (to some degree, at least) the simultaneous replacement of smaller-capacity coal-fired stations and the addition of new generating capacity. Also, evidence exists that any bottlenecks which might arise in the supply of nuclear generating equipment and fuel will probably be of short- to intermediate time-length rather than of long-run duration.[40]

This raises the question of whether utility regulatory authorities would permit a level of earnings on new, technologically-advanced assets sufficient to sustain continuing financial obligations on retired, eco-

[37] Most of which rank high in terms of operating efficiency.

[39] Ibid.

[40] The Wall Street Journal, January 5, 1967, p. 30; and Ibid., March 15, 1967, p. 32.

nomically obsolete assets. The point at issue here is whether financial losses occasioned by economic obsolescence can and/or should be borne completely by utility common stockholders, by users of electricity, or shared on a proportional basis by these two groups.[41] If faced with the first-mentioned alternative, utility managers might be inclined to "run-out" coal-fired plants until their undepreciated balances fall very low.

One could also ask whether utility managements would retire economically obsolete but physically undepreciated coal-fired plants in the absence of financing-regulatory barriers. Some writers[42] contend that utility companies exhibit a meager propensity for making cost-cutting innovations because of (1) the relatively assured demand for electricity and (2) suggestions that commission-administered controls over utility earnings contain no provisions for rewarding those utility firms which alacritously pursue more efficient methods.[43] But, evidence exists that at least some utilities aggressively seek out ways for reducing their operating costs.[44]

Policies to Mitigate Effects of the Decline in Utility Steam Coal Traffic

Water Transport

Evidence of the movement value of inland waterway coal traffic is unavailable (see footnotes 10, 11, and 12, supra), and coal tonnage data are not reported separately for either the private and for-hire sectors of inland water carriage or the firms within each category. Nevertheless, data presented in Table 3 are sufficient to suggest that the loss of utility steam coal traffic could hold significant consequences for firms operating on certain waterways. Such losses will, however, probably tend to be concentrated over a relatively long-run time period,[45] because an inspection of the operating costs of waterside coal-fueled power stations[46] suggests that many of these plants lie in that range described previously in this paper as "relatively immune" to replacement by nuclear power before the end of their expected physical life. Thus, there appears to be little likelihood that the value of existing floating equipment dedicated to coal haulage—and for which no alternative employment

---

[41] This article takes no position on the problem. It is posed because policies designed to resolve it will affect the demand for utility steam coal transport service.

[46] Steam-Electric Plant Construction Cost and Annual Production Expenses, Eighteenth Annual Supplement, 1965, op. cit., pp. 1-161.

of equivalent profitability can be found—will fall victim to nuclear power."[47]

But, this condition should not be interpreted as freeing water carrier executives of their responsibility for basing investments in new coal-hauling equipment on (1) carefully-researched estimates of the longevity of their existing utility steam coal transport markets and (2) identification of the availability of alternative uses for barges and towboats dedicated to coal haulage. Those coal-dependent carriers which desire a corporate life extending beyond the existence of their utility coal transport markets must intensify efforts to develop traffic in other commodities.

Great Lakes-borne coal is moved in part by vessels which also carry other bulk commodities. Some lake ships see only coal-hauling service, but their age is such that they can probably serve out the duration of the Great Lakes' utility steam coal transport markets without replacement. They have already been depreciated to the point where an early collapse of those markets would not result in significant capital losses.[48]

Nuclear power's influence on utility steam coal traffic should also be considered in public investment decisions concerning both the improvement of existing waterways and the construction of new navigation routes. Some navigation projects currently in planning and construction stages[49] are intended for locations where a substantial volume of coal tonnage either presently moves (see Table 3) or is expected to move. Benefits-cost analyses of these projects should therefore be carefully scrutinized in an effort to prevent investments in situations where it appears that coal tonnage will not endure in amounts and time-periods sufficient to permit the realization of benefits in excess of costs.[50]

Railway Transport

The loss of railway utility steam coal traffic will most acutely affect carriers in the Eastern and Southern Regions, where coal accounted for 32 percent and 19 percent respectively of total revenue carloadings in 1965.[51] Table 4 indicates the extent to which individual carriers in these areas depend on coal traffic. A precise breakdown of the proportion represented by utility steam coal (as distinguished from coal destined for other uses) is unavailable, but, as noted previously, utility steam

[2] Includes tonnage hauled by both private and for-hire carriers.

coal represents between 55 and 65 percent of all coal tonnage moved by the railway system as a whole. A crude indication of the value which this traffic represents can be obtained by observing that 55 to 65 percent of total railway coal revenues ranged from $182.4 million to $215.5 million, respectively, in 1963.[22]

Accurate measurements of railway coal traffic's relative profitability are virtually impossible to obtain. The Interstate Commerce Commission's Bureau of Accounts estimates that total coal traffic revenues amount to 108 percent of the out-of-pocket costs occasioned by coal movements.[23]

---

[22] Bituminous Coal Facts, op. cit., p. 99.
[23] Interstate Commerce Commission, Bureau of Accounts, Distribution of the Rail Revenue Contribution by Commodity Groups—1961, Statement No. 6-64, Washington, D.C., June 1964, p. 41. The bounds of this paper preclude an in-depth critique of the Commission's estimation procedures. However, it should be noted that the percentages presented here are products of gross averaging which, among other shortcomings, does not reflect the fact that rail unit costs and revenues on each type of commodity hauled differ with variations in traffic density and operating costs over specific segments of rail line. Thus, the Commission's estimates may be either higher or lower than the relationships actually realized on specific carload journeys produced by particular railway companies between given pairs of origin and destination points. The statistical representativeness of the Commission's estimates can also be questioned, because the Commission employs revenue data obtained from its one percent waybill sample.

Table 4. Bituminous Coal Revenues as a Percentage of Total Freight Revenues, and Bituminous Coal Carloadings as a Percentage of Total Carloadings, for Selected Railway Companies in the Most Recent Years of Data Availability.[1]

Railway Company	Year	Bituminous Coal Revenues as a Percentage of Total Freight Revenues	Bituminous Coal Carloadings as a Percentage of Total Carloadings
Chesapeake and Ohio	1965	47.2	46.4
Baltimore and Ohio	1965	25.4	33.3

[1] Source: Moody's Transportation Manual, 1966.
[2] Includes results for Wabash Railroad, Pittsburgh & West Virginia Railway, Wheeling and Lake Erie Railway, and the former New York, Chicago and St. Louis Railroad. The operations of these companies were combined with those of the Norfolk and Western by either lease or merger on October 16, 1964.

Several of the coal-dependent roads named in Table 4 enjoy strong (for the railway industry) rates of return, while the financial stamina of others can be characterized as modest during relatively high levels of general economic activity and precarious during recessional periods. However, some of the relatively strong roads are among those most dependent on coal traffic and revenues and should therefore not necessarily be viewed as the companies most likely to emerge from a permanent decline in coal traffic with their relative strength intact.

It should also be noted that most of the coal-fueled generating stations described previously in this paper as "most susceptible to nuclear conversion" or "susceptible within an intermediate time period" are rail-served.[84]

The foregoing observations emphasize the need for early recognition of, and action to cope with, the threat which nuclear power poses to coal traffic's future. Railway companies must intensify their efforts in the areas of market research, equipment design, and cost-pricing-profit

[84] Based on an inspection of information presented in Steam-Electric Plant Construction Cost and Annual Production Expenses, Eighteenth Annual Supplement, 1965, op. cit.

analysis to (1) identify potential new traffic in non-coal commodities and (2) define and provide the service-price combinations required to profitably realize that traffic. The achievement of needed cost-price and service-quality levels may, in some cases, require radical departures from conventional operating patterns.[85] Such departures would require aquiescence to work-rule changes by labor organizations representing railway operating employees.

Railway investments in new coal-hauling assets—which continue to be made in substantial amounts at the present time [86]—must be based on rigorous analyses of the specific coal transport markets which they are intended to serve in order to minimize the probability of losses.

Those acquainted with railway traffic flow patterns will recognize that certain segments of line-haul and terminal capacity presently serving utility steam-coal movements cannot be absorbed by other traffic and will therefore have to be withdrawn from service following utility steam-coal traffic's demise. This condition together with the fact that considerable redundancy already exists in portions of the railway plant makes it imperative that barriers to the rationalization of excess capacity be removed if the financial debilitation resulting from utility steam-coal traffic losses is to be minimized. Thus, public and corporate policies that inhibit the consummation of railway mergers designed to eliminate duplicate plant and equipment must be reversed.

Conclusion

Nuclear power will abruptly terminate demand for the transport of utility steam-coal. In fact, such demand will probably rise somewhat in the immediate future. But, it will decline to the point of extinction in the long run if nuclear power maintains its economic advantage over coal-fueled electricity generation. Thus, those responsible for policy-making in carrier board rooms, government chambers, and union lodges should begin now to formulate and execute plans that will permit an orderly transition to dependence on other traffics.

THE CHASE MANHATTAN BANK

New York, New York 10015

DEFENDANT'S EXHIBIT 216

THE PETROLEUM SITUATION

FOR RELEASE: OCTOBER 27, 1969

IN SEPTEMBER, 1969

DEMAND

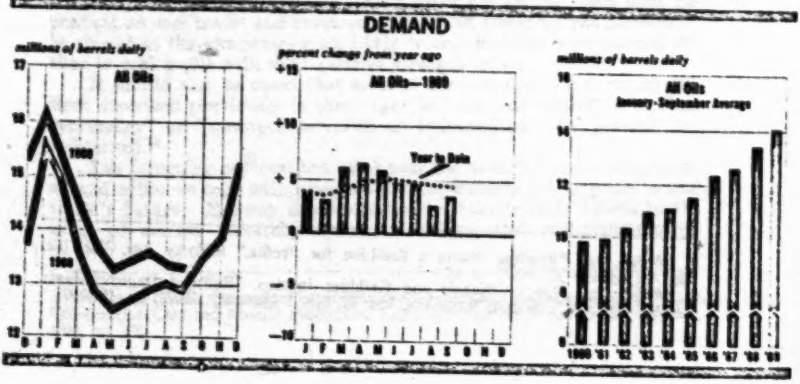
The first three quarters of 1969 have already passed into the record book. It may, accordingly, be useful to look back for a moment and consider how the year has developed. The various measures of fiscal and monetary restraint that were supposed to slow down the rate of economic growth may be starting to take effect at last, but there is little evidence that they produced the desired results earlier in the year. Gross National Product grew at the rate of 7.5 percent a year during the first three quarters of 1969 -- a faster rate of growth than had been anticipated a year earlier.

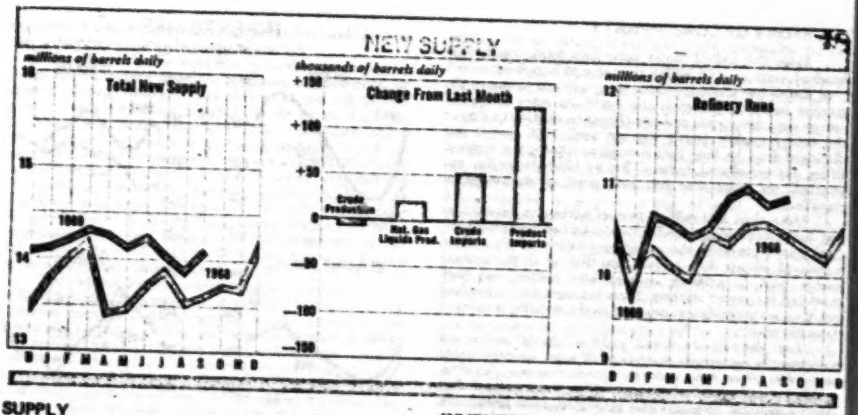
Reflecting the tempo of the economy, the demand for petroleum products also grew faster than expected during the January-September period. The growth amounted to 4½ percent, and this is likely to be sustained over the balance of the year. Not all of the products performed equally well, of course. The middle distillates tended to fall short of earlier expectations, but this was more than offset by the strong demand for gasoline and residual fuel.

The extent to which automotive gasoline demand is dependent upon general business activity is not always fully appreciated. But it should be remembered that trucks and buses account for about one quarter of the total demand and of the amount consumed by passenger cars, 40 percent represents travel to and from work. Accordingly, given the strong economic growth that the nation has experienced this year, it is not surprising that the demand for automotive gasoline during the first three quarters of 1969 registered a 4.8 percent increase over the year earlier period. Demand for aviation gasoline is still dropping, but since this represents less than 2 percent of the total use of gasoline its influence is negligible.

At the outset of the year, very little growth seemed in prospect for residual fuel oil. And yet, by September, the year to date growth for this product amounted to about 5 percent. The particular area of strength is the Electric Utility market on the East Coast, where a combination of circumstances have worked to the advantage of oil. Air pollution regulations have raised serious problems for coal -- the dominant fuel in the Electric Utility market. And an ample supply of low sulphur residual fuel at a competitive price has enabled oil to take full advantage of the situation.

Preliminary figures for the month of September show a 3.5 percent rise in demand for all oils over the level a year ago. Gasoline was the star performer. Demand for this product increased by 7.5 percent and, in fact, accounted for more than four fifths of the total rise in petroleum product demand. The fuel oils fared less well. Distillate lagged behind the year earlier level of demand, and residual fuel showed little change.





SUPPLY

Crude oil production in the United States satisfies two-thirds of the nation's demand for oil. It might be expected, therefore, that crude oil output would grow in line with demand. During the first nine months of 1969, however, there was virtually no change in this source of supply relative to the year earlier period. Alaska and Louisiana posted gains in crude oil production which were largely offset by lower production elsewhere in the nation. Texas, which accounts for a third of the nation's output, produced no more oil in the first three quarters of 1969 than it did in the same period a year earlier.

The other source of domestic raw materials – natural gas liquids – averaged 1.6 million barrels daily and registered a 5.4 percent increase during the first nine months of 1969. Thus, domestic sources provided almost four-fifths of the total new supply of oil during the year to date.

Imports of foreign crude oil during the first three quarters of the year averaged 1.4 million barrels a day, 13.5 percent more than in the same period last year. Half of the increase, however, is accounted for by higher imports of Canadian crude.

In 1968, crude oil shipments from Canada into the area East of the Rockies averaged 300 thousand barrels daily. For 1969, an import ceiling of 306 thousand barrels daily was established by the Department of the Interior and the Canadian government. Because Canadian imports exceeded this limit by almost 40 thousand barrels daily between January and May, the Administration again conferred with Canadian officials and a new understanding was reached stipulating that imports would not exceed the original 306 thousand barrel a day limit from May to the end of this year. Since May, however, Canadian crude imports have averaged 334 thousand barrels a day and in September they reached 385 thousand a day. On the West Coast, Canadian crude imports rose from 164 thousand barrels daily in the first nine months of 1968 to 210 thousand a day this year.

Imports licensed directly by the government are running ahead of the quota established for 1969, but this will have to be corrected during the fourth quarter.

In September, there was a small increase in the domestic production of crude oil and natural gas liquids. A 17 thousand barrel a day increase in Louisiana indicated the beginning of recovery following the over 100 thousand barrel a day curtailment of crude production which resulted from hurricane Camille. Alaskan crude output reached a record 219 thousand barrels a day – 21 percent above the year earlier level and 11 percent above the prior month's production.

INVENTORIES

Stocks of all oils at the end of September amounted to 1,034 million barrels, only a million barrels higher than a year ago. Individual product inventories appear to be in good shape. Distillate fuel oil stocks are somewhat below the record high level which was reached in September last year, but they are more than 10 million barrels higher than in any previous year. Residual fuel oil stocks, too, have dropped back from last year's record level.

The inventory build-up in September was on the heavy side – 28 million barrels were added to refined product storage. Crude oil stocks, on the other hand, were drawn down by 5 million barrels, resulting in an over-all inventory accumulation of 23 million barrels for the month.

PRICE

On the West Coast, wholesale prices of both premium and regular grade gasoline dropped a half cent a gallon in September. They are now at their lowest level for this month in the past two years. Mid-Continent premium and regular grade gasoline closed September with ½ cent recovery, after having suffered a full cent decline in August. Compared with a year ago, however, gasoline was still down ½ cent a gallon, and was as much as ¾ cent a gallon below the level of two years ago.

Distillate wholesale prices increased ½ cent in the Mid-Continent area to 9.5 cents per gallon – ½ cent above the year earlier level. Chicago wholesale prices for heating oils moved .15 cents a gallon higher during the month. This restored prices to the same level as prevailed prior to the .15 cent drop of July 1.

There was substantial improvement in propane prices during September. The increases amounted to three-quarters of a cent a gallon in New York harbor and a full cent a gallon in the Mid-Continent. Propane prices in both these markets are now above year earlier levels but they still have a long way to go before they can be considered normal.

THE STORY OF COAL – PART I

Since the United States came into being, nearly two hundred years ago, 40 billion tons of coal have been mined. Coal fueled our transition from an agricultural nation to the greatest industrial power in the world. As other sources of energy were developed, coal was obliged to surrender a part of the energy market, but it was not until 1950 that it was dislodged from its long held first place. During the nineteen fifties, the use of coal declined. But by 1960 the decline was arrested, and since that year coal consumption has grown steadily.

More than 500 million tons of anthracite, bituminous and lignite coals were consumed in the United States last year. Coal mines provided the energy equivalent of 6½ million barrels of oil per day, or fully one-fifth of all the primary energy used. In addition, another fifty million tons were produced for export markets. These tonnages are huge indeed but they are insignificant compared to the available reserves of domestic coal.

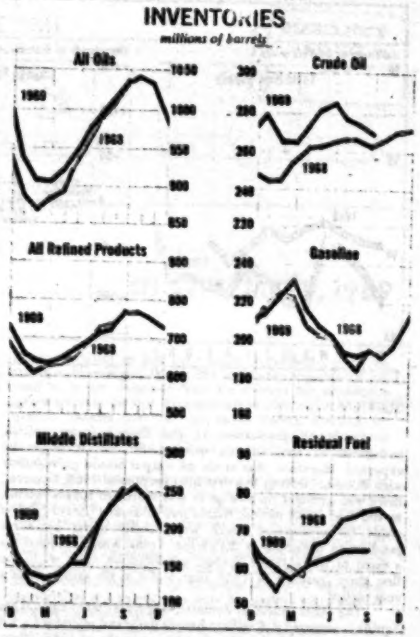
Coal deposits are found in 34 of the 50 states, and economically recoverable reserves of all types are estimated at nearly 800 billion tons. Last year's production rate, therefore, could be maintained for nearly fifteen centuries before existing domestic resources were exhausted. These raw figures, however, tell only part of the story. Bituminous coal reserves will not satisfy needs for anthracite coal, nor is it feasible to fuel utility boilers on the East Coast from coal fields in Colorado. Quality and other economic considerations also trim the real marketability of some deposits, but even so there is positively no question about the adequacy of our national coal supply.

Although reserves are found in many parts of the United States, more than 90 percent of domestic consumption occurs in the North Central and East Coast regions of the country. These areas include the principal coal producing states – Pennsylvania, West Virginia and Virginia in the east, and Kentucky, Illinois, Ohio and Indiana in the central region. The freight element represents such a large proportion of the delivered cost of coal – as much as 40 percent in many cases – that major markets have developed only within a limited distance from production centers. Currently, large new mines are being opened in some of our western states to fuel electric power stations. But, basically, the future for coal continues to lie east of the Mississippi.

There are hundreds of varied uses for coal, oil, natural gas and other fuels. For convenience, they can be grouped into four major markets for primary energy: Industrial-Commercial, Transportation, Electric Utilities, and Residential. The Industrial-Commercial market is by far the largest and accounts for 38 percent of over-all primary energy consumption. It comprises the needs of many diverse forms of economic activity. Among them are heat for large buildings, fuel for industrial processing and such non-energy uses as paving materials and chemical feedstocks.

Second in size are the energy requirements of all forms of land, air and water transportation. They currently represent a quarter of the total. In third place with 22 percent of the market, and growing fastest, are the needs of Electric Utilities for generation purposes. Accounting for 15 percent, the Residential market is the smallest of the four categories. This market includes various uses for energy, but home heating is the primary one.

Coal is consumed in all four energy markets but its volume varies both by market and by region. In the transportation category, for example, coal has been practically eliminated due to changing technology. The railroads began to convert from coal to more efficient oil-burning locomotives in the late thirties. This change was delayed because of other defense requirements during World War II, but the conversion program was resumed in the post-war period. In 1950, nevertheless, almost three-quarters of all locomotives in the country still burned coal and sixty million tons a year were mined for this purpose. As more and more diesel locomotives were brought



into service, this substantial outlet for coal disappeared in a few short years. The coal used for railroad fuel today is burned primarily in the mining regions, and the volume is so small that it is no longer significant. The other transportation usage for coal – fuel for ships – has also been eroded by technological advances. Older vessels, primarily those active in the Great Lakes trade, still consume almost half a million tons of coal annually. But all new ships are powered by diesel or residual fuel oil. As the older coal-burning vessels are gradually retired, therefore, this market will dwindle away, too.

The coal industry has had a similar painful experience in the Residential energy market over the past twenty years. Consumption trends have tended to follow those in the Transportation sector, although the slide has been less pronounced. After World War II, homeowners were attracted toward oil and natural gas for heating purposes. These fuels were slightly more costly but offered excellent burning characteristics and, more importantly, eliminated the unpleasant dust, storage and ash handling problems associated with coal furnaces. This convenience factor coupled with effective marketing techniques by the petroleum industry led to coal's decline.

As recently as 1950, coal was still the dominant fuel for home heating. It served the needs of nearly half the market. But in subsequent years, coal lost this position and currently it provides less than 6 percent of the primary energy used in the Residential market. Natural gas, with a 52 percent share, is the market leader now. Most of the remaining homes heated by coal are located close to the Appalachian and Mid-Western mining regions, and they burn less than twenty million tons per year, or 4 percent of total coal consumption. Many of these homes may be converted to other fuels during the seventies. By 1980, therefore, residential coal consumption is

expected to drop to about half the current level and represent only a very minor share of the over-all market.

The Electric Utility market is by far the most important outlet for coal among the major categories. It accounts for 60 percent of total domestic sales at present and will become proportionally even more important in the future. Last year more than half the electrical power used in the United States was produced in coal-fired generating stations. In certain geographic areas the proportion was even higher. The North Central region, for example, used coal to meet four-fifths of the electric utilities needs. Another important market is the East Coast area where coal accounts for nearly two-thirds of the generation of electricity. Energy consumption by utilities constitutes a very large market, so enormous volumes of coal are involved. In 1968, almost 300 million tons were burned under utility boilers throughout the nation.

The outlook for increased coal consumption by electric utilities is bright. But inter-fuel competition is intense and air pollution restrictions against sulphur or other emissions pose substantial problems for the coal industry in many areas. In the burning process all fuels – coal, oil and gas – release sulphur and other pollutants in varying degrees. Coal, however, has the greatest difficulties in this respect. The industry must hold down the delivered cost of coal and at the same time devise methods to meet more stringent and widespread air pollution regulations if it is to realize in full the opportunities for increased sales to utilities.

Although the Industrial-Commercial market for primary energy is the largest of the four major categories, it ranks only second in importance for coal. Until 1955, coal reigned as the dominant energy source in this market. But in the following years, it was displaced by natural gas, which had become available in substantial quantities and at very low prices. Oil also offered vigorous competition in the Industrial-Commercial market. To an extent, it too was partly responsible for the decline in coal demand.

The Industrial-Commercial market, however, remains an important outlet for coal even though its market share is falling. In 1968, more than 190 million tons, or two-fifths of total coal sales, were made to these customers. Roughly half of this volume was used by the steel industry to produce the coke needed in the steel making process. Growth in the sales of coking coals, however, has tended to be very slow because of progress made by the steel industry in reducing the volume of coke required to produce a ton of steel. Technological improvements have reduced this quantity by fully a third since 1950. During the same period, the use of anthracite and bituminous coal by general industry declined by more than twenty million tons. The drop primarily reflects competition from alternative sources of energy. But it was also the result of mounting public demand for cleaner air. The coal industry has not yet succeeded in developing economically efficient methods to remove air pollutants given off by coal-fired industrial plants. The industry is losing coal customers today and seems likely to lose more in the future unless it can solve this difficult problem.

Coal makes a major contribution to the energy needs of the United States, so it is comforting to view the almost inexhaustible supply of domestic reserves. During the coming decade sales are expected to increase – particularly to electric utilities. In addition, a new future for coal may develop through its conversion to a cleaner, more convenient gaseous or liquid form of energy. Certainly, it will be within our national interest to attempt to utilize our wealth of natural coal resources.

THE PETROLEUM SITUATION

RELEASE: NOVEMBER 28, 1969

IN OCTOBER, 1969

DEMAND

With the peak season for gasoline consumption having passed, attention is now focused on the demand for distillate fuel oils. Distillate registered an increase in October in line with the long-term trend. It is probable that most of this gain was brought about by greater use of highway diesel fuel, with only a minor portion of the increase reflecting higher demand for heating oils, even though temperatures during September and October were colder than last year.

Weakness in gasoline and naphtha jet fuel limited the total demand for petroleum to a 3.7 percent gain during October. Gasoline increased only 2.9 percent following exceptional strength last month. The demand for naphtha jet fuel was 42.6 percent below last year. It was the lowest level of naphtha jet demand since February 1966.

Residual fuel oil registered an impressive gain of 7.5 percent. This increase, however, was largely a recovery from an abnormally low level of demand a year ago.

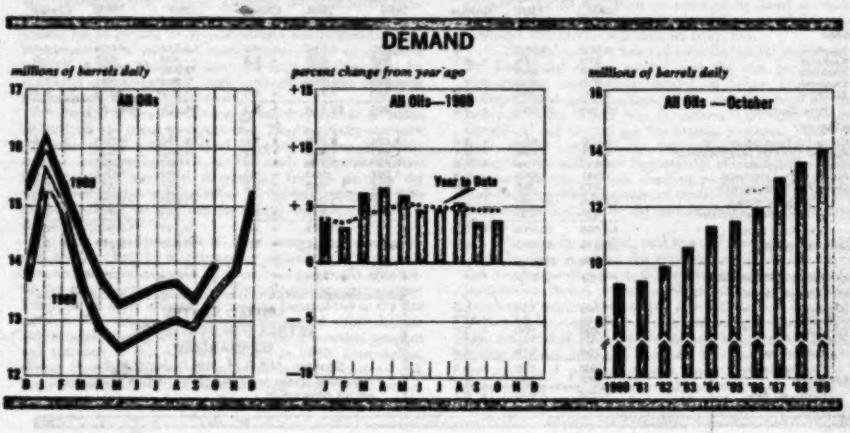
SUPPLY

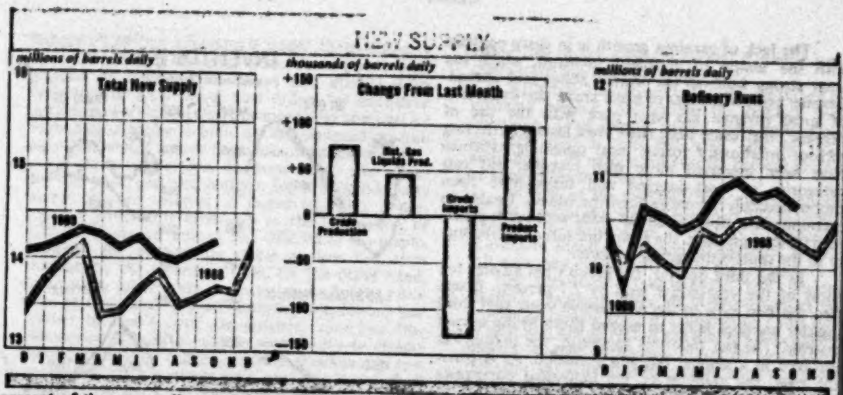
Domestic production of crude oil and natural gas liquids in October averaged 120 thousand barrels a day more than in September. Crude production increased 75 thousand per day primarily because operations in Louisiana returned to normal following the hurricane in August. Despite a higher allowable factor, crude oil output in Texas was virtually unchanged from a month ago. Reflecting seasonal trends, the production of natural gas liquids rose by 45 thousand barrels a day.

Total imports in October were slightly lower than a month ago. Residual imports increased seasonally, offsetting, to a large extent, the decline in crude oil and other refined products. Refinery runs averaged 10.7 million barrels a day during the month—a decline of 158 thousand barrels a day from last month.

INVENTORIES

The amount of crude oil and refined products in primary storage at the end of October was within 1





percent of the year-earlier stock level. At 1.03 billion barrels, the total was 9 million less than a year ago. Gasoline inventories reached 198 million barrels—only 5 million above the year-earlier level. Kerosine stocks, at 50 million barrels, were also 5 million higher than a year ago and are regarded as somewhat excessive. The excess reflects a rate of demand that has fallen below expectations. Distillate inventories, amounting to 207 million barrels, were down from the year-earlier level by 5 million. There was a larger decline for residual fuel of 11 million barrels. At 66 million barrels, however, residual stocks were in a better position relative to requirements.

PRICE

In the highly volatile Mid-Continent gasoline market, prices rose ½ cent a gallon in October. Added to last month's ¼ cent increase, the gains represented a partial recovery from the decline in August, when prices fell a full cent a gallon. Despite the increase in the Mid-Continent, gasoline prices at the end of the month were generally below the levels of recent years. The East Coast was the only major wholesale gasoline market in which posted prices were not under the levels of two years ago. In the Gulf Coast area, wholesale gasoline prices declined ¼ cent a gallon. They are now ¾ cent a gallon below their summer peak.

In contrast to gasoline prices, distillate postings in all major markets at least equalled the levels of one and two years ago. They moved up ¼ cent a gallon in Chicago but down by the same amount in the Mid-Continent. The decrease in the Mid-Continent, despite sharply lower temperatures in many Midwest states, was regarded as recognition of common discounting rather than new price softening. Kerosine prices also compared favorably with the levels of recent years, except at the Gulf Coast. In that market, kerosine was priced a full cent below a year ago. And even kerosine jet fuel was available for less than the price of regular grade kerosine last year. But in the Chicago market, kerosine prices increased ¼ cent a gallon to a level ½ cent above a year ago. The wholesale price of residual fuel advanced 5 cents a barrel on the West Coast.

G.J. Shuttlesworth

INTERNATIONAL OIL

During the first nine months of this year, demand for oil in the Free World averaged about 37 million barrels a day. This was a gain of 8 percent over the same period last year. In the U.S., demand rose by 5 percent, and in the foreign sector, requirements increased 10 percent.

Reflecting the expansion in demand, Free World crude oil production registered a 7.7 percent gain—right in line with the long-term trend. Most of the 2.4 million barrel a day growth was in the Free Foreign areas. In fact, two-thirds of this volumetric increase was concentrated in Libya, Iran, and Nigeria, each country contributing about 500 thousand barrels a day to the total gain. The Nigerian increase, of course, reflects a recovery from the effects of last year's Civil War. But Libya and Iran were the scenes of actual growth. In Libya, an all time high of almost 3.1 million barrels a day was attained during the nine month period.

The growth of oil production in other countries varied widely. Saudi Arabian production dropped slightly in the first half of 1969. But in September, it hit a record 3.2 million barrels a day with the result that output in the third quarter averaged more than 3 percent above the level reached in the same period last year. In Egypt and Indonesia, the January-September period saw very large gains—45 percent and 26 percent, respectively. But in Venezuela, production averaged 1.5 percent below the 1968 level. And in the United States, it registered a mere 0.2 percent rate of growth.

S.I. Semos

EARNINGS

In the first nine months of 1969, the combined net income of the large group of petroleum companies this Bank has under continuous survey fell slightly behind the earnings recorded in the same period last year. It was the only time since 1958 that the group has failed to achieve a growth in earnings. Because 1958 was marked by a rather severe business recession, some petroleum industry sources have been prompted by the earnings performance this year to wonder if the nation might not be experiencing another recession.

The lack of earnings growth is in sharp contrast with the tempo of petroleum demand, which has been strong both in the United States and abroad. Despite price weakness in some areas, the expansion of gross revenue has kept pace with the rise of demand. But costs have risen even faster. Reflecting various inflationary forces, most operating expenses have been increased more than revenue. But two categories of cost—interest and taxes—have risen proportionately far more than the others. Unable to accommodate all its financial needs with funds generated from operations, the group has turned increasingly to the short-term capital markets.

In the third quarter, the group's net income fell short of the year-earlier level by 2.7 percent. It was also the first time in the past twelve years that third quarter earnings failed to exceed those of the second quarter. The last time this happened, the nation was involved in a general business recession. As is often the case, the earnings of the individual companies varied substantially from the average performance of the group as a whole.

Richard C. Sparling

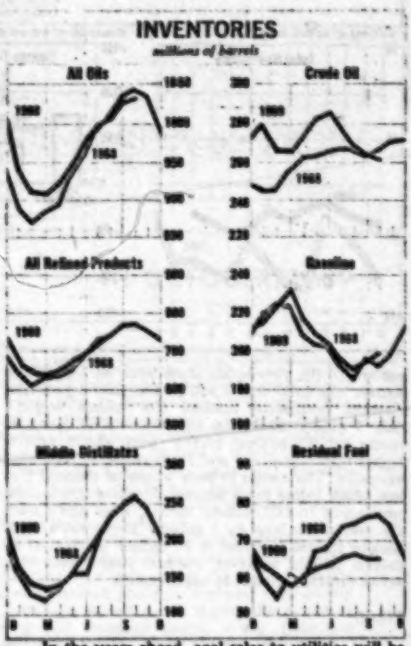
THE STORY OF COAL – PART II

The nation's requirements for primary energy in the next decade will be enormous and domestic reserves of petroleum—both oil and natural gas—are likely to be inadequate to support the potential demand. But, as was pointed out in last month's report, there is no need for concern in regard to coal. The real challenge is to devise economic methods to utilize more fully this nation's abundant coal deposits.

Consumption of solid fuels in the Transportation and Residential Markets has been declining for years and this trend is expected to continue. Although some growth is expected for coal in the Industrial-Commercial Market, gains are likely to be minor. The electric utilities, however, constitute the most important outlet for coal and will continue to do so in the future. The oil equivalent of nearly seven million barrels per day of all types of energy was used to generate electricity last year, and utility requirements will more than double by 1980. Coal is the source of more than half of this energy.

Many generating stations are designed to burn more than one form of fuel—coal, oil or natural gas—and can switch from one to another when economic considerations dictate a change. The coal industry must continue, therefore, to hold down costs and improve technology if it is to retain a competitive position. A new threat to coal's dominance—nuclear energy—will also have a significant impact in the Electric Utility Market in the years ahead.

Each major region of the United States provides a different pattern of utility fuel usage. In the Gulf Coast area, for example, most utilities use low-cost natural gas from nearby fields to generate electricity. On the West Coast, water power from hydro-electric sites provides almost sixty percent of all the energy needed. But on the East Coast, coal is the source of nearly two-thirds of the energy used for generating purposes. And in the largest regional market—the North Central area—coal represents more than three-fourths of the primary energy utilized by utilities.



In the years ahead, coal sales to utilities will be influenced by different factors in each region. On the West Coast, the limited potential for expansion of hydro-electric capacity is a factor favorable to coal. Western utilities are turning to coal deposits in Wyoming, Utah, Arizona and New Mexico to meet part of their expanding requirements. Twelve new coal-fired generating stations with a combined capacity of 4.5 million kilowatts are already under construction in these states, and others are planned. These large coal plants each consume the oil equivalent of 25,000 barrels per day. Power produced in these plants will be transmitted along extra-high voltage transmission lines for hundreds of miles to centers of consumption in the West Coast region. Currently, the coal used to generate electricity for the West Coast amounts to less than ten million tons. But, by 1980, consumption is expected to reach 70 million tons.

Another development of potential benefit to coal in the East Coast and North Central regions is the probability that domestic natural gas will be in short supply within a few years. Because utilities pay less for their energy than do other users, the natural gas that is available is likely to be channeled into more profitable markets. As a result, many electric utilities may be forced to turn, at least in part, to coal to make up the deficit.

There is another side to the coin, however. The rapid introduction of nuclear power in several areas, will restrict the growth of coal markets. Electric utilities at present have only 3 million kilowatts of nuclear generating capacity in operation, but a

further 67 million kilowatts is under construction or on order. During the past year, these plants were plagued by construction delays and sharply rising capital costs. As a result, new orders for additional nuclear power stations have dropped very sharply. An expanding capacity to build nuclear powered generating plants should relieve the bottlenecks, however.

Substantial uranium discoveries have also occurred this year, and the outlook for a fully adequate supply of ore reserves is improved. This factor, together with rising efficiency in the production of kilowatt hours per unit of fuel utilized in the plants, increases the chances for stable nuclear fuel costs throughout the seventies. Coal, on the other hand, faces rising labor costs in many areas. Safety problems at the mines and air pollution regulations add further to coal's cost. On balance, therefore, the economics of nuclear power seem likely to remain favorable in many regions, and the slowdown in new orders for nuclear plants may prove to be of short duration. In the East Coast region, coal faces strong competition from residual fuel oil as well as from nuclear power. And within the past year coal has suffered some reverses. Several East Coast states north of Washington D.C., in an effort to combat air pollution, have imposed severe restrictions on the sulphur content of fuels burned by electric utilities. The petroleum industry has thus far managed to meet the new fuel standards with little change in delivered prices, but the coal industry has been less successful. The result has been a significant switch from coal to oil that has reduced utility coal consumption and, more important, weakened prospects for new coal-burning generating plants in these states. Because it is not yet practical to desulphurize coal, the coal industry must develop other means to reduce sulphur emissions from coal-fired stations—perhaps by the use of devices to remove pollutants from the stack gases. Alternatively, the industry may be able to bring large new deposits of low-sulphur coal into production. In either case, quick action is needed if similar losses in other states are to be avoided.

Although the prospects for coal are mixed in the different regions, nationwide the outlook remains favorable. Total electric utility consumption of coal was 300 million tons last year, and by 1980 an additional 120 million tons—forty percent more—will be needed for this market.

In view of the outlook for domestic supplies of oil and natural gas, serious consideration must also be given to the conversion of coal to a cleaner, more convenient liquid or gaseous energy form. Progress in this area may conceivably allow coal to regain a share of the important Transportation and Residential Markets. Renewed sales to these customers would provide greater utilization of the nation's vast reserves of coal and would reduce the nation's dependence on foreign sources of energy. Research on conversion methods has demonstrated that existing technology is adequate to do the job, but costs must be reduced further if gas or liquids produced from coal are to be competitive with the natural products.

To achieve this aim, the coal industry will have to spend substantial amounts of capital and engage in projects of enormous scale. Large commercial-size plants to produce coal liquids or pipeline quality gas are expected to cost more than $300 million each and require up to twenty million tons of coal per year. The mining part of such a venture alone, will require production two to three times greater than the output of the largest coal mine operating in the United States today.

The outloook for increased sales of coal to existing markets is good during the coming decade, despite mounting competition. And the future is potentially even more promising when the possibilities of converting coal to gas and liquids are considered.

Re: United States v. General Dynamics Corporation, et al., Civil Action No. 67 C 1632 (N.D. Ill.)

Dear Mr. Hedlund:

This letter will confirm the substance of our telephone conversation of many months ago, at which time we discussed my letter dated November 14, 1966 to the Department of Justice in response to their letter concerning the above litigation.

In that letter, you will recall, we cautioned the Department of Justice not to infer from our letter that Electric Energy, Inc. considered the acquisition of the United Electric Coal Companies by General Dynamics Corporation to be in the category of mergers which might lead to a narrowing of the "spot" market for us and tend to increase our fuel costs. When you inquired further in our initial phone conference, I advised you that Electric Energy, Inc. did not think that the United Electric-Freeman merger would have any impact on our "spot" market and did not think that it would in any way adversely affect the competition for our business. As I pointed out to you at that time, the location of Electric Energy, Inc.'s generating station on the Ohio River is such that coal produced in the Belleville freight rate district where United Electric's Fidelity mine is located could not be shipped to us at that time on a competitive basis with coal produced in the Southern Illinois and West Kentucky districts. This was true at that time regardless of whether the coal had been offered on a contract or spot basis. Because of the freight rate disadvantage, Belleville producers are not able to compete at this time for our business unless we were to be given the advantage of a unit train movement rate, not presently existing.

In my letter to the Department of Justice I was attempting to point out to them that Electric Energy, Inc. would be concerned about mergers between producers located in the Southern Illinois and West Kentucky freight rate districts - areas from which we secure our coal.

In view of your indication to me last week that my letter of November 14, 1966 is being introduced into evidence in the law suit, I am happy to write this letter to make our position perfectly clear in this regard.

Yours very truly,

V. H. Clark
Secretary-Treasurer

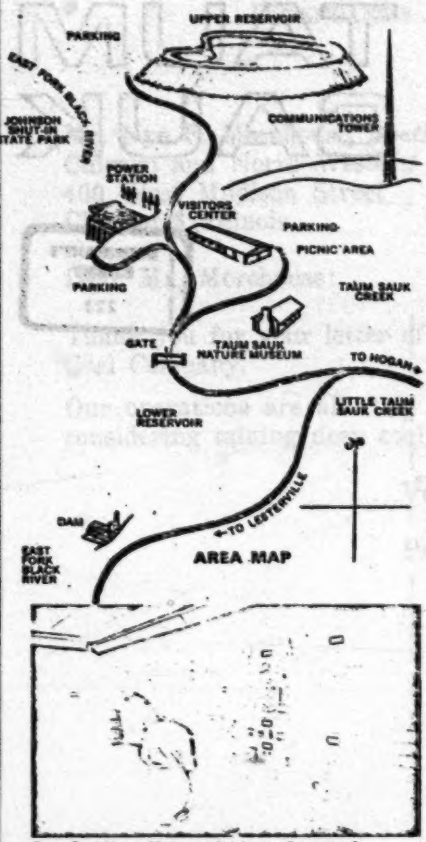
UNION ELECTRIC COMPANY
315 N. Twelfth Blvd., Saint Louis, Mo. 63166



Taum Sauk Nature Museum adjoining the Reception Center exhibits natural resources of the state of Missouri. Displays of geological formations, wood and clay resources and their end products, birds and wild flowers, mammals, etc. are included at the museum.

Union Electric Welcomes You!

A by-product of hydroelectric power stations is the opening up and improvement of certain areas that have recreational potential. It is our policy to make the most of that potential for the benefit of the public. This is in keeping with our responsibility as supplier of an essential public service.

You are welcome to enjoy the facilities we have installed to make your visit more comfortable and to provide access to points of interest. We are doing all we can, within the bounds of safety and economy, to conserve and enhance the forests, waters, fish and wildlife that together make the area appealing to you. We ask that you cooperate.

Taum Sauk is the pumped-storage hydro plant of the Union Electric Company, a business managed, investor owned utility serving over 2,300,000 people in Missouri, Iowa and Illinois.

Taum Sauk is one of the few and one of the largest plants of its kind in the world. The Taum Sauk plant serves a special purpose in the power supply of Union Electric, an electric system on which a variation of only seven degrees of daytime summer temperature can cause a load change of as much as the entire capacity of this plant. Pumped hydro is ideally suited to this type of service. A pumped hydro plant is not dependent upon rainfall, since the water required to operate it as a generating plant is pumped into the high elevation lake by its own hydroelectric equipment. Pumping is performed by the simple reversal of rotation of the generating units. Power for this pumping comes from the excess steam turbine generating capacity available at night and over the week ends when the use of electricity by customers is greatly reduced. For each three cheap night kilowatt hours used for pumping, two daytime KWH are returned when they are much more valuable. In addition, the Taum Sauk plant is an important reserve for emergencies.

The rock walls of the upper pool rise 84 feet above the reservoir floor and are concrete lined. They are topped by a 10-foot high parapet wall to permit additional storage of water. The floor is paved with asphalt and covers 39 acres. This reservoir will hold a billion

and a half gallons of water weighing some five million tons, and is 55 acres in area at the top.

Water flows from this upper reservoir down through a vertical shaft 431 feet deep and then races another 400 feet down hill through a tunnel, 6,600 feet long. The lower 1,800 feet of this tunnel is lined with steel tubing 18½ feet in diameter, which carries the water out of the mountain and down to the turbines. From the turbines it passes on into the lower lake. During pumping, this flow is reversed and the water is restored to the upper lake.

The lower lake spreads over nearly 400 acres, and is formed by a small dam across the East Fork of the Black River, which contributed the water for the initial filling and provides a very small amount of water for evaporation and seepage. During generation, the elevation of this lake rises 15 feet in eight hours, and when pumping it drops by the same amount in twelve hours. Level gauges, and automatic valves in this dam, maintain the total volume of water in the two lakes at an amount equal to that of the lower lake when full. In this manner the natural inflow to the lower lake is at all times automatically passed on down stream, except during high flood when some variations may occur.

The Taum Sauk plant has an output rating of 350,000 Kw. Operation is automatic, remotely controlled from the Osage plant and from the Dispatchers' office in St. Louis. The cost of the plant was approximately $50,000,000 and it went into service in the summer of 1963.

We hope that you enjoy your visit and ask you to help us keep the area unlittered so that those who come after you may enjoy their stay.

LOCATION: In Ozark Highlands near Lesterville, Mo. (Reynolds County), 90 airline miles southwest of St. Louis.

COMPLETION DATE: August, 1963.

COST: $50,000,000 (includes $10 million for transmission lines).

CAPACITY: 350,000 Kilowatts

NIGHT PUMPING CYCLE: About 9½ hours, using power at rates up to 400,000 kilowatts.

DAY GENERATING CYCLE: Capable of producing 2,750,000 kilowatt hours of energy. Normal full use expected to be about 2,200,000 kwh daily, leaving 25 per cent emergency reserve.

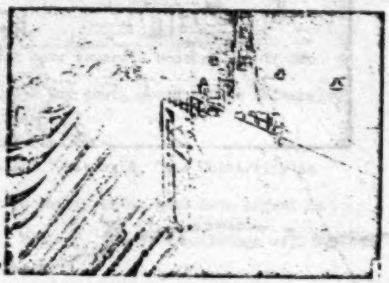
UPPER RESERVOIR: Man-made lake atop a 900-foot mountain, covering an area 55 acres and 92 feet deep, holding 4,350 acre feet of water (8 times the water consumed daily in St. Louis).

LOWER RESERVOIR: A 395-acre pool created by a concrete dam, 60 feet high and 390 feet long, on the East Fork of the Black River, and holding 6,350 acre feet of water. Maximum drawdown during night pumping: 16 feet.

SHAFT AND TUNNEL:
7,003 feet long, 27.2 feet in diameter at shaft, 25.5 feet in diameter at upper reach, 18.5 feet in diameter at lower reach. Difference in elevation between upper and lower reservoirs averages about 800 feet.

WATER FLOW: About 5,000,000 tons of water will be handled in each direction during the cycle of a normal full use day. Water pressure at the power station is about 400 pounds per square inch.

TAILRACE: A 65-foot wide excavation, 1,500 feet long from powerhouse to lower pool.



Dam on East Fork of Black River forms lower reservoir

DEFENDANT'S EXHIBIT 224

FOR RELEASE: P.M. MONDAY, JANUARY 19, 1970

By 1971, no University of Chicago buildings in the Hyde Park-Kenwood area will be heated by burning coal.

This will complete a conversion program begun in the fall of 1967 to help solve the air pollution problem.

The announcement was made today (Monday) by Gilbert L. Lee, Jr., Vice-President for Business and Finance.

According to Lee, the University owns 236 buildings in the area. A total of 118 of these are heated by the University's steam plant at East 61st Street and South Blackstone Avenue. By September, 1970, the steam plant will be using only gas and oil, not coal.

A total of 95 University buildings which have separate heating plants are now heated by gas or oil. Only 22 buildings, 9.7 per cent, owned by the University are still heated by coal.

"In those 22 buildings and the steam plant," Lee said, "the University is well below the minimum requirement for pollution safety which goes into effect in July, 1970. Only low-sulphur coal is burned. However, those 22 buildings will be converted within a year, possibly sooner."

Conversion of the steam plant to gas will cost more than $2,000,000. The annual cost of heating the main quadrangles by gas will be approximately $250,000 above that which it has cost for heating by coal.

"The University's goal is elimination of air pollution," Lee said. "That goal will be achieved."

GENERAL DYNAMICS CORPORATION

DEFENDANT'S EXHIBIT 225

May 25, 1960

Robert A. Bicks, Esq.
Acting Assistant Attorney General
Antitrust Division
Department of Justice
Washington 25, D. C.

Dear Mr. Bicks:

This is a further reply to your letter dated January 29, 1960 to Mr. Earl D. Johnson, President of General Dynamics Corporation, requesting certain information relating to the merger of Material Service Corporation with and into General Dynamics.

We have previously submitted material in connection with Item Nos. 1, 5, 7, 8, and 9 of your letter. I am enclosing herewith the following:

Exhibit A - A summary of the minutes of each meeting of the Board of Directors of General Dynamics Corporation at which the Material Service merger was discussed. (Item No. 2 of your letter.)

Exhibit B - A list setting forth each merger and acquisition by General Dynamics and by companies it has acquired during the period from January 1, 1953 to date. (Item No. 3)

Exhibit C - Copies of statements submitted to stockholders and filed with certain government agencies in connection with such mergers and acquisitions. (Item No. 4)

Schedule II - A schedule setting forth the total value of sales by General Dynamics of its principal products for each year since 1955. (Item No. 6)

COPY

In answer to Item Nos. 10 and 11 of your letter, General Dynamics Corporation had no plans at the time of themerger to use the products and facilities of the Material Service Corporation in its business as it then existed, and at such time there were no plans to use the products and facilities of General Dynamics Corporation in the business of the Material Service Corporation. Since that time the Liquid Carbonic Division of General Dynamics Corporation has supplied Material Service with a portion of its oxygen and acetylene requirements, which are a very minor part of the principal business of the Material Service Division.

In response to Item No. 12, prior to the merger there had been no business transactions between General Dynamics Corporation and Material Service Corporation.

In response to Item No. 13 of your letter, we are submitting a copy of a letter dated November 24, 1959, from Mr. Frank Pace, Jr., Chairman of the Board of General Dynamics Corporation, to the share owners of the Corporation outlining the factors which entered into the decision to merge with Material Service Corporation.

This completes the material submitted in response to your letter. If you have further questions in this connection, please direct them to Mr. Roger I. Harris, Vice President and Chief Counsel of the Corporation, in whose absence I am signing this letter.

Very truly yours,

Ward B. Chamberlin, Jr.
Office of Chief Counsel

Mr. R. J. Hepburn:

Re: Kerr Coal Company

In the afternoon of October 29, Mr. Jerry Swanson of the Freeman Coal Company and I visited the Kerr mine. We both went down into the mine and remained there approximately two hours. Mr. Swanson took measurements and checked the roof bolting and the bony sections of the coal, and he possibly will give a more complete report in the very near future.

We obtained a mine map and pinpointed their present workings. However, my impression—although I am not experienced in this type of mining—is that the problems are not insurmountable.

As pointed out in the Joy report, this is a very hard sandstone. There is no definite way of plotting their patterns. However, economical mining could be done. I feel that possibly one of the reasons for the poor report from Joy is that their type of machines are not readily adaptable to these conditions. If a forecast of the location of these sandstone formations could be made, planning could forecast them and a more productive mining situation could be had.

I got the impression in the mine that the men were somewhat lackadaisical, and poor management is one of the main problems. I can see no reason why this could not be a better-cost, more-profit mine than it is at present.

I understand at this time that the Kerr Coal Company is taking penalties because of their B.T.U. requirements. This quite possibly could be due to the fact that the coal loaders in the deep mine do not spearate the rock efficiently. A jig could be set up to do this. The present equipment would probably have to be abandoned and new equipment required: trackage, etc.

I talked to Mr. Kerr relative to the sampling that they do to check the quality of their coal. They have a belt sampler. However, analyses are taken only once a

week, and they have the same problem we have here—comparative analysis between the power company and the coal company.

I would like to add that I feel that Mr. Swanson of Freeman is going to give a much more favorable report than that handed to us by Joy. I let him read the Joy report. He readily agreed with me that this was not a very true picture. I pointedly asked him if he had this mine, could he profitably run it. He said he would jump with joy at the opportunity.

DEFENDANT'S EXHIBIT 228

Mr. Morris outlined the need for additional stripping equipment at the Fidelity Mine. Present equipment will maintain current production rate in the present pit for approximately eighteen months, at which time, with deeper overburden, the 1650-B would need help to maintain production of approximately 180,000 tons per month.

After mining all of the coal in the present location (Green Pit), the estimated reserves at Fidelity that can be stripped is 23,000,000 tons. This is located in three different areas and shows overburden depths, rock and surface material that would require a machine to help the 1650-B to mine it all out economically. Without a helper, monthly production would be reduced from its current rate of 180,000 tons to approximately 125,000 tons, with resultant cost increase. Also, of this 23,000,000 tons, approximately 10,000,000 could not be mined at all with the one machine (1650-B). The need for additional help is thus established as necessary.

Mr. Morris stated that after thorough investigation, a wheel, properly designed for the particular areas involved, seemed to be the best solution.

The following information and estimates have been developed.

1. Bucyrus-Erie has a standard design and has built a wheel for Peabody and one for Truax. It is high enough for us, but for our purpose certain modifications of design seem necessary. They put a price on their standard design of $2,500,000, and an estimate on transportation and erection of $[illegible]00,000.

While we don't know exactly what the change in design we would need would cost, they have indicated that the engineering and other factors involved would cost somewhere in the neighborhood of another $1,000,000. So it appears we are thinking about something over $3,000,000 for a Bucyrus machine properly designed and in place, ready to operate.

2. We have built four wheels, three of which are now in operation. The W-2 is at Buckheart, the W-3 at Banner, and the W-4 at Cuba. The W-3 was originally at Fidelity Mine but the design of this particular machine did not properly serve the need at that mine and it was not successful there. It was redesigned and moved to Banner and our cost and profit record there will indicate its satisfactory performance.

   The wheels at both Buckheart and Cuba are doing a satisfactory job.

3. We have all of the engineering information and blue prints necessary to build the type of wheel we need at Fidelity. This is quite a cost saving.

   The machine would be built higher, the digging end longer, and the stacker end some longer and higher to place the dirt back far enough in deep overburden to avoid slides. We would use the base, motors and quite a lot of other material from the 5561 Marion shovel which is now a stand-by at Fidelity.

4. Utilizing our engineering knowledge, blue prints, and experience, and building the machine on the site, would effect considerable savings. The repair parts in inventory for the 5561 and also repair parts in inventory for Wheels 2, 3 and 4 would be available for the W-5 machine.

5. Our estimate of the total cost, using our own people for the engineering and supervision, and contracting for the welding, erection and so forth, is $1,800,000. We feel our estimates are within reason and have included in the above figure $200,000 for contingencies and unexpected difficulties.

In our five-year budget for capital expenditures, we included $250,000 in 1966 and $1,750,000 in 1967.

We can build this machine and have it in operation within fourteen months. The best estimate from Bucyrus is eighteen months and probably longer.

After discussion, upon motion duly made by Mr. Nugent, and duly seconded by Mr. Thorson, the following resolution was unanimously adopted:

> RESOLVED, that management be authorized to proceed with the necessary purchasing and contractual arrangements to build Wheel No. 5 for use at the Fidelity Mine at a cost of not to exceed $1,800,000.

The Chairman then stated that the next order of business was consideration of the payment of a dividend. He presented a certificate by Mr. John T. Murray, Treasurer of the Company, in respect of the Company's current financial condition and related matters, and stated that such certificate would be made a part of these minutes.

After discussion, upon motion duly made by Mr. Thorson, and duly seconded by Mr. Ames, it was unanimously

> RESOLVED, that a regular dividend of forty-five cents (45¢) per share on the common stock of this Company be and the same hereby is declared, payable on the 9th day of September, 1966, to stockholders of record at the close of business on August 24, 1966.

There being no further business, on motion duly made by Mr. Thorson, and duly seconded by Mr. Gebhart, the meeting was adjourned.

J. T. Murray

April 13, 1970

Mr. Donald G. Kempf, Jr.
Kirkland, Ellis, Hodson,
Chaffetz & Masters
130 East Randolph
Chicago, Illinois 60601

Dear Mr. Kempf:

This letter will confirm our phone conversation of April 11. As I advised you then:

1. Illinois Power Company has given consideration to nuclear energy as an alternative to coal in the past and will certainly compare the overall costs of fossil and nuclear in planning future generation;

2. Illinois Power Company had been aware of the United Electric-Freeman affiliation since around 1960 when Frank Nugent and the other representatives of the Crown interests went on United's Board and Johnny Morris replaced Frank Kolbe as President; and

3. Because of the location of the United Electric and Freeman mines as related to the generating stations of Illinois Power Company we had not regarded the two companies as competitors with respect to service to any particular station. Freight costs prevented such competition. After the combination of the two companies this same situation continued so long as I was President of the Company.

Very truly yours,

Allen Van Wyck
Chairman of the Board

CENTRAL ILLINOIS PUBLIC SERVICE COMPANY

GENERAL OFFICES / 607 EAST ADAMS / SPRINGFIELD, ILLINOIS 62701

April 14, 1970

Mr. Donald G. Kempf, Jr.
Kirkland, Ellis, Hodson, Chaffetz & Masters
Room 2900 Prudential Plaza
Chicago, Illinois 60601

Dear Mr. Kempf:

In re United States v. General Dynamics Corporation, et al., Civil No. 67 C 1632 (N.D. Illinois)

This letter will confirm your discussion of the above lawsuit with representatives of our company a few weeks ago. We reviewed with you then the competitive situation concerning the coal supply at our four stations.

1. Our Meredosia generating station is on the Illinois River, in the area generally served by mines in the Fulton-Peoria freight district. We have purchased some dust from Freeman's Crown Mine in the Springfield freight district for this station in the past, but that is no longer available. Because of the transportation charges, screenings from the Springfield freight district would not be competitive with river coal at Meredosia.

2. Coffeen is a mine-mouth generating station, and it would not be possible for mines other than that at the station to compete for its coal business.

3. The only United Electric coal we consume at our Grand Tower generating station is a small amount of carbon.

4. The Hutsonville generating station is in the far eastern portion of Illinois, near the Indiana border, and could not be reached on a competitive freight rate by either United Electric or Freeman.

You have indicated that there might be some confusion concerning the meaning of paragraph 4 of our letter to Mr. Turner, of the Department of Justice, dated October 28, 1966. In the past and

CENTRAL ILLINOIS PUBLIC SERVICE COMPANY

currently, we have found that the prices of each of the two companies for coal offered to the Central Illinois Public Service Company have always been competitive with other available suppliers. We have no idea what effect, if any, the Freeman-United Electric combination will have upon our coal prices in the future.

You have advised us that the Department of Justice has designated our letter of October 28, 1966 as an exhibit in the above lawsuit. In view of this we are pleased to supply you with the information set forth above.

Yours very truly,

K. E. Bowen
President

KEB/bp

MAPP goals and accomplishments parallel the power development patterns of utility integration and savings for consumers proposed in the Federal Power Commission's National Power Survey Report issued late in 1964.

MAPP membership of midwestern power suppliers has more than doubled in less than three years.

MAPP is investigating the feasibility, timing and routing of transmission lines required to integrate the huge hydro-electric potential in Canada with power developments in the United States.

MAPP individual utilities originally planned to install about 70 generating units between 1967-80. Through regional planning the member systems now plan to install only about 35 units but the average size of each will be approximately doubled. This and other generation economies will result in savings of $268 million during this period.

MAPP will operate a Coordination Center which will ultimately employ a high speed central computer to coordinate regional power operations.

These accomplishments coupled with high voltage line construction have demonstrated that locally controlled power suppliers of all types of ownership working voluntarily together will provide the most dependable service at the lowest possible cost.

Low Cost Electric Power And Dependability

DEFENDANT'S EXHIBIT 232

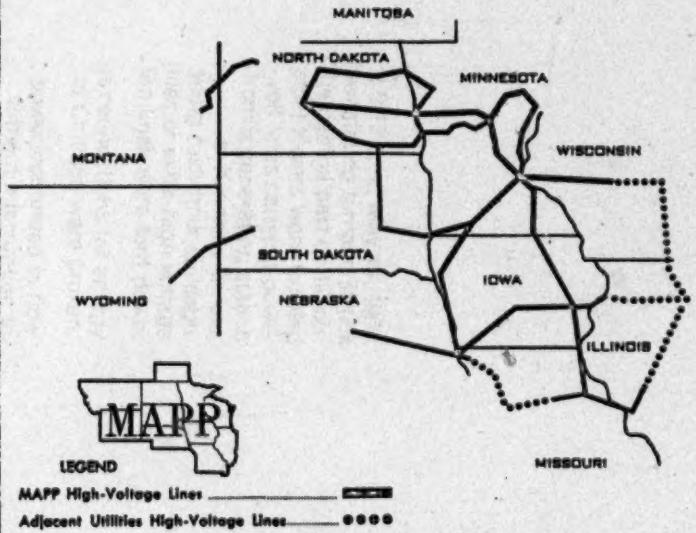
...Through

. . . dependable electric service at the lowest possible cost through coordinated planning and construction of electric transmission and generation facilities in ten states and the province of Manitoba.

MAPP, the nation's first regional power planning organization, is composed of investor-owned utilities, cooperatives, municipalities, public power districts and a Canadian utility.

Planning together MAPP members and several adjacent power suppliers will construct a 5,400 mile network of high-voltage transmission lines by 1980 connecting major power use centers and generating plants. Cost of the lines and associated substations will total more than $230 million. Without MAPP planning this great expansion program would cost many millions of dollars more.

MAPP HIGH-VOLTAGE NETWORK



4,500 Miles of High-Voltage Lines Already in Progress!

Since its organization in early 1963 Mid-Continent Power Planners (MAPP) has made significant progress. Transmission lines and associated electric equipment will be built and owned by the utilities they connect and through whose territory they pass. MAPP will help determine where these lines should be built and when they will be needed.

Mid-America Interpool Network

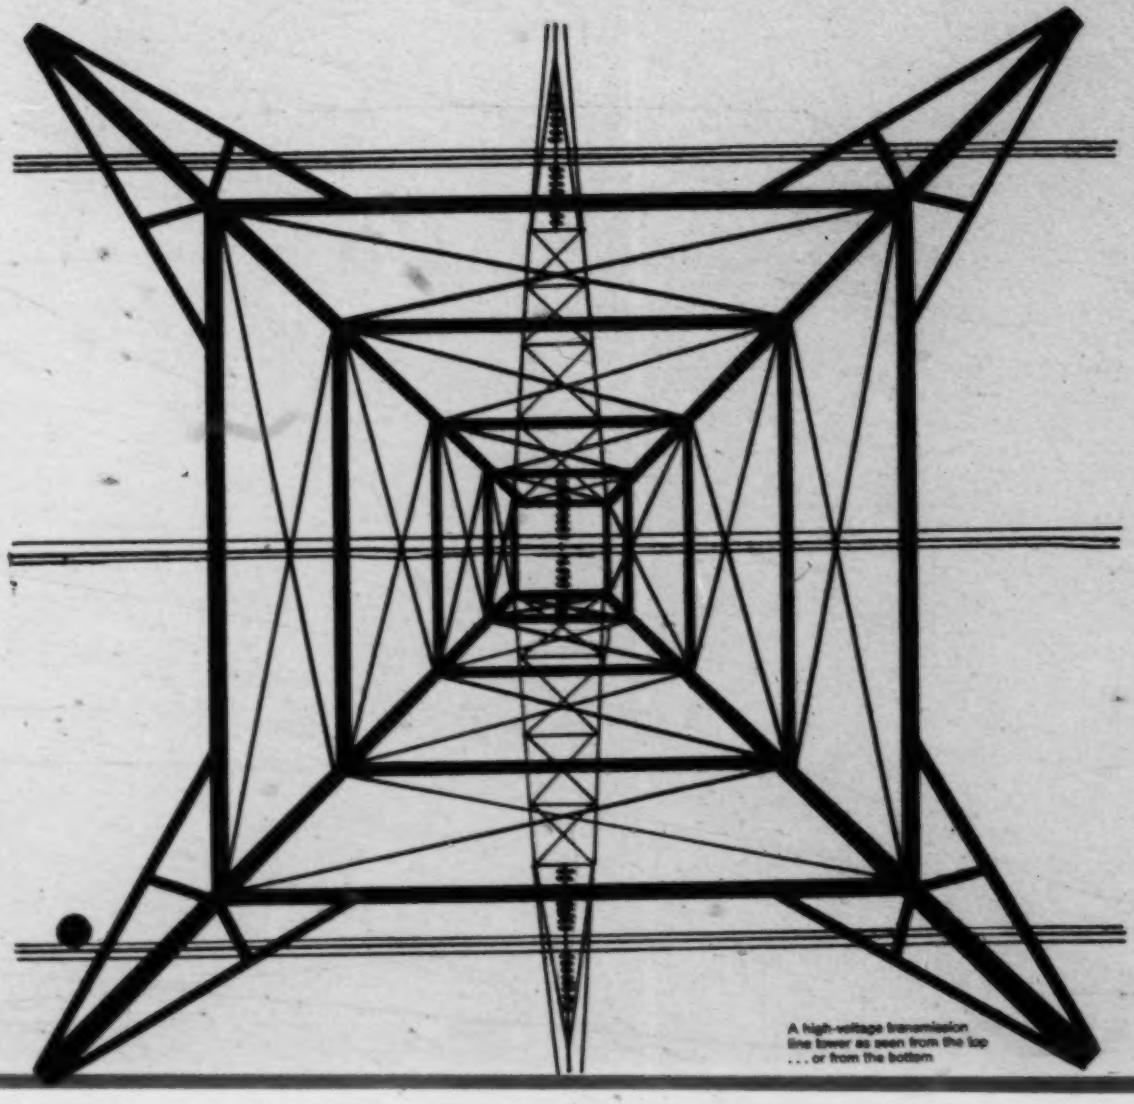
DEFENDANT'S EXHIBIT 233



A high-voltage transmission line tower as seen from the top . . . or from the bottom

At 5:12 p.m., May 15, 1968,
a devastating tornado struck
the central part of Illinois.
Eighty-six steel towers were toppled
with two 345,000-volt lines carrying power
200 miles from a generating station
at Kincaid, Illinois,
to a bustling rush-hour Chicago.
Twenty miles of extra-high voltage
transmission lines were torn down.

Both direct connections for energy
from Kincaid to Chicago were broken.

Yet, in Chicago, power continued to flow
without interruption to
Commonwealth Edison Company customers.
Elevators ran in high-rise buildings.
Rapid transit electric trains moved
downtown throngs home.
Throughout the metropolitan area,
housewives prepared evening meals.
Children's TV was not disturbed.

Kincaid maintained its production
as transmission lines of MAIN
partners—Illinois Power Company,
Central Illinois Public Service Company,
and others—relayed the energy
to other lines serving Chicago.

Years of planning paid off
in an emergency, automatically.

This was **main** at work.

main

The Mid-America Interpool Network is an organization of power systems serving major load centers in the Middle West. There are 19 regular members consisting of 18 investor-owned power companies and one rural electric association. In addition, there are four liaison members from an adjacent coordinating group. Also, associate memberships are available to municipal and other small electric systems.

MAIN's prime purpose is to assure the reliability of electric power production and transmission throughout the region it serves. How does it work? MAIN members coordinate such functions as planning, construction and utilization of generating and transmission facilities on a basis that takes into account the needs of the entire region. This enables all MAIN affiliates to engineer, build, maintain and operate their respective power supply systems in a manner consistent with the utmost dependability and efficiency.

the goal of reliability

Somewhere in Wisconsin, or Illinois, or Missouri, or in any other Mid-America state, a child's hand touches a switch and the darkness of a room turns to light. Hundreds of miles away giant machines automatically make a hairline adjustment. Another hundred watts is on the line—*instantly*.

This natural action—turning on the light is so simple, and its results so certain, it has long ceased to be a wonder in a modern world, even for children. Still, this miracle is the subject of constant and sophisticated development and research, of improvement on a day-to-day basis and of a continuing drive toward the goals of highest quality and reliability of service.

Coordinated planning to increase reliability is an established way of life in the electric power industry. Begun many years ago, the voluntary cooperation among separately managed power companies has now evolved into 12 major networks of power systems serving the entire United States. The ready availability and dependability of electric energy for productivity, comfort, convenience and safety in industry, commerce, farms and homes is to a great extent the result of the coordinated activities carried on by these regional power pooling organizations.

This is the story of one of these voluntary associations

main

the Mid-America Interpool Network.

organization

Historically, MAIN is an outgrowth of a trend that developed in the early 1930's when Midwest power companies began to connect their transmission lines to each other to fortify their reliability and gain the advantages of diversity and economy. After World War II, these interconnections were expanded and the philosophy and techniques of network activity developed rapidly.

During the last decade, increases in generating unit size and improvements in the technology of extra-high voltage transmission have lent themselves naturally to a dual objec. :
(1) Increased reliability and protection from large-scale outages by planned utilization of available power from neighboring utilities, and
(2) Economies resulting from coordinated scheduling of new production and transmission facilities and the maintenance of such equipment.
The coordinated management of interconnected generating units and transmission lines has also enabled MAIN companies to utilize to the best advantage any surplus power that becomes available on a day-to-day basis from larger, more economical units.

More or less informal, yet binding, agreements gradually drew MAIN members closer and closer together in mutual planning and led to the formal organization of the Mid-America Interpool Network in November 1964.

MAIN and the forerunning associations of its members have compiled a long history of working for reliability of service through coordinated planning and operation of interconnected power systems. Members of MAIN aided in the preparation of the Federal Power Commission National Power Su. -y

and some of the policies and patterns established by MAIN are considered models of inter-company system cooperation.

The accompanying map exhibits the geographic expanse of MAIN and its overlapping relationships with other regional power groups. It should be noted that American Electric Power system and three Indiana utilities as liaison members of MAIN provide coordinated relationships with power systems to the east. To the west, Union Electric Company in St. Louis maintains liaison with the Missouri-Kansas Pool for additional avenues of cooperation. Toward the northwest, some of the MAIN area overlaps the area of the Mid-Continent Area Power Planners (MAPP). To the south, Associated Electric Cooperative, Inc. provides access to relationships with the Southwest Power Pool. And the Illinois-Missouri companies and AEP are in coordinated contact with the Tennessee Valley Authority to the southeast.

As a result, MAIN is the Midwest hub of a power pooling effort that directly affects and improves the reliability of electric service to 23,100,000 people in nine states. And through its coordinated relationships with other pools and systems, it vitally aids the cause of reliability through a much wider region of 15 states.

how main operates

The work of MAIN is performed by an Executive Committee consisting of representatives from each of the participating major groups, and by Engineering and Operating Committees. Their function is to do the detailed work of system coordination . . . to improve the already high reliability of the power supply in the Midwest.

MAIN's Engineering Committee regularly tests the soundness of individual company and pool plans by reviewing their effect on the region. To accomplish this, the Committee studies such matters as regional transmis. power flows for normal and emergency system conditions, system stability, and the ability of the interconnected systems in the region to cope with possible major catastrophes.

By using high-speed computers to perform the needed complex studies, the committee examines specific conditions expected during peak load periods and other critical times. These studies provide information to system operators to help them anticipate and solve problems that may be encountered.

An important function of the Engineering Committee is long-range planning. The committee analyzes the future development of extra-high voltage EHV transmission systems and interconnections among the systems to assure reliable performance.

The MAIN Operating Committee's activities include the establishment of adequate communication channels between companies, coordination of generating unit maintenance, formulation of procedures for system protection and investigation of disturbances of major consequence.

The MAIN Coordination Center has been operating in the Commonwealth Edison Building in Chicago since April 1, 1967. This Center maintains hour-by-hour communications with the major members of the MAIN group and with similar centers in other regions. Its staff collects, analyzes and disseminates information on all operating conditions in the region which might affect interconnected operations. Here, maintenance down time or planned outages of major generating and transmission facilities are closely coordinated to avoid combinations of outages which might threaten system reliability. By such activities, the Center provides an operating overview of the entire region—for the entire region.

reliability and the future

Reliability is not a stand-still thing. Projection of electric load growth shows that the nation will need twice as much power producing capability in 1980 as required in 1970.
In building for this future growth, the coordinated planning and performance of MAIN companies will produce their greatest benefit.

In 1968 alone, MAIN members strengthened their interconnected power supply systems with the addition of 4.5 million kilowatts of generating capacity, a 12.3 percent increase.
In the same year, 600 miles of new 345,000-volt transmission lines were added, a 16 percent increase.

During the five years, 1969 through 1973, MAIN companies plan to install 28 million kilowatts of generating capacity, a growth of 55 percent.
In that period too, the transmission system will be strengthened by the construction of over 3700 miles of 345,000-volt lines, an increase of 85 percent.
Also, a network of 765,000-volt lines will be placed in service to provide a new and stronger backbone for the interconnections that tie MAIN companies together.
Each 765,000-volt line will have the capacity to move 4,000,000 kilowatts from one location to another.

The extra-high voltage transmission system in Mid-America will continue to expand and possibly reach the stage shown in the 1980 map.

This growth, with reliability and strength as its core, calls for maximum planning and effort.

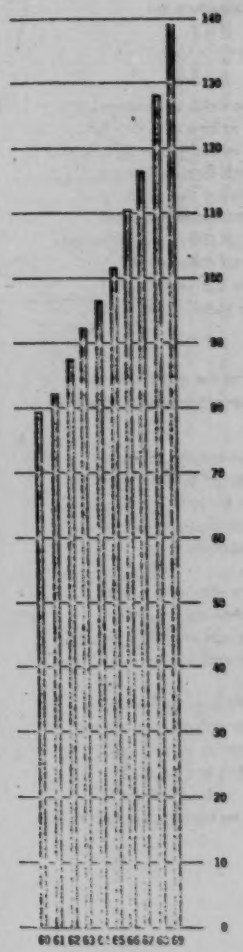
Illinois Power Company - Annual Report 1969

* * *

ELECTRIC REVENUES
Millions of Dollars



Progress in '69

EARNINGS

Earnings per share of common stock in 1969 were $2.67. The increase of 24 cents per share, or 9.9 per cent, over 1968 was achieved even though there were 500,000 more shares outstanding than at the end of 1968.

Net income, which is before provision for preferred stock dividends, was $37,668,000, compared with $33,337,000, an increase of 13 per cent.

Total earnings for the common stock were $35,557,000 as compared with $31,226,000 in 1968, an increase of 13.9 per cent.

DIVIDEND

At its September meeting, the Board of Directors declared a quarterly dividend on the common stock of 50¢ a share, payable November 1, 1969. This is an increase of 5 cents over the previous quarterly dividend.

REVENUES

Revenues from sales of electricity were $138,909,000, an increase of 8.5 per cent over 1968. Gas revenues were $73,825,000, up 11.3 per cent.

ELECTRIC

Electric sales of 7,972,000,000 kilowatt-hours were 9.5 per cent higher than in 1968. Sales to industrial customers, which accounted for 53.6 per cent of all kilowatt-hour sales, were up 10.4 per cent, slightly higher than the increase in commercial and residential sales.

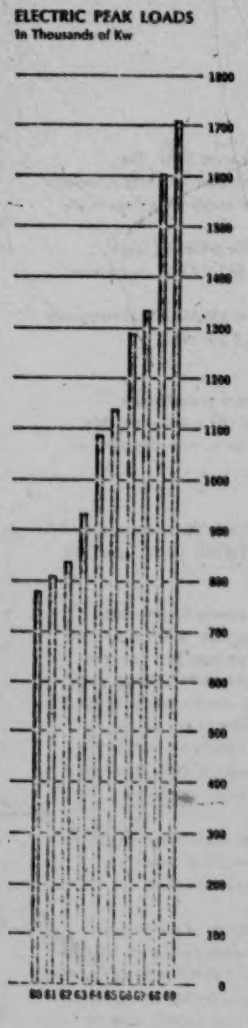
To help meet the increasing demand for electric power in our growing territory, the first 600,000 kilowatt unit of our electric generating station near Baldwin in Southern Illinois is scheduled to go into operation in time for the summer peaks of 1970. Work on a second unit of the same size, scheduled to begin operations in 1973, has begun.

Two 345,000-volt transmission lines from Baldwin station to areas of heavy industry on the Illinois side of the St. Louis metropolitan area are scheduled to be completed before the first unit goes into service.

As a further step to strengthen our capability of meeting peak demands in 1970 and in the future, the Company purchased 170,000 kilowatts of gas turbine generators. Of this, 100,000 is being installed near Granite City and will be ready for service by late spring. The other 70,000 kilowatts being installed near La Salle may be delayed because of a strike against the supplier.

Scheduled construction of electric facilities over the next five years is expected to total $523 million, about $292 million for

* * *



TAXES

In line with national trends, property and other general taxes have continued to increase. In addition, on August 1, 1969, the State of Illinois imposed a 4 per cent income tax on corporations. However, amendment of federal tax laws to reduce the surcharge from 10 per cent to 5 per cent, effective January 1, 1970, and to eliminate this tax on July 1, 1970, will tend to reduce the impact of these increased taxes.

FINANCING

The Company sold 500,000 shares of common stock in January, 1969, at a net price of $18,825,000. The sale of $35 million of 8.35% First Mortgage Bonds in October, 1969, provided an additional $34,694,000. The sale of these securities, together with short-term bank loans, provided the new cash required by the Company during the year.

In January, 1970, the Company sold 500,000 additional shares of its common stock. This sale provided $15,738,000 of the estimated $70 million of new cash which will be required during 1970. The balance of such funds will be provided by the issuance of additional securities, through short-term bank loans, or both.

ENVIRONMENT

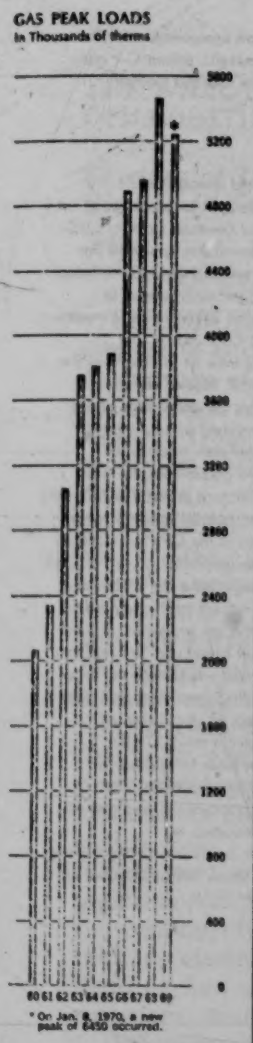
Environmental pollution has emerged as one of the nation's most difficult and urgent problems. For our Company, the main problem is air pollution.

Equipment is available for removing particulate matter from stack emissions and our plans have been approved by the Illinois Air Pollution Control Board to meet its standards for particulates. These plans include installation of electrostatic precipitators, along with other steps. Over the next five years we expect to spend some $16 million on this program.

Technology has not yet been developed to eliminate sulphur oxides from stack emissions. To hasten such development, we are taking part in various studies and research projects and are following with interest the work of others. We are also studying the availability, cost, and feasibility of other fuels.

The Illinois Commerce Commission, by which our Company is regulated, is conducting an investigation of air pollution by electric utility companies in the state. We have appeared at its hearings and expect to be called upon for additional data and testimony.

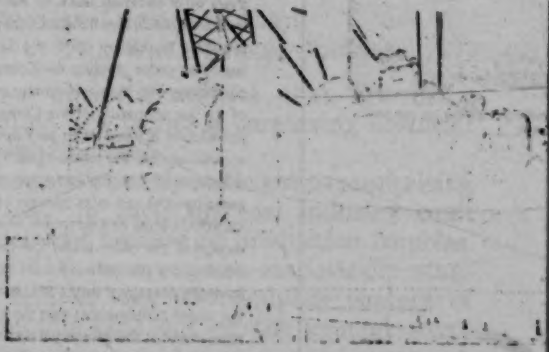
At this point—with standards, regulations, and technology all in a period of change and formation—there is no basis for any accurate



estimation of the eventual cost to our Company and our customers of doing our part in cleaning up the air.

INTERCONNECTIONS

Our Company, Central Illinois Public Service Company, and Union Electric Company entered into a contract in November, 1969, with Tennessee Valley Authority providing for new interconnection facilities between the systems of the three companies and TVA. The



A dual-fuel peaking unit turbine is pictured being placed in the Granite City area near Stallings, where four units will produce 100,000 kilowatts of power.

contract provides for the exchange of firm quantities of diversity power on a seasonal basis between TVA and the three companies as well as other operating benefits. Under the contract, Illinois Power will provide 65,000 kilowatts of capacity to TVA during the winter seasons when we expect to have excess capacity, and TVA will make available to the Company 65,000 kilowatts of capacity during our peak summer seasons when TVA expects to have excess capacity. This arrangement begins in November of 1972.

Union Electric has notified our Company and Central Illinois Public Service Company of the termination of the interconnection agreement under which the Illinois-Missouri Pool has operated since 1952. Termination of the contract becomes effective April 1, 1972. Prior to that time, new interchange agreements will be negotiated between the companies which will provide benefits similar to those in the present agreement.

Workmen installing gas regulator station.

Our Company has other interconnection agreements with the American Electric Power system, Commonwealth Edison Company, Central Illinois Light Company, Iowa-Illinois Gas and Electric Company, and Electric Energy, Inc.

CIPS ACQUISITION

On March 28, 1968, the Company and Central Illinois Public Service Company announced a proposal to offer to exchange .65 of a share of IP common stock for each share of common stock of CIPS. In March, 1969, the Illinois Commerce Commission approved the proposal. In January, 1970, the Securities and Exchange Commission issued an order granting the Company's application subject to conditions—(1) that appropriate provision be made for the divestment of the gas properties of the Company and CIPS and (2) that jurisdiction is reserved to pass upon the fairness of the terms of the acquisition and the terms of such divestment. Neither company will proceed with the exchange offer unless the divestment of the gas properties can in its opinion be accomplished without injury to its stockholders or customers. Studies undertaken prior to the receipt of the order under the then known possibilities did not develop any plan which would not result in such injury. The following footnote contained in the SEC findings and opinion accompanying the order contemplates that the acquisition of the CIPS stock and divestment of the gas properties may be accomplished on such a basis:

> "The companies may appropriately determine the nature and timing of any steps to be taken with respect to the acquisition of CIPS stock and the divestment of the gas properties in light of pertinent financial and money-market conditions. The reasonable flexibility available to the companies would thus not foreclose the selection of a program entailing more than one stage in the interests of feasibility and fairness to all concerned."

However, the determination of whether such a result can be accomplished will require further study by both companies. If this appears possible, further proceedings before the SEC and the Illinois Commerce Commission and acceptance or approval of stockholders of both companies will be required.

The SEC denied a contention of certain holders of CIPS preferred stock that the approval of the application should be conditioned on the elimination of the CIPS preferred.

Shortage of Low-Sulphur Coal Hampers Electric Utilities in Antipollution Efforts

By THOMAS LINDLEY EHRICH
Staff Reporter of THE WALL STREET JOURNAL

PITTSBURGH — Electric utilities that are being pressed to cut pollution are facing a perplexing obstacle: A shortage of low-sulphur coal.

Developed reserves aren't nearly sufficient to meet rising demand from utilities. In fact, the coal industry can't even meet present demand because of production troubles. And while potential U.S. reserves are statistically staggering—some 1.02 trillion tons with sulphur content of 1% or less—getting this coal out of the ground won't be done easily or soon.

Nor will it come cheaply. Mining executives estimate that low-sulphur coal, if it ever becomes widely available for utility use, will cost as much as 50% more than medium and high-sulphur coals. This is due to expensive mining conditions generally associated with low-sulphur coal, plus the big expense of opening new mines. The price could go even higher if utilities are forced to bid against the steel industry, the prime user of low-sulphur coal.

Such cost and availability problems will directly affect pollution-control planning by many utilities, particularly the coal-burning plants that provide more than half the nation's electricity. These utilities are in the process of deciding how to meet stringent curbs on sulphur dioxide emissions, and many hope to switch to low-sulphur coal.

Difficulties in making such a switch could encourage some utilities to drop coal entirely, moving to low-sulfur fuel oil, to sulphur-free fuels such as natural gas or to increased reliance on nuclear power. The coal industry, however, hopes utilities will install stack-gas cleaning

devices, thus permitting continued use of medium and high-sulphur coals.

Less than one-quarter of the coal burned by electric utilities these days is low-sulphur coal. (Low-sulphur generally means sulphur content of 1% or less, though some states are setting a 1.5% limit.) Sulphur content of the rest ranges up to about 6%, with the bulk of utility coal use in the 1.6% to 3.5% range. In recent years, use of coal toward the top end of the sulphur-content scales has increased due to improvements in furnace efficiency.

Moving out of this coal-buying pattern couldn't be done in the current market. Nowadays, mine output is committed under long-term contract. Existing mines are operating at capacity, so new mines would be needed to meet increased utility demand. (For the moment, at least, steelmakers have the inside track on new supplies of low-sulphur coal. Reserve stockpiles at U.S. mills are dangerously low due to coal production shortfalls the past two years, and foreign steel companies are starting to bid aggressively for U.S. coal.)

Less than one-fourth of known U.S. low-sulphur coal reserves is the bituminous coal burned by nearly all coal-fired steam plants. Some 78% of the total represents subbituminous coal and lignite, grades that couldn't be used in the bituminous-fired plants without expensive boiler alterations.

The 21% that is bituminous coal isn't an insignificant amount, of course. These 215 billion tons could last for centuries. But the need and supply don't mesh. Some 90% of utility coal use is east of the Mississippi. The biggest and most easily mined reserves lie in Colorado, Utah and Wyoming. Freight costs from there to Midwestern utilities would be twice the current charges for shipment from Midwestern mines.

Low-sulphur reserves in the Eastern coal states amount to an ample 82 billion tons or 38% of the total bituminous low-sulphur reserves. Coal men, however, say the best Eastern deposits are owned or controlled by steel producers for their own use and the rest lies in thin, hard-to-mine seams. "There isn't enough left to make a real

dent in the utility market," says John Corcoran, president of Consolidation Coal Co., a subsidiary of Continental Oil Co. Says another coal man: "When you're talking thin seams, you're doubling the cost."

Another problem is the health of the coal industry. Demand is strong now, but a sizable portion of the industry—the hundreds of small and medium-sized operators—would be endangered by wholesale switches from medium and high-sulphur coals. These smaller firms probably would go out of business, industry observers say. Even big operators would be hard pressed to finance the heavy capital investment involved in constructing new mines. Some already are asking customers to help finance mine construction.

For this reason, coal industry spokesmen are urging utilities to invest in sulphur-dioxide removal systems. At the same time, coal executives are urging regulatory agencies to go slow on enforcing strict pollution-control rules.

Even if low-sulphur coal is to be mined, it will be costly. Coal men are estimating prices as high as 40 cents per million BTUs, compared with 21 cents to 26 cents for high-sulphur coal now being burned. (BTU, for British thermal unit, is a measure of heat. Coal and other fuels usually are priced according to heat content, not according to tons or barrels).

Utilities might well be willing to pay such prices, of course. Utilities in the Great Lakes are paying 45 cents per million BTUs for imported low-sulphur fuel oil and as much as 60 cents for domestic oil. But in the long run, coal at such prices probably would cease to be competitive with nuclear power, currently rated at 28 cents to 30 cents per million BTUs, and with imported fuel oil if import rules are eased as some utilities are seeking.

Also, coal men say a good many coal-fired plants couldn't switch to low-sulphur coals without costly changes. One industry spokesman estimates 85% of the coal plants in New Jersey, for example, "couldn't use it without major furnace revisions." The reason is that most coal-fired plants are designed to burn a certain

type of coal, often from a particular region of the coal-fields. (The New Jersey plants burn coal from the Fairmont, W. Va., area.)

Long-range developments could alter the picture greatly. The Western coals, for example, won't always be inaccessible. Several Midwest utilities are starting to buy in Wyoming, hauling the coal in multicar, fast-loading "unit trains," which cut freight costs substantially.

Another possibility is shipping the electricity instead of the coal. Utilities would build steam plants at the Western mines, and then use extra-high-voltage transmission cables to send electricity to users. Use of this technique is considered imminent, both out West and in the more remote sections of the Eastern coal-fields. Presently, the cost of extra-high-voltage transmission is quite high.

Also, some utilities are starting to build plants designed to use the plentiful lignite and subbituminous coals.

MARVIN O. YOUNG
VICE PRESIDENT AND GENERAL COUNSEL

April 1, 1970

Mr. Reuben Hedlund
Kirkland, Ellis, Hodson,
Chaffetz & Masters
Prudential Plaza
Chicago, Illinois 60601

RE: United States v. General Dynamics Corporation et al., Civil Action No. 67 C 1632 (N.D.Ill.)

Dear Mr. Hedlund:

Pursuant to your telephone request of today concerning certain coal reserves owned by Peabody in McDonough, Schuyler, Adams, Brown and Hancock Counties, Illinois, I would like to advise you as follows:

Peabody acquired some coal reserves in these counties during the period 1958 through 1960 by way of leases. The leases on coal reserves in Brown County, Illinois have been dropped.

Since the early part of 1961 Peabody has not attempted to acquire any further coal reserves in these Counties and has no plans at the present time to develop any of these reserves because the tonnage involved is so small that it would be economically impossible to mine such reserves.

Very truly yours,

Marvin O. Young

WESTERN UNION
SENDING BLANK

CALL LETTERS FBJ DLPD 3/5/70 CHARGE TO National Coal Association
Washington, D. C.

DEFENDANT'S EXHIBIT 238

The President
The White House
Washington, D. C.

Page 1 of 3 pages

The Wall Street Journal of today (article by Burt Schorr, page 14) reports that the Oil Import Board of Appeals has decided to open the Midwest to foreign residual oil. If so, this Nation is threatened with dire future consequences. We can have both clean air and reliable electricity, only by using domestic coal with techniques now available for the removal of sulphur dioxide from stack gas. The manufacturers of sulphur removal equipment will guarantee performance, and indications are that the cost will be no greater

WESTERN UNION
SENDING BLANK

CALL LETTERS FBJ DLPD CHARGE TO

The President Page 2 of 3 pages

than the cost of using foreign oil.

Unfortunately, the electric utilities are more inclined to comply with clean air regulations by switching to foreign oil. If they are permitted to do this, the domestic coal industry will suffer. But far more important, the entire national security will be endangered, because it will lead eventually to very heavy dependence on energy sources which are unreliable because of problems in Mid-East and other sources and because of possible interruptions in transportation over great distances. In addition, the government will be afflicted with a serious drain on our balance of

WESTERN UNION
SENDING BLANK

CALL LETTERS FBJ DLPD CHARGE TO

The President Page 3 of 3 pages

payments.

The Nation can and should have clean air and reliable energy. We hope you will do whatever you can to see that the utilities build sulphur removal facilities which will permit use of our most abundant energy source rather than switch to foreign oil. To this end, existing limitations on foreign oil imports to the Midwest should be retained.

Stephen Dunn, President

~~1931~~ 1921

DEFENDANT'S EXHIBIT 239

PROPOSED PLANS OF COMPLIANCE WITH CHICAGO AIR POLLUTION CONTROL ORDINANCE OF THOSE FACILITIES FOR WHICH A RESPONSE TO COURT-ORDERED SUBPOENA QUESTIONNAIRE WAS RECEIVED

There are forty facilities [excluding Commonwealth Edison generating stations] which are located within the Metropolitan Chicago Interstate Air Quality Control Region, as designated 42 C.F.R. §81.14, and for which a response to the Court-Ordered Subpoena Questionnaire was received. [See Table D-P of Defendants' Exhibit No. 55].

Of these forty facilities, the following ten are located inside the City of Chicago:

	Company & Facility		1967 Total Coal Consumed 1/
1.	Campbell Soup		Less than 20,000 tons
2.	Celotex Corporation		22,000 tons
3.	Central Soya-Chemurgy Division		65,000 tons
4.	Container Corporation	- Water Street	23,000 tons
5.	Container Corporation	- Ogden Avenue	20,000 tons
6.	Darling, Inc.	- Ashland Avenue	34,000 tons
7.	Darling, Inc.	- West 46th Street	60,000 tons
8.	Interlake Steel	- Torrance Avenue	395,000 tons
9.	International Harvester	- Wisconsin Steel Division	25,000 tons
10.	International Harvester	- Tractor Division	21,000 tons
11.	Proctor & Gamble		60,000 tons
12.	Sherwin Williams		23,000 tons
13.	Swift & Company		28,000 tons

TOTAL: 10 companies; 13 facilities; over 776,000 tons of coal

The above facilities are subject to Section 17-25(3)(a) of the Municipal Code of Chicago, as amended by Ordinance of June 23, 1969 [Journal of the City Council, pp. 5618-5619] 2/ and are subject to the jurisdiction of the Chicago Department of Environmental Control.

1/ Source: The respective Form 150 responses of the companies set forth above.

2/ An excerpt of this provision is attached hereto as an Appendix.

That agency sent out a questionnaire in October of 1969 to the approximately 2,500 industrial facilities in Chicago which burn fuel (oil, gas or coal) at a rate of 288,000 BTU per hour on an annual average. The purpose of this inquiry was to obtain from the recipients the manner or plan of compliance with §17-25(3)(a) proposed for these facilities.

As a follow-up to the Court-Ordered Subpoena Questionnaire, the following is a summary of the responses to the Department of Environmental Control inquiry for those facilities for which a subpoena response was also received.

Group I. Two of the above facilities burn low sulphur Southern Illinois metallurgical coal for the purpose of coking. This coal has a sulphur content of less than 1.3% and falls well below the Ordinance requirement.
1967 tonnage represented: 420,000 tons.

Group II. Of the remaining 11 facilities, 2 did not respond to the Department of Environmental Control inquiry.
1967 tonnage represented: 50,000 tons.

Group III. Of the remaining 9 facilities:

A. 6 facilities have converted, or will convert during the year 1970, all coal-burning boilers to use gas, low sulphur #6 oil or a combination of both.
1967 tonnage represented: 179,000 tons.

(1) 1 of these 6 has converted to natural gas/low sulphur oil but may need to burn a small amount of low sulphur (less than 2.5%) coal for emergency use.

(2) 4 of these 6 have converted coal-burning units to oil and gas units and are burning no coal whatsoever.

(3) 1 of these 6 is burning natural gas on an interruptible basis until mid-1970, at which time it will have converted its combustion units to the use of #6 (low sulphur) oil.

B. 2 facilities will continue to burn coal in the boilers but will burn coal of less than 2.5% sulphur content.
1967 tonnage represented: 81,000 tons.

C. 1 of the above group will convert to the equal use of gas and oil by October of 1970. After such conversion, this facility also intends to continue to burn high sulphur coal in a quantity which is one-third its present coal consumption rate.
1967 tonnage represented: 65,000 tons.

The respondent for this facility stated that two coal suppliers had informed it that there would ~~be~~ not be available to the respondent coal with a sulfur content of less than 2.5%.

RE: U.S. vs. General Dynamics Corporation et al.,
Civil Action No. 67 C 1632 (N.D. Ill.)

Gentlemen:

This will reply to your letter of January 10, 1969 requesting additional information relative to the above-captioned case.

During the period 1964 through 1967 this company used, at the St. Louis, Missouri and LaSalle, Illinois plants, for the purpose for which coal is required, the below listed quantities of gas at the costs as reflected:

	ST. LOUIS		LA SALLE	
	Cu. Ft.	Amount	Cu. Ft.	Amount
1964	1,464,302,000	$334,215	-	$ -
1965	1,861,883,000	400,266	-	-
1966	1,620,065,000	348,314	290,760,200	91,360
1967	1,634,518,000	364,471	384,321,100	109,356

It has been our usual practice to consume gas at the St. Louis plant during the approximate period April 1 to October 31 of each year as an economically advantageous rate structure is available to the company during that period.

DEPARTMENT OF JUSTICE
JAN 24 1969
DIVISION OF INVESTIGATION

SHEET NO. 2 ALPHA PORTLAND CEMENT CO.

TO Department of Justice January 22, 1969

The use of gas at the LaSalle plant was commenced in 1966 to permit the economic evaluation of such fuel as an alternative to coal as well as to permit the repair and rebuilding of coal preparation equipment at that plant.

Very truly yours,

REH/fm

DIVISION OF RECORDS

Re: United States v. General Dynamics Corporation et al., Civil Action No. 67 C 1632 (N.D. Ill.)
60-0-37-920

Dear Mr. Cusack:

This is in reply to your letter of April 9 addressed to Mr. C. F. John requesting information in regard to the above referenced civil action.

The information requested in paragraphs 1 and 2 of your letter is detailed in Tables I and II attached. All coal purchased for the following generating stations for the years 1964 through 1967 was delivered to storage docks by lake vessels during the navigation season for Lake Michigan, which normally extends from April 1 to December 1 each year:

Oak Creek Power Plant
Port Washington Power Plant
Commerce Street Power Plant
East Wells Street Power Plant

This coal was consumed approximately from mid-April of the year in which it was delivered to mid-April of the following year. Coal purchased for use at our Lakeside Power Plant for the same years was consumed during the calendar year in which it was purchased. The footnote : of Tables I and II explain the variance in the period coal was purchased and consumed.

In response to your paragraph 3, during the referenced period facilities for generating electricity by utilizing oil and gas were available at the Commerce Street Power Plant. Details in regard to gas and oil consumption are given in Table III attached. Boiler #25 of this plant is the only unit so equipped and was equipped to burn gas or oil exclusively since November, 1964. This unit has a capability of 22,000 kw

when supplying 230,000 lbs. per hour of steam for our heating utility. The footnotes to Table III explain the seasonal usage of gas and oil and the portion of each used for steam production at this plant.

In response to paragraph 4, no facilities were available for generating electricity by nuclear energy through the years 1964 through 1967.

Facilities for generating electricity from other sources as requested in paragraph 5 are limited to hydroelectric and diesel plants of Wisconsin Michigan Power Company, a wholly owned subsidiary of Wisconsin Electric Power Company. The information which you requested regarding these facilities is given in Table IV attached.

Data in response to paragraph 6 of your letter are not available.

You will note from the several documents attached that the majority of our coal is derived from mines in Illinois and western Kentucky. We believe that the acquisition by General Dynamics Corporation of the United Electric Coal Companies made it possible for the latter companies to have available financial resources for the development of mining properties and to increase the availability of coal sources from these regions.

You may wish to correct your records to indicate that Mr. C. F. John retired as Vice President in Charge of Power on December 31, 1965.

Very truly yours,

Robert H. Gorske

Robert H. Gorske General Counsel

Dear Mr. Hedlund:

In regard to the United States v. General Dynamics litigation, it is my understanding that the Department of Justice has introduced into evidence an excerpt of the 1951 study made by the Paul Weir Company under subcontract to the United States Army Corps of Engineers. Apparently, the excerpt in question, entitled "Coal Data Sheets Showing Recoverable Coal Reserves In Illinois Available For Commercial Use And Synthetic Liquid Fuels Manufacture", has been designated Government Exhibit No. 308 and has been introduced to place in issue the estimated "Recoverable Strip Coal Reserves" in Illinois contained therein. It is the position of the Paul Weir Company that the conclusions relating to Illinois strip reserves reached in that report were valid ones, when viewed in light of the parameters of that report and the limitations inherent in the underlying data at that time. It is the purpose of this letter to delineate these matters so that the summary report offered into evidence may be viewed in its proper context.

First, the survey made for the Corps of Engineers was national in scope and included information on four raw materials, only one of which was coal. The Paul Weir Company received the coal subcontract from the prime contractor, Ford, Bacon & Davis. We collected information on coal deposits in 24 states. The Illinois report, from which GX No. 308 is taken, is contained in two main volumes and one supplement.

The excerpt which constitutes the trial exhibit is only one part of the supplementary volume, which also contains detailed statistical charts and tables on a township by township basis. Thus, it can be readily seen that the brief excerpt submitted into evidence is but a small portion of the published material concerning Illinois coal made by Paul Weir Company for this study.

Secondly, our performance under the terms of the subcontract was confined to a study of information obtainable from then-existing published material, and there was no authorization for any field studies or primary research. Thus, the sources for our report and its conclusions were eclectic in nature. It is our belief that this report was the first such comprehensive digest of existing data on coal reserves in the State of Illinois. This report was completed two years before the principal reserve study of the Illinois Geological Survey was undertaken; and, of course, the definitive survey of Illinois strip reserves made by the IGS was not commenced until 1957, seven years after the publication date of the report in question. In 1950, the only published materials which pertained exclusively to Illinois strip reserves and which were available for our use were two Illinois Geological Survey reports, published in 1926 and 1929 respectively, which reported the occurrence of strip coal in two very localized areas of the state and a series of reconnaissance maps prepared by the Department of Agriculture in 1946 and 1947.

Thirdly, in addition to technological innovations and developments in the strip mining industry, the development of more precise and accurate information-gathering techniques in the last twenty years also accounts for the discrepancy between our 1951 recoverable strip reserve estimate and an equivalent figure of today. For example, at that time, all geological maps were charted on about a one" to one mile scale and at a 15 minute quadrangle variant. In contrast, maps drawn on a one":2000' scale and on a 7-1/2 minute quadrangle variant are available today. Such breakthroughs in data collection increased the body of knowledge of coal

reserves substantially and necessarily make more precise estimates based thereon. Such an increment in accumulated data specifically enhance the reliability of strip coal reserve estimates. As was stated at page 57 of Volume I of the 1951 report, "In estimating strippable reserves, the amount and character of the available information are relatively much more important than in estimating underground reserves, because of the determinative interdependence of factors, such as the thickness and continuity of coal bed and the thickness and character of overburden in a relatively small proportion of the general coal-bearing area."

Finally, the terms of our subcontract set definitional limits as to what reserves were to be considered "strippable." Although this provision established the maximum depth for "strip reserves," the contract anticipated the problems inherent in reaching conclusions based upon derivative sources of information and provided that reserves lesser in depth could be defined as "underground coal" in the judgment of the subcontractor. Accordingly, commensurate with the degree of reliability of the given underlying data and the purpose of the assignment, Paul Weir Company classified some reserves as "deep" rather than "strip," when information on intermediate categories of deposits was insufficient.

When the above-mentioned facts are taken into consideration, we feel that the 1951 estimate is consistent with the purposes of the assignment undertaken by the Paul Weir Company and that comparisons between its conclusions and contemporary knowledge are meaningless.

Sincerely,

Clayton G. Ball

Clayton G. Ball
Chairman of the Board
Paul Weir Company

ABATEMENT OF SULFUR OXIDE EMISSIONS FROM STATIONARY COMBUSTION SOURCES

Prepared by
Ad Hoc Panel on Control of Sulfur Dioxide from Stationary Combustion Sources
Committee on Air Quality Management
Committees on Pollution Abatement and Control
Division of Engineering
National Research Council

Washington, D.C.
1970

This is the report of a study undertaken by the Committee on Air Quality Management *Ad Hoc* Panel on Control of Sulfur Oxide from Stationary Combustion Sources for the National Academy of Engineering in execution of work under Contract No. CPA 22-69-31 with the National Air Pollution Control Administration, Consumer Protection and Environmental Health Service, Public Health Service, U.S. Department of Health, Education, and Welfare.

As a part of the Division of Engineering of the National Research Council, the Committees on Pollution Abatement and Control perform study, evaluation, or advisory functions through groups composed of individuals selected from academic, governmental, and industrial sources for their competence and interest in the subject under consideration. Members of these groups serve as individuals contributing their personal knowledge and judgments and not as representatives of any organization in which they are employed or with which they may be associated.

PREFACE

Because the air, water, and land on earth are limited, we, as a nation, must plan and work together to ensure the preservation of an acceptable environment. In this report of a study on the control of sulfur oxide emissions into the atmosphere, primarily from electricity generating stations, an effort has been made to place the findings of the study in perspective with the entire problem of environmental quality management.

On the basis of problem definition, a study of need, a study of engineering constraints, and an analysis of technological requirements and alternatives, this report outlines a government-industry program for research, development, and demonstration of potential control processes.

No attempt has been made, however, to deal with such problems of sulfur oxide emissions as their effect on health and other biological aspects. Important though such studies may be, they are outside the scope of the *Ad Hoc* Panel on Control of Sulfur Oxide from Stationary Combustion Sources.

The members of the panel, along with the members of the Committee on Air Quality Management, share the objectives of the Congress as representing the determination of the people to restore and maintain the quality of our air resources and the objectives of the National Air Pollution Control Administration of the Department of Health, Education, and Welfare as the Federal "lead agency" to assure significant progress by an early date. The panel hopes that the results of its study will be useful in the attainment of these objectives.

The panel's estimation of the present status of sulfur control technology is based primarily on presentations by 23 research and industrial organizations that came to Washington to discuss the results of their process studies and their proposals for further

work. In addition, 23 other organizations provided information by correspondence.

The panel appreciates the cooperation received from industrial and research organizations with active programs in sulfur oxide control. The panel is particularly grateful to Mr. Paul W. Spaite, Director, Bureau of Engineering and Physical Sciences, National Air Pollution Control Administration, and his staff for their outstanding support.

A summary of the study and a brief statement of conclusions are presented first in the report for the benefit of those who may wish to gain an overview of the panel's efforts. These are followed by an introduction covering the background of the study, the roles of the National Academy of Sciences and the National Academy of Engineering, and the nature of the sulfur oxide emissions problem. The remaining sections of the report cover the impact of the nation's growing requirements for electricity upon the sulfur oxide emissions problem and review the possibilities for abatement of sulfur oxide emissions through the widespread use of nuclear power plants, the use of sulfur-free or low-sulfur fuels, and the development and application of technology to control sulfur oxide emissions. A strategy for the research, development, and demonstration of this technology is presented.

Appendixes to the report contain lists of organizations that made presentations and correspondents who supplied information for the study, lists of research and development activities in sulfur oxide pollution control in the United States and abroad, and a selective bibliography.

It is hoped this report will provide a basis for increased governmental and public understanding of the problems of sulfur oxide abatement and control, and will direct attention and adequate assignment of resources to the orderly and expeditious solution of this portion of the nation's problems of environmental quality management.

SUMMARY AND CONCLUSIONS

Controlling and improving the quality of our environmental resources is a growing concern of the nation. National and regional goals and standards for air quality management are being defined. Capital investments of billions of dollars will be required to install processes to meet these standards. Keeping these costs within bounds, while still attaining an acceptable level of control within the shortest practical period of time, will call for the best efforts and most careful planning at all levels from individuals, civic groups, and companies through local, regional, state, and Federal agencies.

The emission of SO_2* from combustion of sulfur-bearing coal and oil, primarily for the generation of electrical energy, is second only to the emission of pollutants from internal combustion engines in quantity of pollutants discharged to the national air environment.

During the next 20 years, the national requirement for electrical energy is expected to more than triple. The supply of natural gas, a low-sulfur fuel, is expected to decrease in about 10 years, and petroleum products may reach their maximum availability in about 30 years. To supply the needed electricity, the use of coal is expected to triple by the year 2000, when it is expected that the use of nuclear energy will about equal the use of coal, after which the requirement for coal will start a downward trend.

The substitution of low-sulfur fuels, the only presently available method for reducing SO_2 emissions, is restricted by the limited availability

---

*The symbol SO_2 is used in this report to designate the sulfur oxides in stack gases (SO_2 plus 1 percent to 2 percent of SO_3).

of natural gas, low-sulfur oil, and low-sulfur coal. More rapid expansion of the application of nuclear energy is constrained by engineering and economic problems, in addition to siting problems, that are of growing concern to all planning of major electricity generating installations. By the late 1980's, new fossil-fueled plants may employ magnetohydrodynamic (MHD) generators, followed by conventional steam boilers or by advanced Brayton or Rankine power cycles. The combined energy conversion efficiency of such plants is expected to be in the range of 50 percent to 60 percent compared with about 40 percent for conventional plants, which would result in a corresponding decrease in SO_2 emissions. However, the high operating temperature of MHD units may result in increased NO_x emissions.

In addition to improving the energy conversion efficiency, the fast breeder nuclear reactor produces a net gain of fissionable material and thereby reduces the net cost of fuel. The Atomic Energy Commission is planning a 500 MW fast breeder demonstration plant for 1976 and expects the first commercial units to start up about 1985 in the United States.

Therefore, *the reduction of SO_2 emissions from stationary combustion sources, in the next 5 to 20 years, will depend very largely on the development, demonstration, and application of a combination of technologies designed to prevent the sulfur in coal and petroleum products from reaching the atmosphere through the combustion processes.*

The technology for removal of sulfur from oil is being developed by a number of oil companies, and the panel does not believe that NAPCA should contribute significantly to these developments.

Although broader application and refinement of existing technology could increase the quantity of low-sulfur coal available, there are no cleaning or washing processes presently in sight that have the potential for substantially reducing sulfur content below levels presently being achieved. This emphasizes

the need for new concepts in engineering and chemical approaches to the desulfurization of coal.

In addition to joint support by groups of utilities, a number of industrial organizations have committed significant funds to research, development, and demonstration of sulfur emission control processes and equipment. An increase in these activities, together with increased support by the Federal Government, is needed.

The panel reviewed the status of United States and foreign sulfur oxide abatement and control processes and firmly concluded that, *contrary to widely held belief, commercially proven technology for control of sulfur oxides from combustion processes does not exist.*

Efforts to force the broad-scale installation of unproven processes would be unwise; the operating risks are too great to justify such action, and there is a real danger that such efforts would, in the end, delay effective SO_2 emission control. *A high level of government support is needed for several years to encourage research, engineering development, and demonstration of a variety of the more promising processes, as may be suited to specific local and regional conditions, to bring these processes to full-scale operating efficiency at the earliest practical date. This can be done most expeditiously if Federal support, in addition to industry commitments, is provided at the appropriate time and in the needed amounts.*

Federal support for the development of the following control approaches is suggested:

1. "Throw-away" processes for removal of SO_2 from stack gases, such as limestone injection, which produce a presently nonmarketable product

2. New combustion concepts, such as fluidized bed combustion (FBC), which fixes the sulfur as a sulfate during combus-

tion and prevents its release as SO_2 to the stack

3. Chemical recovery processes, which produce salable SO_2, sulfuric acid, elemental sulfur, or fertilizers

4. Coal gasification processes, which produce sulfur-free fuels

5. New concepts in engineering and chemical approaches to the desulfurization of coal

The limestone injection processes, with adequate particulate control, should be commercially demonstrated within the next 1 to 3 years and, if successful, can be installed in many existing plants.

Several sulfur-recovery processes appear to be ready for scale-up to commercial demonstration size (100,000 kW or larger boilers). Full-scale demonstration of the industrial reliability of these processes is 4 to 10 years away. Some of them can be installed in a portion of existing plants or engineered into future plants.

New combustion technology may be available for industrial application in 5 to 10 years. Efficient coal gasification processes, which are 5 to 10 years away, have the potential for producing pipeline-quality, low-sulfur gas for supplementing existing supplies of natural gas or for producing a product of less than pipeline-quality, but adequate for power generation. Such fuels seem likely to become increasingly competitive for use in power production as the cost for controlling all pollutants (SO_2, NO_x, and fine particulates) increases the costs for conventional systems.

These time estimates are realistic only if there is dedication and a positive commitment on the part of government agencies, utilities, fuel suppliers, and equipment manufacturers to support the orderly

development and timely application of the more promising processes.

In recommending a 5-year plan for future work, the panel places special emphasis on the following:

1. Complete development of the limestone process should be given high priority because it is applicable to many existing boilers and is closer than others to demonstrated industrial application.

2. For new power plants and some existing plants, it is expected that sulfur-recovery processes will be necessary to keep costs for future control within reasonable limits.

3. NAPCA should continue to support the development and demonstration of new concepts in combustion technology, sulfur-recovery, and coal-desulfurization processes.

4. Research should be supported on ways to combine the abatement of nitrogen oxide and particulates with sulfur oxide control.

5. Elemental sulfur is a more desirable by-product than sulfuric acid or sulfur dioxide. The conversion of sulfur dioxide to sulfur is not a well established process, and it is important that the technology and costs of this conversion be thoroughly studied.

6. NAPCA should employ a *process engineering and construction firm* to project costs on a *common basis* for all the promising processes at various stages in their development to aid in making scale-up decisions.

II

INTRODUCTION

A. BACKGROUND OF THE STUDY

The concern of Americans for the deterioration of the nation's air resources is reflected in Public Law 90-148 as amended, the Air Quality Act of 1967, enacted by the 90th Congress on November 21, 1967. Responsibility for carrying out the provisions of the law is assigned to the Secretary of the Department of Health, Education, and Welfare.

The purposes of the Act are set forth in Section 101(b) as:

1. to protect and enhance the quality of the nation's air resources so as to promote the public health and welfare and the productive capacity of its population;

2. to initiate and accelerate a national research and development program to achieve the prevention and control of air pollution;

3. to provide technical and financial assistance to State and local governments in connection with the development and execution of their air pollution prevention and control programs; and

4. to encourage and assist the development and operation of regional air pollution control programs.

Special emphasis (Section 104) is given to research and development into new and improved methods for the prevention and control of air pollution resulting from the combustion of fuels. In addition to providing for laboratory and pilot plant testing, Section 104(a)(4) calls upon the Secretary of the Department of Health, Education, and Welfare to "con-

struct, operate, and maintain, or assist in meeting the cost of the construction, operation and maintenance of new or improved demonstration plants or processes which have promise of accomplishing the purposes of this Act."

The Clean Air Act recognizes the regional nature of air pollution problems. One of the functions of the Federal Government under the 1967 legislation is the designation of air quality control regions in all those areas in which air pollution constitutes a serious threat to health and welfare. Once air quality regions are designated, and NAPCA has issued criteria documents describing the harmful effects of specific pollutants, together with documents describing techniques for controlling the pollutants, it becomes the responsibility of the states in the regions to develop air quality standards and plans for enforcing them. In 1969, NAPCA issued criteria on two of the major pollutants--particulate matter and the sulfur oxides--together with the required supporting documents on techniques available for preventing and controlling their emission into the atmosphere. In March 1970, NAPCA issued air quality criteria and recommended control techniques for carbon monoxide, photochemical oxidants, and hydrocarbons.[16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26]*

The Clean Air Act, as amended, states in Section 101(a)(3) "that the prevention and control of air pollution at its source is the primary responsibility of State and local governments," in Section 101 (a)(4) "that Federal financial assistance and leadership is essential for the development of cooperative Federal, State, regional, and local programs to prevent and control air pollution," and, in Section 101 (b)(4), that a major purpose of the Act is "to encourage and assist the development and operation of regional air pollution control programs."

Federal assistance is provided in two major ways--financial and technical. Financial assistance

---

*Refer to numbered items in the bibliography contained in Appendix E of this report.

to air pollution control agencies is authorized under Section 105 of the Act. Under Section 106, financial assistance for planning for air quality standards and implementation plans in interstate air quality control regions is authorized.

The National Air Pollution Control Administration also provides technical assistance in conducting emission inventories, air quality monitoring and data analysis, and diffusion modeling. Diffusion modeling involves combining meteorological and emission data to predict air quality. These services are particularly helpful in attempting to test various emission reduction strategies.

The Air Quality Act of 1967 has created a new role for the Federal Government in air pollution control. The Act states that air quality standards that the states develop for an air quality control region become effective when the Secretary of the Department of Health, Education, and Welfare determines that such standards are "consistent with the air quality criteria," and it states that an implementation plan becomes effective when the Secretary determines "that the plan is consistent with the purposes of the Act insofar as it assures achieving such standards of air quality within a reasonable time."

What may be considered a "reasonable time" for attainment of an air quality standard will depend on a number of factors, including the availability of applicable control techniques and, particularly, the nature and seriousness of the adverse effects of the pollutants involved. Every implementation plan must include a timetable for reaching compliance with the projected requirements for the prevention, abatement, and control of air pollution. This timetable must provide for meaningful increments of progress over relatively short intervals, such as 1-year or 2-year periods, during the total timespan covered by the implementation plan.

B. THE ROLES OF THE NATIONAL ACADEMY OF SCIENCES AND THE NATIONAL ACADEMY OF ENGINEERING

The National Academy of Sciences and the National Academy of Engineering established the Environmental Studies Board in 1967 to coordinate activities of the two Academies in the environmental field. One of the first acts of this board was to create four committees within the Division of Engineering of the National Research Council on air, water, noise, and solid waste management, respectively. These committees have an engineering orientation and are available for advice and assistance to the Congress and to agencies of the executive branch having responsibility for pollution abatement and control. Needed interaction and coordination of the committees are provided through liaison activities of the Environmental Studies Board.

On June 20, 1969, the Department of Health, Education, and Welfare, through the National Air Pollution Control Administration, requested the National Academy of Engineering to make a comprehensive review of present industry and government research and development programs directed toward control of sulfur oxides effluents from stationary sources of combustion. The requested study would include technical and economic potentials, adequacy of scope, proper integration with other similar efforts, and the responsiveness to national needs.

The request was accepted after review and coordination by the Environmental Studies Board with other environmental activities of the National Academy of Engineering and the National Academy of Sciences. The task was assigned to the National Research Council's Committee on Air Quality Management, which in turn requested its *Ad Hoc* Panel on Control of Sulfur Oxide from Stationary Combustion Sources to carry out the study.

Because meeting national energy requirements is only one of man's activities that may result in unacceptable acceleration of environmental degradation, studies of abatement technology for other sources of SO_2 and other air pollutants will be made soon.

C. NATURE OF THE SULFUR OXIDE PROBLEM

At an early meeting of the panel with Dr. John T. Middleton, Commissioner of NAPCA, and subsequent meetings with Mr. Paul W. Spaite, Director of the Bureau of Engineering and Physical Sciences of NAPCA, and other members of the NAPCA staff, the panel was presented data on projected sulfur oxides emission with various levels of control. The panel members considered these data to be realistic, based on authoritative sources, and interpreted rationally and conservatively; and the members were impressed with the magnitude and urgency of the problem of sulfur oxides emission to the atmosphere. *The data and projections gave rise to the conclusion that positive action will be required to prevent the emission of sulfur oxides into the ambient air from more than quadrupling by the year 2000.*

The requirement for electrical power is projected to increase at an annual rate of 6 percent during the next 30 years. It is generally agreed that the generation and distribution of this quantity of electrical energy, using presently available fuels and technology, will result in unacceptable levels of environmental degradation. As previously noted, the use of sulfur-bearing fuels to generate electrical energy is only one of man's activities contributing to the decline in quality of our air resources, but it is a major source of SO_2.

NAPCA chose SO_2 emitted to the atmosphere from electricity generating plants for first attention because: (1) this is the largest man-made source of sulfur oxides; (2) it is widely dispersed nationally, but is largely concentrated in or near urban centers; (3) it is growing at about 6 percent per year; (4) it is intimately related to the national and international flow of energy resources; (5) it is important to regional economic development; and (6) it is critical to continued national well-being, security, and economic growth. Moreover, *while national and regional goals and standards are being defined, the processing methods presently available to attain these goals are inadequate for the task.*

Worldwide emission of sulfur into the atmosphere arises from biological, geological, and industrial activity.[11] Of the man-made sources, coal and oil combustion for electricity generation accounts for about 50 percent, other combustion of coal 16 percent, other combustion of oil 9 percent, primary and secondary smelting 12 percent, petroleum refining 7 percent; and miscellaneous sources including coke and sulfuric acid production, burning coal refuse banks, and refuse incineration 6 percent.

III

ENERGY REQUIREMENTS AND AIR POLLUTION CONTROL

A review of sulfur oxide abatement and control technology gives rise to concern as to the future supply of electricity and the future availability and use of fuels. There are important matters of policy and management regarding future energy conversion and consumption that bear directly and importantly on environmental problems, such as: emission of sulfur oxides, nitrogen oxides, particulates, carbon dioxide, carbon monoxide, and other pollutants from fossil fuels combustion; thermal pollution; siting of generating facilities and distribution systems; fuels policy and availability; radioactive pollution and disposal of radioactive wastes; and technological, political, jurisdictional, and economic limitations and constraints.

Electricity generation, sulfur oxide emission control, and other environmental factors are closely interrelated and require an integrated systems approach. The objective of providing for the nation's growing power needs is subject to the constraints of maintaining environmental quality, fuels availability, and technical developments. Within this framework lie the trade-offs of shifting generation, improved transmission, and the development of control processes. Overriding all of these is the long-term consequence of each alternative.

A. ELECTRICITY GENERATION

The Federal Power Commission now states that the 1970 requirement, including reasonable reserves, for electrical generating capacity is nearly 340 million kW. This requirement is expected to be nearly double by 1980 and to exceed 1 billion kW in 1990.

Figure 1 shows the electricity generation and fuels utilization forecast (assuming early development of the breeder reactor). At present, about 65 percent of the energy for electricity generation comes from coal, with natural gas and oil supplying most of the

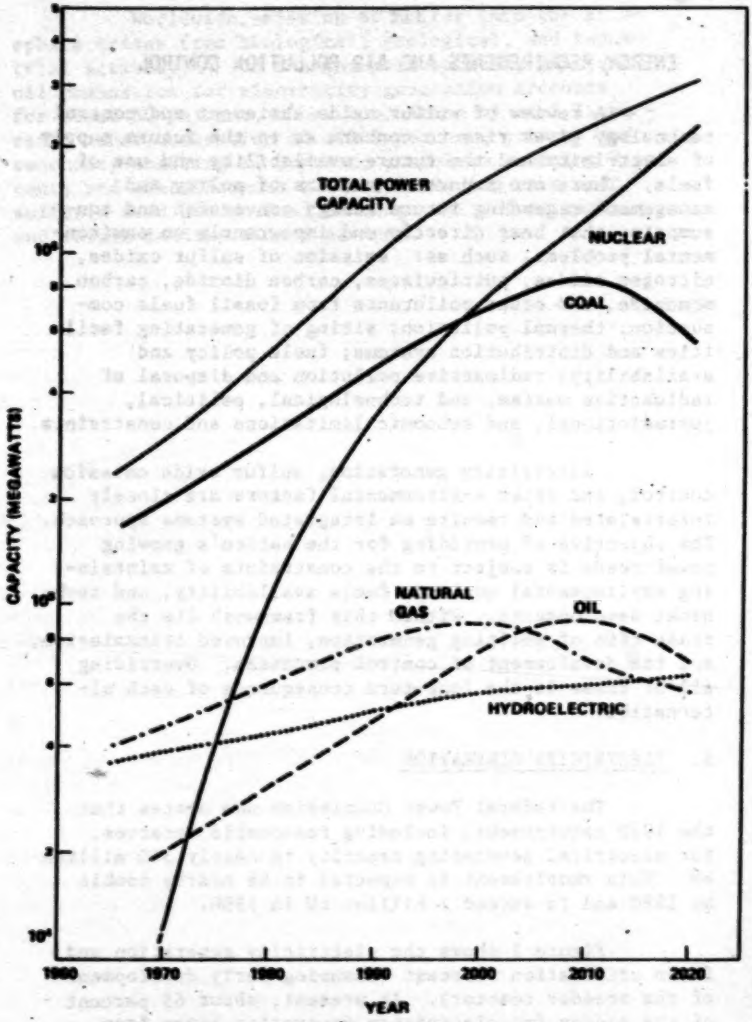

Figure 1. Projected power generating capacity and fuel sources of electric utilities in the United States (with breeder). NAPCA, February 1970.

remainder. It is predicted that the use of nuclear energy will increase rapidly and will exceed coal as an energy source around the year 2000. Because of the need to burn more coal to supply the needed power, sulfur emissions would be expected to increase more than fourfold by the year 2000, unless effective control processes are developed and applied.

Most of the new generating capacity installed between now and 1990 will be provided by some 250 large power plants of greater than 1,000 MW capacity.[2] The siting problem will generally be one of assuring that the relatively small number of large plants are adequately planned and located to meet the goals of providing low-cost, reliable power and minimizing the adverse effects on our environment. With an onsite investment of about $200 million to $400 million each, these new plants will be among the larger industrial establishments in the nation. Including support and auxiliary activities, they will represent approximately $80 billion of capital investment, which will be profoundly affected by the public interest.

B. SULFUR OXIDE EMISSIONS

The demand for electric power is increasing so rapidly that sulfur oxides emissions may increase even allowing for: (1) projected construction of nuclear power plants; (2) substitution of gas or low-sulfur fuel oil at locations where they are available; (3) use of coal of reduced sulfur content to the extent that can be expected; (4) introduction of improved combustion methods; and (5) application of improved stack-gas treatment and sulfur recovery processes.

Even with a national commitment to orderly but urgent plans for application of new technology, the best that can be hoped for through the year 2000 is a total sulfur oxides emission rate from all utilities somewhere near the present level. Near-term improvement in the quality of ambient air at ground level in urban areas may be brought about by resorting to dispersion of facilities, by use of tall stacks, or by load or fuel shifting under adverse meteorological

conditions. Sulfur oxides emission data and projections for the United States are shown in Table 1 and Figure 2.

Nuclear power plants emit no SO_2; essentially the same can be said for plants using natural gas. The technology for removal of sulfur from fuel oil appears to be reasonably well in hand. Further development of hydroelectric power will not be a major factor. The import of liquefied petroleum gases will most likely be increased to the limit of economic availability. Despite these factors, the use of coal will steadily increase and is projected to more than triple by the year 2000, before leveling off as large nuclear power stations replace those burning fossil fuels (Figure 1). About 75 percent of the sulfur oxides discharged into the atmosphere from man-made sources comes from the combustion of coal and oil. Gasoline contains almost no sulfur, so emissions from automobiles contribute little SO_2. But the combustion of coal, now averaging about 2.7 percent sulfur and forecast to increase to 3.5 percent by 2000, accounts for 65 percent of the total SO_2. The combustion of heavy fuel oil contributes about 12 percent.

TABLE 1

ESTIMATED POTENTIAL SULFUR DIOXIDE POLLUTION WITHOUT ABATEMENT[a]

UNITED STATES

	Annual Emission of Sulfur Dioxide (Millions of tons)				
	1967	1970	1980	1990	2000
Power plant operation (coal and oil)[b]	15.0	20.0	41.1	62.0	94.5
Other combustion of coal	5.1	4.8	4.0	3.1	1.6
Combustion of petroleum products (excluding power plant oil)	2.8	3.4	3.9	4.3	5.1
Smelting of metallic ores	3.8	4.0	5.3	7.1	9.6
Petroleum refinery operation	2.1	2.4	4.0	6.5	10.5

Total	30.8	36.6	60.9	86.4	125.8

(a) February 1970 estimates by National Air Pollution Control Administration, excluding transportation.
(b) See Figure 2. With breeder reactor.
(c) Includes coke processing, sulfuric acid plants, coal refuse banks, refuse incineration, and pulp and paper manufacturing.

Stack gases from fossil-fueled power plants contain about 1,000 to 3,000 ppm of SO_2, depending on the amount of sulfur in the fuel (1 ppm = 2860 $\mu g/m^3$ at standard conditions). Detrimental effects on vegeta-

tion, materials, and human health are first noticed in areas having 0.03 to 0.04 ppm (annual mean) SO_2 concentration.[5,14,15,20] Thus, a 100,000-fold dilution or reduction in concentration is required, on the average, by the time the SO_2 reaches ground level. SO_2 concentrations are near and, in some cases, at times above these levels in several urban areas of the United States.[20]

A number of SO_2 monitoring studies have been made near power plants, and there are various theoretical and computer models for predicting dispersion from stacks and resulting ground-level concentrations for different meteorological and topographic situations. These are intended to show the relation between stack emissions and the permissible concentrations.[20] Such studies have served as the basis for decisions to require use of fuels having lower sulfur content or the use of SO_2 emission control equipment.

The high dilution from stack level to ground level of SO_2 concentration will be required even with development of control devices. The most efficient removal processes can be expected to reduce stack gas concentrations of SO_2 by about 99 percent, which will result in an effluent that could still be above acceptable ground level concentrations. In addition to SO_2 dilution, tall stacks will be needed to disperse carbon dioxide, nitrogen oxide, and water vapor and to provide mixing with air to raise the oxygen content.

In some cases, the 1 percent sulfur limit in fuels has been found to be inadequate, and several regions are considering further reducing the permissible sulfur content. The New York-New Jersey Metropolitan region has set standards limiting sulfur to a maximum of 1.5 percent in fuels that are burned in existing power plants. Other regions are considering similar limits. Bituminous coal containing more than 1.0 percent sulfur cannot now be sold in New Jersey, and the limit will drop to 0.2 percent in October 1971. But the supply of less than 1.0 percent sulfur coal is limited; it appears that it would be impossible to provide the needed fuels if this standard were enforced across the country.

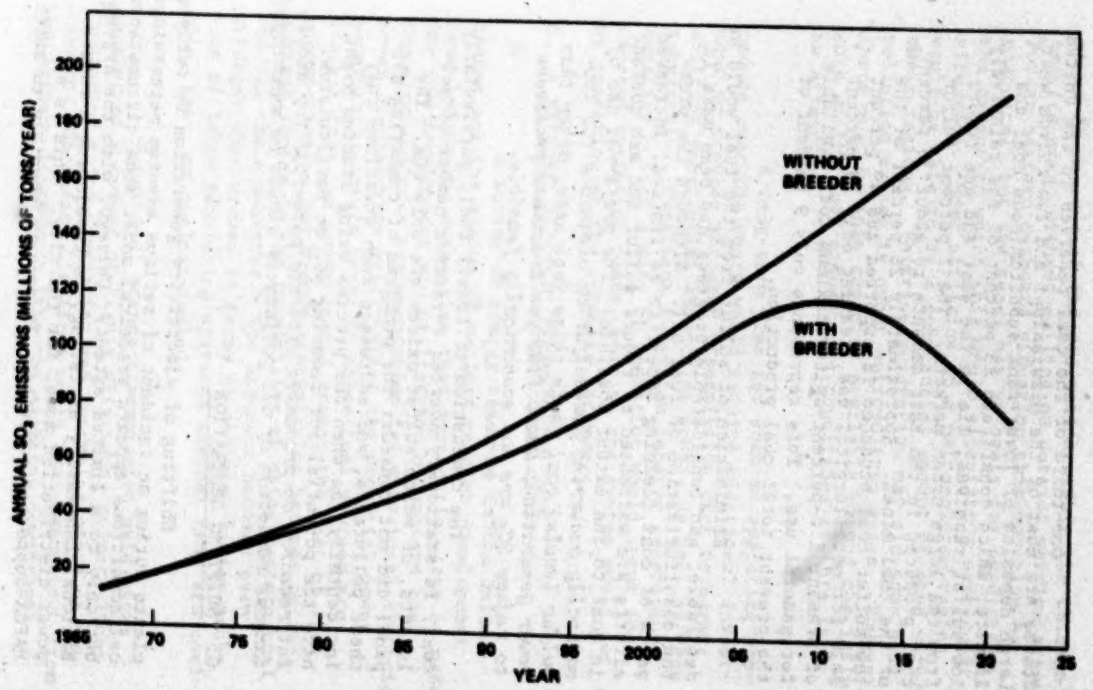

Figure 2. Comparison between projections for total power plant uncontrolled SO_2 emissions. NAPCA, February 1970.

One-third of the coal reserves in the United States are east of the Mississippi and two-thirds west. Large deposits of lower-rank subbituminous coal and lignite, which constitute 83 percent of the relatively low-sulfur reserves, lie in the West and are remote from the large urban markets. The 1 percent sulfur coal produced in the East amounts to about 36 percent of the coal mined. Approximately 26 percent of the low-sulfur coal produced is exported and 49 percent sold for metallurgical use, leaving only 25 percent of present 1.0-percent-sulfur-maximum coal available for general use. This represents only 9 percent of the present total coal production.

Elimination of sulfur from the fuel would be desirable, and considerable progress has been made in the desulfurization of fuel oil. Although the prospects of coal cleaning appear to be limited, increased efforts are warranted to reduce sulfur and ash content in coal to the extent possible. *The preferred use of naturally occurring low-sulfur or cleanable (to low-sulfur levels) coal is in those fuel uses, other than power generation, where flue gas treatment processes to reduce SO_2 are not economically feasible.*

The combustion of fossil fuel, particularly coal, in stationary sources creates a number of pollutants, of which sulfur oxides are only one. The panel did not consider the problems of combating all these pollutants, and addressed such questions only incidentally, as when the process being studied might have the potential for removing NO_x or particulates. But, *research on processes with the potential for simultaneous reduction of all pollutants should be encouraged.*

C. SHIFTING GENERATION

Shifting of electricity generation to outlying plants during an incident of serious adverse meteorological conditions appears practical under some circumstances, but only to a limited extent. Chicago, with the Argonne National Laboratory assisting, is developing a future power distribution model for the city. This is a NAPCA-supported activity. It appears possible to shift

about 25 percent of the generation within the Chicago service area, without calling on outside service areas. For an eastern seaboard situation this may also be practical, but the panel has no basis for predicting the extent to which this would alleviate a particular situation. Most utilities in a metropolitan region would be able to do a substantial amount of good within their regions. Shifting generation may aid some peak pollution crises in other metropolitan areas. However, there must be idle capacity available beyond the influence of the poor atmospheric conditions if this is to be effective.

A long-term plan for such an operating procedure over the years would require additional investment to provide stronger transmission ties to permit shifting substantial amounts of power, as well as very substantial investment in system reserve generating capacity. Such a mode of operation would incur increased operating costs, because the system would not be operating at its economic optimum.

D. A NATIONAL ELECTRIC TRANSMISSION GRID

A survey of energy reserves in the United States and the status of nuclear reactor development have led to the suggestion that systematic plans be made for the development and utilization of western coal deposits and to a recommendation for a national electric power transmission grid.[12] Since the potential power generation centers based on these fuel sources are distant from the power demand areas, the cost of fuel transportation and energy transmission becomes an important factor in the feasibility of using western coal and oil shale reserves. The argument becomes even stronger when viewed in terms of the many siting problems of large generating stations whether they are coal-, oil-, gas-, or nuclear-fueled.

A national energy transmission grid might consist of a number of highly efficient, primary lines connecting major generating and consuming areas of the country. Secondary tie lines would then branch out from the primary lines much like the existing power-pool

transmission lines. Preliminary economic analysis[12] indicates feasibility and additional potential benefits in communication and by-products manufacture. Planning, coordination, and implementation of such a venture must be accomplished at the national level. It is appropriate to note here that transmission lines pose significant environmental problems of their own, which may be solved eventually by placing them underground.

The design, construction, and utilization of a very low resistance (super-conductive) national electric energy transmission system would have many advantages, including: (1) implementation of an effective national fuels and energy policy; (2) management of environmental factors related to energy generation, transmission, and utilization; and, (3) improvement of security and reliability of energy sources, generation, transmission, and utilization.

Long-term, broad-scale planning of this magnitude is important in meeting the problems of environmental quality, energy requirements, economic development, and national security.

E. LONG-TERM ENVIRONMENTAL CONSIDERATIONS

The buildup of CO_2 in the atmosphere has not been an important consideration in most air quality improvement planning, and the *ad hoc* panel was not charged with reporting on the long-term global temperature and ecological effects of increasing concentrations of long-lived air pollutants. But is appropriate to remark that CO_2 and submicron-size particulates are the only contaminants resulting from combustion and reduction processes that may be of importance to global ecology. A portion of the submicron particles are sulfate aerosols formed by the reaction of SO_2 in the atmosphere.

Combustion of fossil fuels, a major source of SO_2, is also the source of perhaps 50 percent of the atmospheric buildup of CO_2. Because of this relationship to energy requirements and fuels availability, the panel believes that a discussion of SO_2 pollution must also include recognition of the possible long-term

effects of increasing levels of CO_2.[10] By the year 2000, it is estimated that there will be a 25 percent increase in CO_2 in the atmosphere, compared to the amount present during the nineteenth century. It is further estimated that this increase may affect the earth's radiation balance causing a corresponding increase in the average temperature near the earth's surface.

However, it has been pointed out[6] that there is also a possible worldwide change in the amount of atmospheric fine particles. In addition to particles rising from the earth's surface, significant quantities may be deposited directly in the stratosphere by supersonic transports when they come into extensive use. An increase in fine particulate materials, some of which are SO_2 decay products, may have the effect of increasing the reflectivity of the earth's atmosphere and reducing the amount of radiation received from the sun.[11] This effect would be the opposite of that caused by an increase in CO_2. It is suggested that the large-scale cooling trend observed in the Northern Hemisphere since about 1955 is due to the disturbance of the radiation balance by fine particles and that this effect has already reversed any warming trend due to CO_2.

Whichever may be the case, *it is clear that considerable uncertainty exists as to the effect of long-lived pollutants on the environment.*

Nuclear power presents several potential air pollution problems.[3] Solid waste from radioactive materials in spent fuel rods appears to be a relatively small air pollution problem but is a significant solid waste disposal problem. There are important questions regarding the effects of small amounts of tritium (half-life of 12.26 years) present in the cooling water. The tritium may enter biological systems and produce radiation effects and damage during its decay. Finally, krypton-85 (half-life of 10.4 years) released at the reactor and the fuel reprocessing plant might accumulate in the atmosphere over an extended period, much like carbon dioxide. At some time it may become necessary to collect the tritium and krypton for storage rather than release to the environment.

IV

ENERGY RESEARCH

The National Air Pollution Control Administration has been designated the Federal "lead agency" to provide objectivity, coordination, emphasis, and support to the national efforts to restore and control the quality of our air environment, including:

1. Accumulation, interpretation, and dissemination of all pertinent information

2. Coordination of short-, medium-, and long-range planning of research, development, and demonstration activities of Federal groups such as the Atomic Energy Commission, Tennessee Valley Authority, Federal Power Commission, Bureau of Mines, Office of Coal Research; and state, regional, and local agencies as they relate to air quality factors resulting from extraction, processing, transportation, and utilization of energy resources

3. Planning, initiation, coordination, and funding of research, development, and demonstration of broadly acceptable systems, subsystems, and components as required to reduce air pollution to acceptable levels

Accomplishment of these objectives will require a high level of planning and coordination between the several governmental, research, legislative, industrial, and civic groups involved to: (1) evaluate feasible and acceptable alternative courses of action, (2) determine present and future consequences of specific action or inaction, (3) evaluate the impact of changes on one or another element of the system, (4) determine priorities and funding levels, and (5) select the most broadly acceptable courses of action.

The complexities of the national energy-generation and energy-utilization system will increase with

time. However, careful planning and coordination of national and regional efforts, not only for SO_2 control, but also for control of other air, water, thermal, visual, and solid waste pollutants, will minimize future problems related to environmental degradation associated with plant siting, transmission systems, fuels utilization, engineering feasibility, economics, and public acceptability. Planning and coordination activities of this magnitude present a major national challenge to keep pace with the 6 percent projected annual increase in electricity requirements and still maintain an acceptable environment.

Each year the Federal Government supports research and development to improve methods for producing, converting, and transmitting the primary energy sources--petroleum, gas, coal, oil shale, uranium, and water power. Table 2[1] provides an accounting, by primary energy source, of Federal research and development funds currently being devoted to the task of assuring an abundant supply of energy at reasonable costs to meet the nation's future needs, with minimum impairment of the quality of the environment.

In addition, industry spends hundreds of millions of dollars annually for research and development, with the petroleum industry accounting for a substantial portion of the private expenditures in the energy field. Substantial amounts are spent by utilities and manufacturers on electric power generation and transmission equipment and nuclear fission as part of their facilities development. However, industrial research and development expenditures on coal, oil shale, hydroelectric power, and controlled fusion are but a fraction of the Federal program in this area.

The important bases for viewing research and development expenditures in Table 2 are the energy generation patterns in 1980 and 1990 (Figure 1), and these, in turn, are influenced by the success of present research and development. The relative stage of development of each form of energy conversion must also be considered, since the costs of developing a new technology, such as nuclear fission or fusion, are

greater than those for improving existing systems involving other forms of energy.

The energy conversion efficiency of fossil-fueled power plants appears to have stabilized after gradually increasing over the years. New fossil-fueled steam power plants currently have efficiencies of about 40 percent in converting the fuel combustion energy into electrical energy. Present commercial nuclear power plants range from about 30 to 35 percent in conversion efficiency, and breeder reactors are expected to reach about 40 percent efficiency. Combined cycle systems, are, in principle, more efficient energy conversion facilities. For magnetohydrodynamic generation using fossil fuels, with a steam plant to utilize the energy contained in the hot gases leaving the magnetohydrodynamic unit, the combined efficiency is projected to be on the order of 50 to 60 percent.[12] The high temperature required will cause increased nitrogen oxides formation. Improved efficiency reduces the amount of fuel required and the amount of heat rejected to the environment to meet a given demand. For sulfur-bearing fuels, the SO_2 emission would be correspondingly reduced.

V

FACTORS OF FUELS UTILIZATION

Fuel use patterns are dependent upon supply (availability) and on certain technical developments in fuel production, energy conversion, and energy transmission. Projections indicate maximum production of natural gas in the United States within 10 years and of petroleum products within 30 years. [8]

The Atomic Energy Commission estimates that in the year 2000 nuclear energy will supply about 44 percent of the national electricity generating capacity, coal about 41 percent, and gas, oil, and hydroelectric power about 15 percent. Present fuel sources for electricity generation are: nuclear, 1 percent; coal, 65 percent; and gas, oil, and hydroelectric, 34 percent. Serious delays in construction schedules of several nuclear power plants have occurred during the past year, and the cost estimates per installed kW have risen from about $130 in 1967 to about $200 in 1970.[13] Cost for fossil-fueled plants were about $110 to $130 per kW in 1967, and are $120 to $160 per kW in 1970. These costs include particulate-control devices, but do not include equipment for SO_2 or NO_x control. *Recently, a number of orders for fossil-fueled plants, with shorter lead time and lower capital costs, have been placed by utilities to meet power requirements that nuclear plants might have met under earlier construction schedules.*

These factors indicate a greatly expanded use of coal as an energy source during the next 30 to 40 years (Figure 1). The United States has an assured reserve of coal and oil shale to meet its energy needs for hundreds of years to come. Some changes in the schedule are dependent upon the development of:

1. Early resolutions to siting, environment, and economic problems related to present and future power plant development

2. Processes for more effective coal desulfurization

3. Processes for conversion of coal to "clean" gaseous or liquid fuels

4. The fast breeder nuclear reactor, which will reduce nuclear fission fuels costs and extend nuclear fuel resources

5. Various combined cycles such as magneto-hydrodynamic generators, which are potentially more efficient than steam turbine generators

6. Industrially efficient processes for the extraction of oil and gas products from oil shale

7. The controlled nuclear fusion reactor, which would make large amounts of energy available

Difficulties with equipment delivery and plant siting have already seriously delayed the construction of generating capacity in parts of the United States. The Federal Power Commission states that 39 of 181 major systems have reserves of less than 10 percent peak load. There is a real possibility of power shortages and "brown-outs" in some power pool areas during peak-load periods of the next several years.

At many inland sites, river water and ground water are no longer available in sufficient quantity to be used for once-through cooling; hence, evaporative cooling towers have come into fairly common use. At several locations, in the eastern as well as far western parts of the country, even the demand for make-up water for cooling towers (about 2 to 3 percent of the once-through rate) exceeds the amounts available from rivers and existing wells without endangering the river flow or the water table. In England, this situation has resulted in installation of closed-cycle cooling systems that exchange heat to the air through finned

heat exchangers.[2] Costs, of course, increase substantially with the transition from once-through to closed-cycle cooling systems.

There is also some thought that man's future needs may be better served if substantial reserves of coal, petroleum, natural gas, and oil shale are set aside for the rapidly growing requirement for chemical industry feed stocks. Such a reserve will, of course, depend largely on the beneficial application of developing nuclear technology. Thus, the critical need for development and application of technology to control pollution resulting from fossil fuel (particularly coal) combustion may well occur between now and 1985 or 1990.

In view of these consideration, it is evident that SO_2 problems that are generally restricted to coal use (and in a smaller way to ore smelting and petroleum use) will grow until SO_2 control processes or other energy sources are developed. Thus, *the SO_2 abatement problem fits into the larger problems of fuel policy and management.*

VI

TIME PHASES OF TECHNICAL DEVELOPMENTS

Successful development and application of several control processes and the breeder reactor are crucial in the abatement of sulfur oxide emission to the atmosphere. As shown in Figure 2, assuming the breeder reactor comes into wide application after the year 2000, coal consumption and sulfur emission would peak and decrease rapidly even without emission control.

Research on fast breeder nuclear reactors is proceeding rapidly in several countries. The British 60 MW pilot breeder reactor at Dounreay, Scotland, went critical in 1959 and has operated continuously except for a 1-year shutdown during 1968-69 to repair a leak. The United States 150 MW "Fermi" breeder reactor in Monroe, Michigan, first went critical in 1963. It was shut down in October 1966 due to a subassembly meltdown and is scheduled to start up again in 1970. The Atomic Energy Commission is now selecting a site for a 500 MW demonstration breeder power reactor to start in 1976. Projections call for the first commercial breeder reactors of the 1,000 MW size to start up about 1985 in the United States.

Fuel substitution has already begun to be practiced but is restricted by the limited availability of low-sulfur oil, coal, and natural gas. More intensive cleaning of coal to remove pyrite may make a contribution to sulfur-emission control comparable to fuel substitution as it comes into wider use in the next few years. Although limestone processes for the removal of SO_2 from stack gases--which do not produce a marketable product--should be commercially proven in the next 1 to 3 years, broad application of these processes will require several more years. Several product-producing processes for SO_2 removal should be commercially available in the mid-1970's or early 1980's and should find wide application in the new coal-fired plants. With adequate funding and experimental success, new combustion technology should be available in 5 to 8 years.

As with the breeder reactor, there is no assurance that the control processes will be developed as predicted. *The time estimates are realistic only if there is a positive commitment on an urgent basis by government agencies, utilities, fuel suppliers, and equipment manufacturers to support the orderly development and timely application of these processes.*

The sequence of technical developments must be coordinated with the plans for compliance with air pollution control regulations and the availability and use patterns of various fuels. As the national air quality control regions implement their criteria and emission control schemes to improve the quality of the air, there will be a growing need for the different kinds of technology and a shifting in types of fuel used.

For example, in the Washington, D.C., area, plans are being developed for the National Capital Interstate Air Quality Control Region.[7] In addition to a reduction in suspended particulate matter, it is proposed that all fuels burned in the region must contain 1 percent or less sulfur. It is also proposed that, after July 1, 1971, distillate fuel oils (ASTM No. 1 and No. 2) should contain 0.3 percent or less sulfur. Fuels containing in excess of 1 percent sulfur could be burned, provided control equipment to desulfurize stack gases had been installed or other methods were used that would produce results equivalent to the burning of fuel containing 1 percent or less sulfur.

All fuel-burning installations constructed and all fuel-burning installations altered or modified for use of a different fuel having a maximum heat input of less than 250 million Btu's per hour would be required to burn gaseous fuels, provided that distillate fuel oils could be used for not more than 30 days in any calendar year. However, liquid and solid fuels could be burned, provided it were demonstrated that sulfur oxides, particulate matter, and nitrogen oxides emissions would be equal to or less than would result from burning gaseous fuels to accomplish the same heating objective

At this time, the complete substitution of gas, or low-sulfur oil, for coal in Washington, D.C., appears to be the only possible way, short of establishing an all-electric city, to achieve the long-term goals that are being considered.[7] Other proposed actions include control of open burning and tighter limits on emissions of particulates and sulfur oxides from incinerators and industrial operations. These suggestions, of course, are not to be taken as courses of action recommended by the panel.

To meet such goals in other cities, it would be necessary for industrial plants to install more efficient particulate control on all stacks, and SO_2 scrubbers on many processes. Heating systems would have to convert to gas, low-sulfur oil, or electricity, depending upon fuel availability. Existing power plants would need to convert to oil or gas or add stack removal of SO_2, and new plants would use nuclear energy, gas, or perhaps something like fluidized bed combustion of coal.

Such shifting would require the expansion of gas and oil supply systems. Since natural gas reserves are limited, both coal gasification and importing of liquefied natural gas would probably be necessary to meet the increased demand.

There is a possibility that a number of the newly created air quality control regions will adopt plans such as those described above in the next few years. *Care must be exercised at the local, regional, and national levels to assure that realistic criteria and plans are adopted which can be implemented in concert with the development of technology and the systematic use of our energy resources.*

There is a real danger that the public may be led to expect environmental improvements at a rate that cannot be realized. This is not to say that high goals should not be established, but rather that realistic and coordinated implementation plans must be adopted.

VII

SUPPORT OF TECHNOLOGICAL PROGRESS

The objective of support of technological progress in SO_2 emissions control is to advance the state of the art with all deliberate urgency consistent with prudent engineering and economic judgment and national needs.

The Federal effort to achieve the necessary sulfur oxide control should be in partnership with the electric-power industry, equipment manufacturers, and the fuels industry. Eventually, sulfur oxide control may create a market that will offer some industrial incentives. Meanwhile, implementation of SO_2 control plans is a major national problem that will require large expenditures by the utilities and large costs to consumers, unless technology is developed that will minimize these costs.

In seeking suggestions for enlisting the private sector in support and augmentation of the Federal effort, the panel found that in recent years many companies have spent up to several million dollars developing their processes to the pilot scale and beyond (Chapter VIII). Other companies, some with interesting technological approaches, do not have adequate funds even for bench-scale work. Within industry, the competition for research and development money is such that the expenditure of $5 million to $10 million of a company's funds on commercial demonstration of one process may be a poor research and development risk when compared with alternative projects of corporate interest.

A. COAL INDUSTRY

The coal industry is not process-research oriented and its air-pollution research and development has been fragmented. To date, the industry's effort has been limited to a few modest projects that have been conducted by several major companies and with sponsorship by Bituminous Coal Research, Incorporated

(BCR). Work within individual companies has been largely concentrated on methods for removing ash and sulfur from coal. The work at BCR, which is supported broadly by the industry, has been devoted to stack gas cleaning processes and coal cleaning, with the predominant emphasis on the latter.

B. EQUIPMENT MANUFACTURERS

The panel learned that the equipment suppliers see no immediate profit potential in the research and development of new SO_2 control equipment under present accounting and taxing policies. What the equipment manufacturers do develop can seldom be protected from use by competition, because very little of such equipment is proprietary or subject to patents that cannot be circumvented. A manufacturer may invest his money and develop a sulfur control process using equipment that he manufactures, only to find that similar equipment is available from many manufacturers, and the utility applying the process may seek competitive bids. Consequently, patents on equipment of this type are regarded as relatively worthless. Patents on a process may be valuable, but the overall situation is such that little acceleration of the research effort can be expected to follow automatically in the private sector, even when sulfur control regulations become more stringent.

Despite these considerations, equipment manufacturers are developing new equipment for air pollution control applications and have participated in a number of joint pilot, demonstration, and feasibility studies.

C. UTILITY COMPANIES

As regulated monopolies, electrical utility companies are subject to the control of various governmental bodies, Federal, state, and local. Consequently, funds spent by utilities for development and application of pollution control processes may not be readily included in their capital structure, which is the basis for establishing consumer rates.

The utility companies, however, are supporting sulfur oxide emission control studies individually and jointly. Over 25 utilities are participating in research, development, and demonstration work on several promising processes (Chapter VIII). The panel agreed on the following points with respect to support by the utility companies of research, development, and demonstration (R,D,&D).

1. Funds spent for development and application of pollution control processes may not have the potential of self-liquidation under present rate-making policies.

2. Many utilities located in urban areas are making determined efforts to secure reliable sources of low-sulfur fuels and installing equipment for multiple fuels capability.

3. The costs of developing and applying control processes will be high; the utilities are neither equipped nor staffed to do the kind of process development and demonstration that is needed. Because of the expense and time involved, it is probably not realistic to expect individual companies to carry out impressive internal R,D,&D programs.

4. The technological risk of applying processes that are inadequately demonstrated is too great to force acceptance and installation of these processes. The most likely effect of legislative pressure will be to force the use of the limited supplies of available low-sulfur fuels. Therefore, until reliable processes are adequately demonstrated, the effectiveness of legislative pressures will be limited.

5. It might be possible for utilities to do more cooperative R,D,&D. Regulatory and taxing agencies might consider adjusting their policies to encourage such activity.

D. FEDERAL GOVERNMENT

Even if additional cooperative funding by the coal industry, equipment manufacturers, utility companies, and process developers can be arranged, government support will be needed for many years to encourage development, demonstration, and application of sulfur oxide control technology. *Unless the necessary technology becomes available, the country may have to choose between clean air and electricity.*

The crux of the problem is its urgency with respect to lead time and degree of applicability of any single process. The schedule for abatement of the emission of sulfur oxides reduces the lead time to a very short period. In order to demonstrate a variety of processes which might be applicable to specific conditions, *the reduction of lead time and the diversity of processes required demand an intensive and concerted effort substantially greater than normal industrial process development.*

Although no control process has yet reached the stage of demonstrated full-scale application in a power plant, several methods that may be suited to particular sets of conditions are under development and should be brought to a stage of industrial efficiency with all deliberate speed. *This can be accomplished most expeditiously by adequate funding of NAPCA in its role as Federal "lead agency" to assure significant progress in an acceptable period of time.*

There are three stages of process development at which Federal support and encouragement are justified:

The first stage is in unrestricted broad-ranging investigations. Such pioneering investigations should normally be restricted to bench-scale work and are worth supporting on a continuing basis.

The second stage involves pilot-plant trials of new processes that appear to be promising.

The third stage comes after pilot-plant trials have been concluded, and when the most promising processes are considered ready for demonstration on a scale that would provide engineering and economic data that could be projected with confidence to large operating units. Such large-scale demonstrations are necessary and will be quite expensive, running into several million dollars for each process selected. This is a critical point in the application of new technology. National needs will be most effectively accomplished by a full partnership (financial and technical) between government agencies, utilities, equipment manufacturers, process developers, and fuel suppliers.

In addition to support of research and development, governmental assistance may be provided through changes in tax and patent policies and provisions for Federal funding of "risk capital." The proposed Tax Reform Act allows accelerated amortization of pollution control equipment. The prospect of profitable patents is an incentive for further research by industry. Several government agencies are reviewing patent policy at this time to determine what changes might be made to encourage research, development, and application of processes designed for pollution control. The Patent Office has recently announced its intention to accelerate the handling of applications dealing with pollution control inventions.

In addition, the Subcommittee on Air and Water Pollution of the Senate Committee on Public Works has heard testimony in recent hearings on S.2005--The Resource Recovery Act of 1969, S.3469--The Wastes Reclamation and Recycling Act of 1970, and the Amendment to S.2005, cited as the National Materials Policy Act of 1969. Federal provision for "risk capital" was one of a variety of subjects discussed. Other approaches of financing of research, development, demonstration, and application of processes and facilities designed to control various types of pollution are being considered at the Federal executive and legislative level.

VIII

PRESENT STATUS OF RESEARCH AND TECHNOLOGY

A. AVAILABILITY OF TECHNOLOGY

Although the panel is optimistic that acceptable sulfur oxides control technology will be developed, it concludes that this technology is not yet commercially proven. Moreover, a rapid pace must be maintained in pursuit of the technical objectives, if only to prevent conditions from getting worse. Even when the expected technology becomes available, it will be too late to prevent a significant rise in total sulfur emissions during the next several years.

Five general approaches might be made to sulfur oxides control problems:

1. Undertake a crash program to build nuclear power plants
2. Remove sulfur from fuels before they are burned
3. Remove sulfur from fuels during the combustion process
4. Remove the SO_2 from the combustion gases before emission to the atmosphere
5. Employ very high stacks and remote siting so that the gases are dispersed and diluted to an acceptable level

The first approach is impractical because of the prohibitive expense and inability to meet even present construction commitments. Some combination of the second, third, and fourth approaches offers the best promise in the United States. However, the processes to accomplish sulfur removal from coals before and during combustion, and from combustion gases, are not adequately developed, and are not immediately acceptable for wide application. Tall stacks and

remote siting, the fifth approach, are being promoted in England and to some extent in the United States.

Sulfur is readily removed from distillate oils, and the technology is well established. Residual fuel oils are more difficult to treat, because they contain metals that deposit on the solid catalysts employed. The petroleum industry has invested heavily in the development of ways to desulfurize fuel oil, and there is no doubt that some of these methods will work. The plants required are costly, and the added refining step of reducing the residual fuel oil from 2.6 to less than 1.0 percent sulfur will probably increase the price to the power station by 50 to 80 cents per barrel. This represents an increase in fuel cost of 20 to 35 percent. Fifty cents per barrel of oil is equivalent to an increase of about 0.7 mills per kWh in power costs.

Sulfur in coal is present principally as the mineral pyrite and in complex organic compounds; in these two forms, it exists in widely varying ratios. With some coals, pyrite can be largely removed by grinding and washing, but, on the average, only about half can be removed, using existing coal cleaning technology. It appears that organic sulfur may be removed only by hydrogenation, liquefication and gasification processes.

Preliminary results of NAPCA's survey of naturally occurring low-sulfur coals and washability characterization tests of coals available for uses other than for metallurgical coke production suggest that of the steam-coal production: 8 percent has 1 percent or less sulfur as mined and could be cleaned further; 11 percent is coal with over 1 percent sulfur that is easily cleaned; and 6 percent is coal with over 1 percent sulfur that is cleanable at a higher cost. Thus, perhaps, 25 percent of the steam-coal production is capable of being cleaned to produce coal with a maximum of 1 percent sulfur.

NAPCA further estimates that refinement and broader application of coal cleaning technology might

result in an average reduction in sulfur content of the remaining 75 percent of steam coals by as much as 40 percent.

Coal washing costs may range from 25 to 75 cents per ton of cleaned product.

Where fuel desulfurization is practical, it offers the most obvious and direct method to reduce SO_2 pollution from combustion. Several processes are under development for the production of liquid and gaseous fuels from coal, and liquid fuels from oil shale, and will perhaps be demonstrated to be industrially feasible within a decade. Meanwhile, most of the needed coal cannot be desulfurized to a maximum of 1 percent sulfur by use of presently available technology.

At least two processes offer hope for removal of sulfur during combustion: (1) "fluidized bed" combustion, and (2) "molten iron bath" combustion. Optimistically, the perfection of these techniques as commerical processes is 3 to 8 years away, and there is some question that either can be retrofitted into existing plants. If successful processes can be developed, their major application will be in plants that are engineered and constructed after the processes are determined to be applicable on a commercial scale.

Many ways of removing SO_2 from stack gases are being actively investigated--all involving some means of contacting the gas with a substance that removes SO_2. At least 25 such processes are under development in this country by industry and by NAPCA (Appendix C), and others are under development in Japan and Europe (Appendix D). Most are bench-scale laboratory projects, but several have reached the pilot-plant stage (10- to 25-MW equivalent gas streams). Only the limestone-wet scrubbing process has been installed in sizable operating power plants. Several of these processes will probably be technological successes, but the efficiencies are not yet well established for even the most advanced. Projected costs range up to 1 mill per kWh and, in some cases, higher, depending upon method of financing.

Although SO_2 emissions are not decreased by remote siting and tall stacks, these measures help reduce ground-level SO_2 concentrations in urban areas. As previously discussed, even with application of sulfur removal processes, tall stacks will continue to be necessary for large power stations to disperse and dilute all remaining emissions, including carbon dioxide, nitrogen oxide, and water vapor.

It should also be noted that the possiblity of establishing one national air quality control region and broader international and even global cooperation in environmental quality management may require national emission standards.

The future of sulfur control is not hard to predict in general terms. The country is committed to reducing air pollution, and increasingly stringent standards regarding sulfur concentrations in the ambient air are being established. Users of high-sulfur fuels will attempt to switch to natural gas, desulfurized fuel oils, or low-sulfur coals, all of which are in limited supply. These will command a premium price over present fuels. Where practical, the coal industry will find more intensive treatment of steam coals profitable. Where possible, new mines in known low-sulfur coal deposits will also be opened. It normally takes about 3 years to bring a new mine into full production.

Because these developments will not meet the total requirements of low-sulfur fuels necessary to control the continuing increase in sulfur emissions, many presently operating utilities will have no near-term alternative except to install facilities to remove sulfur from stack gases. Probably, the simpler methods, which produce "throw-away" by-products, will be the first to be adopted by many existing plants. The more complicated processes, which produce sulfuric acid, SO_2, or elemental sulfur, may be demonstrated in 3 to 10 years.

By perhaps 1980 or 1985, sulfur emissions stemming from smelters and the combustion of fossil fuels will be under fairly good control, although total sulfur emissions will have risen substantially over those at the present time. By 1975 to 1985, there may be ways to burn coal, such as by fluidized-bed combustion in the presence of lime, to fix the sulfur so it is not carried by the stack gases.

B. THE NEED FOR COMMERCIAL DEMONSTRATION

It is important to note that industrially proven technology for the control of sulfur oxides resulting from fossil fuel combustion does not now exist. Only one of the several processes under development has been installed in 100-MW or larger boilers, and it has operated only intermittently.

Data on processing variables accumulated during each stage of process development are evaluated to determine the feasibility of scale-up to the next stage. If feasibility at the bench and pilot scale has been established, prototype industrial scale operation for a minimum of 1 year is necessary to secure sufficient knowledge of the process to establish control parameters, operating reliability and efficiency, maintenance requirements, adequacy of materials and engineering, and ability of the process to meet air quality objectives.

Consequently, *there is an urgent need for commercial demonstration of the more promising processes, to make reliable engineering and economic data available to engineers who are designing full-scale facilities to meet specific local and regional conditions.* The panel's definition of proven industrial-scale acceptability is satisfactory operation on a 100-MW or larger unit for more than 1 year. Also, technical and economic data developed must be adequate for confident projection to full commercial scale. Pilot scale refers to investigation using flue gas in the capacity range of 10 to 25 MW. Smaller sizes and studies using synthetic gas mixtures are considered to be bench scale.

Estimates of industrial-scale feasibili and adequacy of a process based on paper studies or bench-scale projections are, by their very nature, too speculative to be reliable in making large-scale economic or engineering choices between alternative processes. Such estimates do, however, provide a basis for decisions related to the next level of scale-up. The estimates of installed cost per kilowatt range from $4 to $40 for the processes under development. If the figure were $10, the cost to install control equipment in existing coal-fired power plants would be about $2.2 billion. Total operating costs may be of the order of 0.5 mill per kWh. These are not reliable estimates of the ultimate cost to the consumer of electricity, but they do serve to indicate the magnitude of the problem of SO_2 control.

Even though the technical feasibility of a process were indicated on a pilot-plant scale, industry would be understandably hesitant to fund a large installation prior to full-scale evaluation. For a utility, the risks of failure to meet air quality objectives--as well as operational objectives--are great. For the nation, the possibility of delaying effective SO_2 control by installing equipment that does not do an adequate job is also great. When national objectives call for accelerated construction of high risk, large investment, and the use of unproven processes, it is proper for the government to share in the risks by participation in those portions of the project that are first-of-a-kind engineering demonstration units.

The development of several of the processes for removal of sulfur from stack gases is well advanced. Pilot plants of up to 25 MW have demonstrated to varying degrees the technical feasibility of at least three of these developments. The diversity of the schemes being developed is gratifying, because quite different technical solutions will be required to meet the wide variety of situations in which sulfur control is necessary.

The panel believes that it would be appropriate and very much in the national interest for NAPCA,

under Section 104(a)(4) of the Clear Air Act of 1967, to provide support of several million dollars, in partnership with industry, to expedite the first commercial demonstration installation of each of several promising processes for SO_2 control.

C. BACK-FITTING EXISTING PLANTS

The dry- and wet-limestone processes could probably be used by many existing plants. These are by no means the final solution, and other processes involving by-product recovery should be developed.

Many stations have limited areas in which they can dispose of the ash, and would have to haul it away. For some older plants in crowded areas, very little space is available; forcing them to utilize large quantities of limestone could result in their conversion from coal to a low-sulfur oil. Sometimes, simply upgrading the electrostatic precipitator for the dry-limestone process would cost more than to convert from coal to an oil-fired unit utilizing low-sulfur oil. In addition, for a given precipitator efficiency, a threefold increase in fly ash will nearly triple the particulate emission.

The existing smaller power plants have the other alternatives of obtaining low-sulfur coal, oil, or gas, if supplies of these fuels are available. These alternatives are also available to large plants, but the panel believes that, *from a national point of view, the most logical use for the low-sulfur coal is in commercial and industrial plants, small power plants, space heating, and for production of metallurgical coke.*

The forward-looking utilities are providing space in new plants, in anticipation of the necessity of installing corrective measures for flue gas treatment. They are allocating space or buying enough land to enable them to fit in the technology more easily when it is available. One restriction of this policy is that it provides only for the type of process that would take gases at the usual discharge temperature

of 300°F. It would not easily permit installation of a process that requires use of the high-temperature part of the boiler. The plan is to minimize the back-fitting cost on a 300°F process. Those processes that are designed to operate at 600°F to 900°F will require about 3 years' lead time, and the back-fitting will cost much more than if control technology were available and could be incorporated in the initial design.

D. CENTRAL RECOVERY FACILITY

Utilities may find product-producing processes more attractive if a central chemical processing plant can be employed to collect and regenerate the absorbents or adsorbents from several installations. This appears to be an interesting possibility in connection with several of the schemes that produce salable chemicals.

The suggestion has been made that the chemical industry be brought into partnership with the electric power industry. It is feasible to have a separate chemical operation that would serve a number of utilities. The attractiveness of this scheme depends on the distance and the transportation involved and the method of financing. It would probably have to be a facility financed by the electric power industry and operated by the chemical industry under a contractual arrangement. It is possible that the utility could pay enough for the return of the absorbing medium to make it attractive for the chemical company.

A central facility is attractive for several reasons:

1. The utilities evidently prefer not to get into the chemical business.

2. The recovery operation in many of these processes requires facilities and space comparable to the boiler plant.

3. The economy of scale for a central unit would be better than that of a single

utility plant, in which the installation of a chemical plant of uneconomic size would not be feasible.

4. The central processing facility could operate at a higher and more uniform rate than one located at, and dependent on, a single power station operating on a varying load factor.

It has been suggested that the ultimate control facility might be a combination major power plant, petrochemical, and sulfur-chemical complex. Coal chemicals are presently produced in quantity during coke manufacture by the steel industry. These organic chemicals are used as feed stocks for petrochemical processes in competition with petroleum refinery products. A similar activity may evolve from the utility companies as they strive to reduce pollutant emissions from coal and other fossil fuels used in power generation.

E. RESEARCH PLANNING

From a national point of view, the research strategy should be to have several processes in commercial operation at the earliest possible date. Primary emphasis should be placed on achieving industrial feasibility for the processes that can be readily incorporated into existing power plants, even though some of them may produce only nonsalable or throw-away by-products. Successful development of these processes would do most to alleviate air pollution in the shortest possible time.

Besides development of throw-away processes, development of product-producing processes must be continued. For the new installation, improved processes, including steps to recover some value from the sulfur, will be necessary to keep costs for future control within reasonable limits. Installation of many of these processes in existing plants would require major changes. Consequently, they are unlikely to be found broadly applicable to plants now in existence. Compliance with the standards that may be promulgated

within the next year or two will be extremely difficult at best, and may be impossible, even with the development and installation of the throw-away processes that appear to be nearly ready for installation.

The limestone injection processes expected to be available in 1 to 3 years will probably not be adequate for the long-term requirements, and NAPCA should continue to support the development of sulfur-recovery processes.

Coal cleaning should be studied further, at least on a small scale, until its sulfur reduction potential is clearly defined. Imaginative new methods for removal of both pyritic and organic sulfur from coal should be encouraged.

The panel places special emphasis on the following:

1. Complete development of the limestone process should be given high priority because it seems applicable to existing boilers. At the same time, NAPCA should support long-range research on processes that industry will be slow to develop. Fluidized bed combustion, which has potentially attractive antipollution features, is such a process.

2. Coal cleaning processes should be refined to their maximum potential. Promising new concepts in coal desulfurization should be supported.

3. Processes for desulfurization of fuel oil are being developed by several petroleum companies. It is believed that NAPCA cannot, nor should it, contribute significantly to these developments.

4. Probably, much of the NO_x will have to be removed from stack gases or combustion temperatures controlled to reduce its

generation. Only two of the SO_2 processes under development appear to be potentially effective in removing oxides of nitrogen. *Research on ways to combine SO_2, NO_x and particulate abatement should be supported.*

5. NAPCA should employ a *process engineering and construction firm* to project costs on a *common basis* for all of the promising processes at various stages in their development. This not only would provide more reliable estimates of the ultimate cost of sulfur control, but also would provide NAPCA with a valuable guide in contract allocation and scale-up decisions.

6. Recovery of sulfur in the elemental form is desirable for storing and handling. Though acid-producing processes will find application in special marketing situations, acid sales will generally be limited by shipping costs.

7. Most of the processes using regenerable absorbents or adsorbents produce SO_2. The conversion of SO_2 to elemental sulfur is not a common industrial process, and it is important that the technology of this conversion be thoroughly studied.

8. The following general considerations should be kept in mind in choosing processes for development:

   a. Insertion of equipment ahead of the air preheater is a radical change in power plant design that may find slow acceptance in the power industry.

   b. Parallel absorber-regenerators, which require shifting the gas flow from one vessel to another, will necessitate large investments in

dampers or other flow control apparatus.

c. Solid absorbents are subject to attrition and to chemical deterioration.

d. Finely divided solid adsorbents are difficult to recover completely from the gas stream.

e. Processes that involve flow of the stack gas through all the equipment, both for absorption and regeneration (or other type of product recovery), have relatively high capital cost.

f. High absorbent loading and good mass transfer and sorption kinetics are important in keeping equipment size at a minimum.

g. Gas reheating, while expensive, may be needed to take care of the loss of buoyancy of stack gas in some treatment processes.

h. Impurities will accumulate and cause trouble in absorbent-recycle processes.

i. The disposition of sulfate formed is a major problem in any absorption process.

j. Processes that lead to fertilizer products may be desirable under some circumstances, because much of the recovered sulfur can be used by the fertilizer industry.

F. PROCESS DEVELOPMENT

1. General Considerations of Individual Processes

Brief commentaries on each class of the processes reviewed by the panel are presented here with special emphasis on the general process considerations. In each of the descriptions, the current level of knowledge about the process is reflected in the state of process development (bench, pilot, or demonstration level).

Generally speaking, bench-scale work may proceed for several years, depending upon what is already known about each of the individual steps of the process. Pilot-plant design and construction may take from a few months to more than a year following completion of bench-level work. Normally, the pilot plant would be operated for about 1 year. Scale-up, together with design and construction of a demonstration plant, following successful pilot-plant studies, takes from 1 to 2 years. Demonstration work will take 1 to 3 years to provide adequate information about the process. Thus, a process for which bench-scale studies have been completed is generally at least 4 1/2 years away from industrial feasibility, assuming success in subsequent studies. The schematic in Figure 3 summarizes the time scale for process development.

The panel was impressed by the readiness with which full information concerning the several proprietary processes was disclosed and has no reason to suspect that there is a major domestic effort on SO_2 control that has not been reported because of proprietary reasons.

A wide variety of processes are being considered in the United States (Appendix C) and in foreign countries (Appendix D). A number of these are reviewed here--particularly those that are receiving the most attention in the United States. In most cases, the developers are seeking funds from industry or Federal agencies, or some combination of the two to supplement corporate funds in expediting

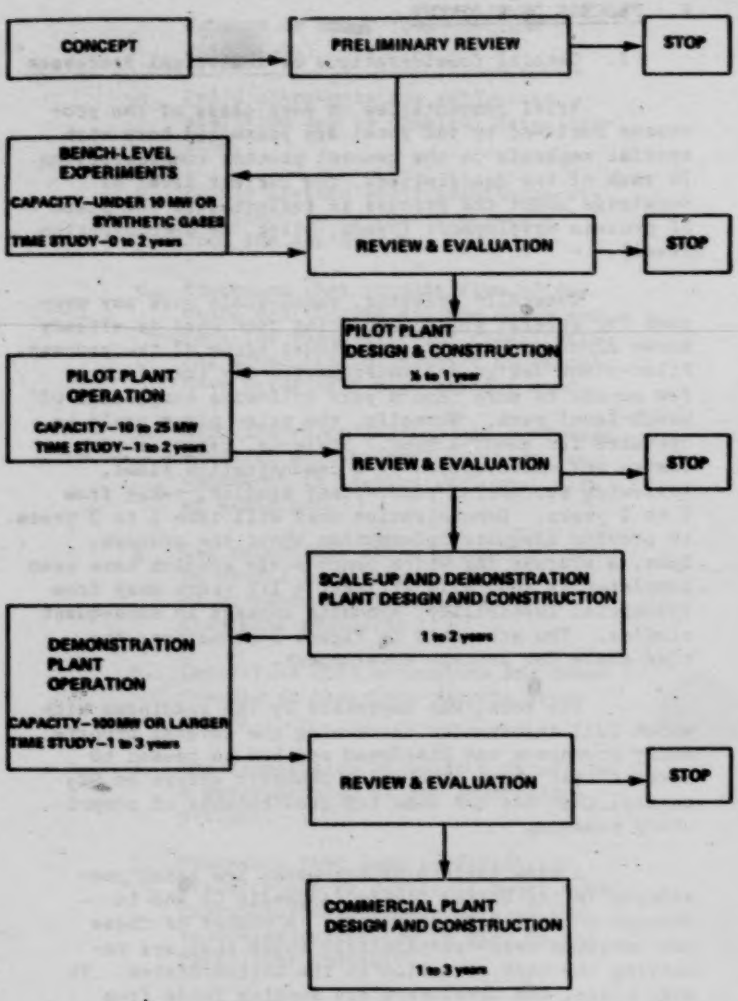

Figure 3. Time scale for process development.

the next level of feasibility investigation and reducing the time required for full-scale demonstration.

2. Precombustion Processes

Coal cleaning and coal gasification are processes that attempt to overcome the sulfur oxide emission problem prior to combustion. The processes have the potential advantage of removing the sulfur at higher concentrations than are present in the stack gas. They also provide for the recovery of sulfur or pyrite and would contribute to the conservation of this resource.

a. Coal Cleaning

Coal washing or beneficiation by present methods is limited to reduction of pyritic sulfur and can be expected to yield only a moderate increase in the supplies of low-sulfur coals. In some cases, sulfur emissions may be controlled by combining coal washing with sulfur removal from stack gases by the dry-limestone or other relatively inexpensive processes.

Coal beneficiation to reduce ash content has been a regular practice of the industry for years. Some pyrite is also removed, but only in the past few years has specific attention been directed toward sulfur removal by this procedure. The sulfur in many coals is present in about equal parts as pyrite and organic substances. Differences in the specific gravity of coal and pyrite are the basis for accomplishing sulfur removal; however, only part of the pyrite sulfur can be removed by gravity cleaning methods. The pyrite is present as nodules on cleat faces, and as disseminated small veins and crystals. In some coals, the larger pyrite particles may be partially freed by crushing and grinding the coal. Some types of coal are more easily cleaned than others, depending upon the manner and form in which the pyrite is present. Experiments with organic solvents, such as hexane, to remove the organic sulfur indicate that prohibitive costs would be involved.

The coal cleaning process produces a pyrite-rich reject as well as the cleaned coal. The reject stream may be further separated into a concentrated pyrite and a high-sulfur fuel. These may be used, respectively, for sulfuric acid manufacture and in a combustion unit with flue gas scrubbing or some other means of SO_2 control.

The Bureau of Mines and Bituminous Coal Research have had active programs in air cleaning and coal preparation for years. Pilot tests on air and water classification and other means of removing pyrite from coal have been made. Studies include the technology of pyrite separation, washability tests, evaluation of standard coal cleaning equipment, in addition to flue gas processing.

b. Coal Gasification

Present projections indicate that the cost of generating electricity from low-sulfur gas produced from coal will be greater than the cost of obtaining the same energy directly from coal. Coal gasification's potential will depend greatly on the availability of natural gas and on the cost of alternative methods for SO_2 control. Because gasification is potentially an alternative method of reducing SO_2 emissions to the atmosphere, the panel suggests that consideration be given to less sophisticated and possibly less costly gasification processes that would produce a relatively clean lower-heating-value gas, suitable for onsite use, but not of pipeline quality.

The Office of Coal Research has an active program for the development of pipeline gas and liquids from coal. While the manufacture of pipeline-quality gas from coal is not competitive at present, it appears that it may become so, as gas demand increases, natural gas reserves decline, and the technology of gasification processes improves in the next 5 to 10 years.

At present at least four processes are being considered:

1. Hydrogasification--Institute of Gas Technology

2. CO_2 Acceptor--Consolidation Coal Company

3. Two-Stage Super-Pressure Gasification--Bituminous Coal Research

4. Molten Salt Process--Kellogg Company

These processes require preliminary grinding, and those using lignite require drying. For coal hydrogasification, a mild air-oxidation pretreatment is used to avoid agglomeration in the hydrogasifier. The BCR process uses high pressure combustion to provide heat in the gasifier; the Kellogg process circulates hot molten salt to the gasifier; and the CO_2 Acceptor process employs the reaction of calcined dolomite with CO_2. Hydrogen is obtained by reacting char and steam. All processes require purification plus methanation to upgrade the gasifier effluent to gas of pipeline quality. During the purification step, sulfur is removed as an H_2S feed for a Claus plant.

The Institute of Gas Technology Hygas process is the nearest to commercialization and, assuming success in the pilot studies, will be commercially available in the late 1970's. IGT is starting up a 5-ton-per-day pilot plant, funded by the Department of the Interior Office of Coal Research, in Chicago for further study of the Hygas process. Only recently has attention been given by IGT to production of gas of less than pipeline quality for power plant fuel.

In addition to the research being supported by the Office of Coal Research, several companies are developing coal gasification processes of their own to produce either pipeline or sub-pipeline quality gas. It should be noted that low-heating value gasification processes will require sulfur removal from volumetric flows only slightly smaller than stack gas rates, thereby reducing the advantage of easier sulfur removal resulting from the higher concentrations.

3. Combustion Processes

The new combustion processes remove the sulfur during burning by methods that do not require extensive stack gas cleanup. Some of the more promising processes that offer the possibility of being brought to commercial acceptability in the later 1970's are discussed below. These processes also offer the possibility of sulfur recovery and the corresponding conservation of sulfur resources.

The combustion processes proposed for sulfur oxide control require new concepts of boiler design. The manufacturers and utilities have standardized boiler design to the extent that few major changes have been made in recent years. Additional effort will be required to obtain acceptance of these processes by industry since changes in manufacturing procedures and in operation will be necessary. The processes offer some of the more logical approaches to sulfur oxide emission control and deserve the extra level of support that will ensure their full consideration.

a. Fluidized Bed Combustion (FBC) is a new concept in boiler design and would be applicable only to new plants. The burning fuel is contacted with a fluidized bed of limestone particles which react with the sulfur. A portion of the bed is continuously removed and replaced with fresh limestone. Several FBC systems are being studied in England. The (British) National Coal Board is conducting research on atmospheric and pressurized systems. Esso Research Ltd. has been developing a two-stage FBC unit in which high-sulfur residual fuel oil is burned and sulfur values recovered. In the United States, the firm of Pope, Evans, and Robbins (under sponsorship of the Office of Coal Research and the National Air Pollution Control Administration) has conducted pilot plant work and studied the applicability of fluid bed combustion to industrial boiler systems. The National Coal Board projects that scale-up, from current laboratory testing, to a 20- to 30-MW single-stage atmospheric pilot unit can be completed by 1972.

b. The Black, Sivalls, and Bryson Combustion Process is a new concept in boiler design, in which sulfur oxide formation is prevented by the submerged partial combustion of coal in a bath of molten iron. The resulting carbon monoxide is burned above the molten bath. The sulfur is removed with the ash-slag and is subsequently recovered as sulfur. Black, Sivalls, and Bryson are conducting feasibility studies and have begun pilot plant design.

4. Limestone Processes

The limestone processes for sulfur oxide removal should be given priority in terms of research money and encouragement, because sufficient work has been done on these processes to suggest that they may become commercially acceptable sooner than any of the processes that produce salable products. Moreover, it appears that, for some applications, the net cost of throw-away processes may be less than for a recovery process. This is particularly true of a station that has been in operation for some time, since amortization of the cost of the control equipment would be over the remaining life of the plant, and the load factor of the plant would be lower in its later years.

Problems may arise with limestone because of limitations on the space available for disposal of waste products. In some locations, this could be expensive and tip the balance toward a recovery process. On the other hand, the dry-limestone process can be used intermittently for incident control, and thereby reduce the amount of material handled. This could be done in certain areas of high pollution levels where local control at specific times is needed.

The possibility that the limestone-based processes may solve an air pollution problem but create a water pollution problem is one reason that the panel endorsed NAPCA's plan to install plant-scale test facilities at TVA, where full consideration will be given to various ways of handling air and water pollution and solid wastes. The government effort has merit because the plans are to study the situation not only for dry-limestone but also for scrubber design

alternatives; this would expand the applicability of the limestone processes. In addition, the technology developed for SO_2 removal by limestone-wet scrubbing will contribute to the general knowledge of wet scrubbers, and this will be useful in other wet scrubbing processes.

The panel does not favor the dry- or wet-limestone processes exclusively, but merely as a stop-gap or a first line of defense. There are other processes that will have to be developed to provide more adequate control of emissions. Limestone injection technology seems nearest to industrial application and therefore deserves priority in the near term.

The limestone processes appear to be applicable to many existing power plants. Because they do not produce a salable product, the limestone processes should appeal to utilities not wishing to get into the chemical business. The lower capital costs make these processes attractive to the older plants operating with low-load factors. There is added cost for the additional fly ash removal, and there is a probable increase in particulate emissions resulting from the increased precipitator load for the dry removal process.

While the limestone processes are generally thought of as not producing a salable product, there is the possibility of recovering sulfur dioxide by heating the calcium sulfite portion of the recovered solids. With control of oxidation to sulfate, this could provide for recovery of most of the sulfur dioxide and reuse of the limestone. This area will also be covered in the TVA study.

a. Limestone-Wet Scrubbing was originally studied at Battersea in London, England, and at the Tir John Power Plant in Swansea, Wales, during the 1930's. In this early work 90 percent removal of SO_2 was obtained [20] confirming the technical capability of the process. However, the work also identified specific problems of low reliability, high maintenance and operating costs, corrosion, abrasion, scale deposit, solid waste disposal and loss of plume buoyancy.

Current studies in the United States and other countries are attempting to overcome these problems through improved process and equipment design, closer control of operating parameters, improved materials, systems optimization, and reliability.

Limestone-wet scrubbing may be added to existing plants without significant boiler modification. Limestone may be injected into the boiler as well as added to the scrubbing liquor. Solids disposal will be several times the normal fly ash disposal rate. The Combustion Engineering Company has recently built two full-scale units at the Meramec Plant of the Union Electric Company in St. Louis and at the Lawrence Plant of the Kansas Power and Light Company. Each unit is designed to handle all the flue gas from a 125-MW boiler. Both plants have had start-up troubles but are expected eventually to meet the design objectives of 83 percent sulfur removal and 98 percent particulate removal. However, Kansas Power and Light Company is proceeding with plans for a 430-MW power plant, using the limestone-wet scrubbing process. Problems of scrubber optimization and waste disposal may require several years of additional study and are further discussed at the end of this chapter.

b. Limestone-Dry Removal uses an electrostatic precipitator. The process may be added to existing plants. Reaction time and temperature requirements are such that the process may not be applicable to cyclone-fired boilers. Solids disposal problems will be several times the normal fly ash disposal rate. The Tennessee Valley Authority is installing a 175-MW demonstration unit at its Shawnee plant near Paducah, Kentucky.

5. Processes for Sulfur Recovery from Stack Gases

Several processes for recovering sulfur from the stack gas following combustion are at or near the demonstration level. These processes will recover the sulfur oxide and convert it into products for the chemical industry, such as sulfuric acid, hydrogen sulfide, sulfur oxides, and elemental sulfur.

Domestic reserves of sulfur are limited, and consideration should be given to their conservation. It would be desirable to *conduct a study of the long-range supply and demand situation with regard to the several alternative by-products to aid in establishing priorities for support of control and abatement technology.* Most of the processes reviewed rely on relatively straightforward chemical reactions and processing equipment. The major technical problems are related to the low concentration of SO_2 in large volumes of flue gas containing a variety of corrosive materials.

a. The Cat-Ox Process of Monsanto Company is a direct translation of the contact sulfuric acid process. Boiler modifications are needed as the converter uses gas at temperatures of 700° F to 900° F. The process has been successfully piloted (15-MW equivalent) at the Portland, Pennsylvania, station of Metropolitan Edison Company. Monsanto has proposed the pilot unit as a modular alternative to commercial-scale demonstration. It is especially applicable to high-sulfur fuels, such as coal-cleaning middlings and ore smelting. This process could be commercially demonstrated by 1973.

b. The Wellman-Lord Process is an add-on process and does not require boiler modifications. Sulfur dioxide is recovered from the stack gas by scrubbing and reprocessing the scrubbing solution. During 1969, a 25-MW pilot study was conducted at the Crane Station of the Baltimore Gas and Electric Company. W. R. Grace Company, the Bechtel Corporation, Potomac Electric Power Company, Delmarva Power and Light Company, and Potomac Edison Company also participated in this study. A commercial Wellman-Lord recovery plant is being installed to recover SO_2 from the stack gas of a contact sulfuric acid plant of the Olin Mathieson Chemical Corporation at Paulsboro, New Jersey.

c. The Esso-Babcock and Wilcox Dry Adsorbent Process requires boiler modification to provide 900° F gas. Regeneration of the adsorbent produces sulfur

dioxide for a sulfuric acid plant. A 2,000 CFM bench-scale unit is in operation, and a 25-MW pilot plant is planned. If this is successful, a demonstration unit costing approximately $7.5 million is planned, with the objective of developing a commercial process by 1973. Sixteen utilities in the midwest and eastern United States and Canada are cooperatively funding the project.

d. Magnesium Oxide Scrubbing is an add-on process in which the scrubber removes both sulfur oxides and particulates. Chemico proposes a central recovery plant to remove sulfur dioxide and recycle the magnesium oxide to the power plants. Chemico and Basic Chemicals are conducting pilot studies of the process.

e. The Formate Scrubbing Process is an add-on process in which the reprocessing of the scrubbing solution yields a feed gas for a Claus plant for sulfur recovery. Bench-scale studies have been conducted by Consolidation Coal Company.

f. Ammonia Scrubbing of stack gases can be done as an add-on process without boiler changes. Sulfur dioxide can be stripped from the scrubbing liquid, using heat, or the solution can be acidified with nitric, sulfuric, and phosphoric acids to produce various fertilizers. Bench-scale studies were made some years ago. The renewed interest in the process lies mainly in the decrease in the price of ammonia in recent years.

g. The Westvaco Char Process is an add-on process. A source of hydrogen is needed for regeneration of the adsorbent/catalyst char and to produce a feed stream for a Claus sulfur recovery plant. Pilot-level studies are being conducted by Westvaco.

h. The Molten Carbonate Process is intended mainly for new plants with modified boilers to provide the gas at 900° F. Reprocessing of the scrubbing melt produces a feed gas for a Claus sulfur recovery plant. Bench-scale studies have been made by Atomics International.

i. Sodium Bicarbonate Adsorption is an add-on process that removes both sulfur oxide and fly ash. Pilot-level studies have been conducted by Dow Chemical Company.

j. The Modified Claus Process is an add-on process and is an extension of the conventional Claus sulfur process. A source of hydrogen (natural gas) is needed for the process to recover sulfur. Princeton Chemical Research has conducted bench-scale studies of the process.

k. The Catalytic Chamber Process is a modification of the old lead chamber process and removes both sulfur and nitrogen oxides and produces sulfuric acid. It is an add-on process that requires some additional space. Bench-scale studies have been conducted by Tyco Laboratories.

l. The Ionics/Stone & Webster Process uses a scrubber and an electrolytic cell system to recover sulfur dioxide for subsequent sulfuric acid production. It is an add-on process that requires a significant amount of power. Pilot-level studies have been conducted by Ionics and Stone & Webster.

m. The Alkalized Alumina Process has received significant attention. Attrition of the alkalized alumina has been a continuing problem. Recent detailed engineering and cost analysis (by M. W. Kellogg) suggests that further work on this process is unjustified.

6. Scrubber Development

There is a wide variety of SO_2 removal processes that use scrubbers as the principal chemical contactor. Some, such as the lime scrubbing process, employ reactants that may cause scaling and plugging of equipment because of the precipitation of solids, while others, such as sodium salt scrubbers, use clear liquids containing no solids. Nearly all scrubber applications require corroision studies and materials evaluation. The problem is not simply a matter of

finding a single best scrubber for all applications, but to develop a scrubber technology for a variety of applications. Consequently, NAPCA plans to look at several scrubber types on a small scale in an effort to characterize process chemistry combinations and generate the background data necessary to select the best scrubber for the specific process. In this way scale-up would not be repeated for every promising process.

The proposal for work to be done by the TVA on the wet-limestone process involves a large development and testing effort on scrubbers. This same installation could conceivably be utilized with some modification to test other wet scrubber sulfur recovery processes, when technology reaches the stage at which testing on this scale is justified.

APPENDIX A

LIST OF PRESENTERS

The following organizations made presentations to the Panel on Control of SO_2 from Stationary Combustion Sources:

Babcock & Wilcox
Bituminous Coal Research, Inc.
Black, Sivalls, & Bryson, Inc.
Chemical Construction Corporation
Combustion Engineering, Inc.
Continental Oil Company
(Consolidation Coal Company, Inc.)
The Dow Chemical Company
ESSO Research and Engineering Company
Institute of Gas Technology
Ionics Incorporated/Stone & Webster
The M. W. Kellogg Company
McNally Pittsburg Manufacturing Corporation
Monsanto Company
National Air Pollution Control Administration
North American Rockwell Corporation
(Atomics International Division)
Office of Coal Research
Pope, Evans and Robbins
Princeton Chemical Research Company
Roberts & Schaefer Company
Tennessee Valley Authority
Tyco Laboratories, Inc.
Wellman-Lord, Inc.
WESTVACO

APPENDIX B

LIST OF CORRESPONDENTS

The following companies sent in material to the panel describing their activities and experience on control of SO_2 from stationary combustion sources:

Abcor, Inc.
The Air Preheater Company, Inc.
Air Products and Chemicals, Inc.
American Petroleum Institute
Basic Chemicals
The Carborundum Company
The Detroit Edison Company
Edison Electric Institute
Institute of Gas Technology
Joy Manufacturing Company
(Western Precipitation Division)
Kaiser Aluminum & Chemical Corporation
(Kaiser Chemicals Division)
The Kansas Power and Light Company
Nalco Chemical Company
Pennsylvania Electric Company
Precipitair Pollution Control, Inc.
Research-Cottrell, Inc.
Reynolds Metals Company
Reynolds, Smith and Hills
Slick Industrial Company
(Pulverizing Machinery Division)
Union Electric Company
United International Research, Inc.
Universal Oil Products Company
(Air Correction Division)
The Wheelabrator Corporation

APPENDIX C

UNITED STATES SO_2 POLLUTION CONTROL RESEARCH AND DEVELOPMENT*

Company	Type of Work
Abcor, Inc.	Aqueous absorption systems for SO_2
Air Products and Chemicals, Inc.	Dry process for SO_2 removal
American Iron and Steel Institute	Studies of sulfur pollution control from various iron and steel manufacturing steps
Argonne National Laboratory	Reduction of atmospheric pollution by the application of fluidized bed combustion
Babcock & Wilcox	Magnesium oxide scrubbing system and other SO_2 removal processes
Basic Chemicals	Magnesium slurry scrubbing (in conjunction with Chemico)
Bituminous Coal Research, Inc.	Use of limestone or dolomite for SO_2 removal from coal-burning boiler flue gases
Bituminous Coal Research, Inc.	Removal of pyritic sulfur from coal
Black, Sivalls, & Bryson, Inc.	Coal gasification in molten iron; sulfur removal in slag
The Carborundum Company	Limestone injection with wet scrubbing or bag filtration
Chemical Construction Corporation	Various projects for SO_2 control from sulfuric acid plants and power plants
Combustion Engineering, Inc.	Limestone injection-wet scrubbing process

*Compiled by NAPCA, March 1970.

Company	Type of Work
(Kansas Power and Light Company)	Demonstration of Combustion Engineering limestone injection-scrubbing process
(Union Electric Company)	Demonstration of Combustion Engineering limestone injection-scrubbing process
Consolidation Coal Company, Inc.	Flue gas scrubbing, fluidized combustion in a lime bed, and pyrite removal from coal
The Detroit Edison Company	Limestone scrubbing, ammonia injection
The Dow Chemical Company	Gas-phase removal of SO_2 with solid alkaline materials
Edison Electric Institute	Dispersion characteristics of stack effluents, development of a formula for stack design
ESSO Research and Engineering Company	B&W-Esso proprietary process for SO_2 removal
General American Transportation Corporation	Catalytic reduction of SO_2 to sulfur
Hydrocarbon Research, Incorporated	Catalytic hydrogenation of fossil fuels
Illinois Institute of Technology Research Institute	Oxidation and reduction catalysts
Institute of Gas Technology	Coal Gasification
Ionics Incorporated/ Stone & Webster	Regenerable aqueous scrubbing system for SO_2 removal and recovery (Stone & Webster-Ionics process)
Kaiser Chemicals	Improved dry sorbent for SO_2 removal
The M. W. Kellogg Company	Undisclosed process for power plant SO_2 removal
Monsanto Company	Catalytic oxidation of SO_2 with recovery of sulfuric acid
(Pennsylvania Electric Company)	Development of Monsanto catalytic oxidation process
(Air Preheater Company)	
(Research-Cottrell)	

Company	Type of Work
Nalco Chemical Company	Dry sorbent for SO_2
Petroleum Industry (Source: API)	Industry-wide R&D for sulfur oxides control
Pope, Evans & Robbins	Control of gaseous emissions from coal-fired fluidized-bed boilers
Precipitair Pollution Control, Inc.	Gas-phase removal of SO_2 with solid alkaline materials, and collection with fabric filters (cooperative work with Southern California Edison)
Pulp and Paper Industry (Source: NCASI)	Sulfur oxides control from sulfite and kraft pulping processes
Research-Cottrell, Inc.	Scrubbing equipment development
Reynolds Metals Company	Dry sorbents for SO_2 removal
Reynolds, Smith, and Hills	Scrubbing process for flue gas SO_2 removal
Slick Industrial Company	Dry SO_2 sorbent development
Southern California Edison Company	Gas-phase removal of SO_2 with solid alkaline materials, and collection with fabric filters
Stone & Webster	Regenerable aqueous scrubbing system for SO_2 removal and recovery (S&W-Ionics process)
United International Research, Incorporated	Regenerable scrubbing process removal; SO_2 converted to H_2SO_4
U.S. Bureau of Mines-Morgantown	Study of corrosion/erosion and of coal type during fluidized bed combustion
U.S. Stoneware Company	Process for SO_2 control from sulfuric acid plants
Universal Oil Products	Dolomite slurry scrubbing; catalytic hydrogenation of fuels

Company	Type of Work
Wellman-Lord, Incorporated	R&D of regenerable wet scrubbing process at Lakeland, Florida, and Tampa Electric, plus direct reduction of SO_2 to sulfur
Tampa Electric Company	Pilot study of Wellman-Lord process, contributed to Stone & Webster
(Bechtel Corporation)	Demonstration plant of Wellman-Lord process at Baltimore Gas and Electric power station
(Baltimore Gas and Electric Company)	Demonstration plant of Wellman-Lord process at BG&E power station in Baltimore
(Potomac Electric Power Company)	
(Delmarva Power and Light Company)	
(Potomac Edison Company)	
Western Precipitation Group (Joy Manufacturing Company)	Scrubbing equipment development
Westinghouse R&D Center	Evaluation of the fluidized bed combustion process
Westvaco	Adsorption of SO_2 by activated carbon
The Wheelabrator Company	Scrubbing equipment development
Wisconsin Electric Power	Lime scrubbing, other aqueous scrubbing systems

APPENDIX D

FOREIGN SO_2 POLLUTION CONTROL RESEARCH AND DEVELOPMENT*

Company	Type of Work
Australia	
Commonwealth Science Industrial Research Organization	Fluidized bed combustion
Czechoslovakia	
Research Institute of Inorganic Chemistry	Ammonia scrubbing of SO_2 effluent
Czech acid plant scrubbing	Ammonia scrubbing on H_2SO_4 plant tail gas
Fuel Research Institute	Fluidized bed combustion
Institute of Mines	Desulfurization of coal
England	
Esso Research Center	Fluidized bed combustion of oil
National Coal Board Coal Research Establishment	Fluidized bed combustion of coal
BCURA Industrial Labs	
LHF Patented Process Esso Research	Desulfurization of coal
Bankside and Battersea Process	Alkaline water scrubbing on Thames River
France	
Societe Nationale Des Petroles	Catalytic oxidation of flue gas
D'Aquatane (joint project with Halder Topsoe of Denmark)	
Ugine Kuhlmann-Weirtam Process	Ammonia scrubbing of flue gas
Societe Anonyme Activit Neyric	Fluidized bed combustion Desulfurization of coal

*Compiled by NAPCA, March 1970.

Company	Type of Work
Germany	
Bayer Double Contact Process	Two-stage catalytic oxidation of H_2SO_4 tail gas
Bischoff Process	Lime/Limestone scrubbing of flue gas
Lurgi Sulfacid Process	Wet char sorption of SO_2 from effluent
Activated Carbon Adsorption Bergbau-Forschung	Wet char sorption of SO_2 from effluent
Activated Char Sorption Bergbau-Forschung	Dry char sorption of SO_2 from gaseous effluent
Grillo Process	Sorption by proprietary mixture of metal oxides
Siemens-Schuchert Process	Sorption on iron oxides in silica gels
Holland	
Shell CuO process	Sorption on proprietary mixture of copper based metal oxides
NVCP (Nederlandsch Verkoopkantoor voor Chemische Producten N.V.)	Hydro desulfurization of oil
Italy	
University of Cagliari	Desulfurization of coal
Japan	
Kiyoura Ammonium Sulfate Process	Catalytic oxidation of flue gas
Nippon Kokan Ltd.	Lime/Limestone scrubbing of flue gas
Japan Engineering and Construction Co. (JECCO)	Lime/Limestone scrubbing of flue gas
Showa-Denko Process	Ammonia scrubbing
Hitachi Activated Carbon Process	Wet char sorption of SO_2 from effluent
Central Research Institute of the Electric Power Industry	Dry limestone injection for SO_2 control of flue gas
Resources Research Institute	Dry limestone injection for SO_2 control of flue gas
Mitsubishi DAP-Manganese Process	Manganese oxide sorption
Kanagawa	Aqueous scrubbing

Company	Type of Work
Poland	
Dry Ammonia Injection	Injection of gaseous ammonia into flue gas
Sweden	
BAHCO Lime-scrubbing Process	Lime/Limestone scrubbing of flue gas
U.S.S.R.	
Wet Limestone scrubbing at Kusnetsk Abagur Plant	Lime/Limestone scrubbing
Ammonia and sodium carbonate scrubbing-Voskresenskij Chemical Industry	Ammonia scrubbing
I.M. Gubkin Institute of Petroleum and Others	Fluidized bed combustion
Academy of Science	Desulfurization of coal
Lensovet Technological Institute	Desulfurization of oil
Yugoslavia	
Institute of Mines	Desulfurization of coal

INDEX

WEST CENTRAL REGION

POWER SURVEY

1970–1990

A REPORT

to the FEDERAL POWER COMMISSION

prepared by

THE WEST CENTRAL
REGIONAL ADVISORY COMMITTEE

SUMMARY

The West Central Region comprises about one-fifth of the conterminous United States and includes about 14% of the population. The region is outlined on the map, Figure 1, below.

Figure 1

The region extends from Lake Michigan and the Illinois-Indiana state line on the east to an irregular line through eastern Montana, Wyoming and western Nebraska. In the north-south direction, the area extends from the Canadian border to an irregular mid-continent line including most of Nebraska, northern Missouri and all of Illinois. The West Central Region corresponds to FPC power supply areas 13, 14, 15, 16, 17 (excluding the Kansas City area), 26, 27, 28 and 40.

The principal load centers are located in the eastern half of the region, and are concentrated in the metropolitan areas of Chicago, Milwaukee, Minneapolis-St. Paul, Omaha, Des Moines, Quad Cities and St. Louis. The western portion of the region is an area of low population density and corresponding low load requirements with few major load centers.

The non-coincident peak load for 1965 in the West Central Region was 24,290 megawatts and the projections are 35,930 megawatts for 1970, 70,610 megawatts for 1980, and 131,680 megawatts for 1990 as detailed in the following tabulation. This indicates a load in 1990 of about five and one-half times the 1965 load compared to an anticipated population growth of 40 percent. The total energy used per person is expected to increase from 4,800 kwhr in 1965 to 18,500 kwhr in 1990.

Figure 2
LOAD GROWTH IN THE WEST CENTRAL REGION
(MEGAWATTS)

PSA Area	1965	1970	1980	1990
13	3,344 (W)	4,660 (W)	8,510 (S)	15,290 (S)
14	6,733 (S)	10,070 (S)	19,810 (S)	37,020 (S)
15	2,943 (S)	4,530 (S)	9,720 (S)	18,770 (S)
16	2,984 (W)	4,280 (S)	9,210 (S)	18,350 (S)
17	2,471 (S)	3,730 (S)	7,160 (S)	13,120 (S)
26	649 (W)	960 (W)	1,820 (W)	3,390 (W)
27	627 (W)	910 (W)	1,900 (W)	3,680 (W)
28	1,444 (S)	2,220 (S)	4,390 (S)	8,070 (S)
40 (Excl. EEInc)	2,529 (S)	3,835 (S)	7,355 (S)	13,255 (S)
40 (EEInc only)	566 (W)	735 (W)	735 (S)	735 (S)
Total (Non-coincidental)	24,290	35,930	70,610	131,680
Total (Non-coincidental summer season)	23,920	34,830	69,780	130,240

(S) denotes summer peak
(W) denotes winter peak

The task force based these load projections on a pooling of the independent judgments of the utilities in the region. This current forecast for the region as a whole is higher than that appearing in

the 1964 National Power Survey. As an example, the 1980 forecast of 70,610 mw compares with the previous forecast of 61,050 mw, an increase of about 15%. The principal reason for this increase is the continued rapid growth in the economy and growth in utility sales and peak loads during the period subsequent to the 1964 National Power Survey effort.

Substantial fossil fuel resources are located within the region, with approximately 370 billion tons of recoverable coal reserves believed to exist. Additionally, a recent report indicated additional reserves could amount to 225 billion tons of recoverable coal reserves in unmapped and unexplored areas. Although the bituminous coal resources have made a considerable contribution to the supply of electric energy to date, the sub-bituminous coal supply in Montana and Wyoming and the lignite coal reserves in the Dakotas and Montana are receiving new attention with the advent of unit-train transportation and improved burning technology. As a matter of interest, one county in North Dakota contains 71 billion tons of lignite coal. This is the largest tonnage for coal bearing counties in the nation.

The natural gas reserves in the region comprise less than 1% of the total reserves in the United States. The crude oil and natural gas liquid reserves approximate 2% of the total liquid hydro carbon reserves in the United States.

The fossil fuel survey indicated that the average price of coal f.o.b. mine has increased about 10% for coal obtained from Illinois, the highest producing coal area in the region, during the period 1961-1966. Rail transportation has predominated in the movement of coal in this region, and within recent years the cost of coal transported by rail has been reduced substantially on selected movements of coal shipped by unit train. During 1966 about 22% of coal for the region was shipped by unit train, 27% by rail-barge, and 11% by rail-lake.

Large investor-owned utilities are the principal suppliers of electric energy to the major metropolitan centers in the eastern portion of the region. Rural electric cooperatives are well established throughout the entire region and the generation-transmission type (G & T) cooperatives are functioning in Iowa, Minnesota, North Dakota, South Dakota and Wisconsin. Public agencies are the principal suppliers of electric energy in Nebraska. The largest numbers of municipal systems in the region are found in PSA 17 (188), PSA 28 (138), and PSA 16 (110).

In the West Central Region there are 85 investor-owned systems, 261 cooperatives, two Federally-owned systems, and 701 publicly owned systems, comprised mainly of municipal systems and public power districts. Investor-owned companies serve 83.8 percent of the energy requirements in the region, the cooperatives 2.6 percent and the public agencies (other than Federal) 6.9 percent. The Federal Government generates 6.7 percent of the electric energy in the region, its output being sold principally to municipalities, public power districts and cooperatives. In 1965 about 38 percent of all the power generated by G & T cooperatives in the United States was produced in the West Central Region with cooperatives in PSA 16 alone accounting for about one-half of this amount.

The five largest of the 85 investor-owned electric systems supply nearly 60 percent of the electric loads in the region. Commonwealth Edison Company of Chicago alone accounts for about 27 percent and Union Electric Company of St Louis for about 11 percent of the regional load. The largest municipal system in the region is Springfield, Illinois, which had a peak load in 1967 of 170 megawatts or about one-half percent of the total regional load.

Public power districts are the principal suppliers of electric power in Nebraska. Many towns in the state are served by municipal systems. Some of the municipalities provide their own generation but most obtain their power from public power districts which carry out the principal generation and transmission functions in the state. Public power districts and cooperatives in Nebraska are also the principal agencies for the distribution of power. There are no investor-owned utilities providing electric service in Nebraska.

The Bureau of Reclamation is the marketing agency for hydroelectric power from Federal projects located in the Missouri River Basin. The power is marketed largely to customers having preference under Federal Law, i.e., municipal systems, public power districts and cooperatives, over a transmission network which generally has a voltage of 230 kilovolts. Numerous wheeling arrangements have been made by the Bureau with utilities in the area for delivery of power to such preference customers.

There is a total of 1,049 electric systems serving the region. With the exception of 71 isolated systems comprising .57% of the total service, all the systems are interconnected and operate in parallel with the vast majority of electric utilities in the United States. By 1970, the interconnecting transmission system will be overlaid with a 345 kv transmission system in the eastern

half of the region and an overlaying EHV system in the western half will have been begun. The pattern of transmission development anticipates that the 345 kv system in the eastern half will be substantially augmented during the 1970-1980 period and a 765 kv system will have been started. In the western half of the region the transition to a 500 kv system will be initiated. By 1990, several east to west 765 kv transmission lines are anticipated with their extension through western Minnesota, the Dakotas and the state of Nebraska at 500 kv to interconnect with the western systems.

Consideration of probable increasing fossil fuel costs, increasing concern for air pollution, fossil fuel transportation difficulties, and the anticipation of relative decreasing nuclear fuel costs with the development of fast breeder reactors have resulted in a considerable emphasis on nuclear generating plants. Although about 90% of the electric energy produced in the region is presently supplied by fossil-fuel generation, by 1990 nuclear generating capacity is anticipated to comprise 57% of the region's capacity. Nuclear generation is expected to supply nearly 70% of the region's energy requirements by that time. While the quantity of coal burned annually is indicated to increase from 51 million tons in 1966 to 69 million tons in 1975, the regional use of coal apparently will remain relatively constant at about 65 million tons for the remainder of the study period.

Generating capacity of 79,832 megawatts is projected by 1980 to supply a non-coincident summer peak of 69,780 mw with a reserve of 15.6%. By 1990, generating capacity of 151,041 megawatts is projected to cover a non-coincident summer peak of 130,240 megawatts reflecting a reserve of 16.6%. An importation of 800 mw of hydro power from Canada is included in each of these reserve calculations. Additional reserve of an undetermined amount exists because of the diversity of load between utilities within the season. About half of the 1990 capacity is shown to be in units of 800 megawatts or larger. Generator unit size up to 2000 megawatts and total plant size up to 4000 megawatts are included.

There are six power pools within the region and three major regional coordinating groups. These organizations permit the coordination of planning of transmission and generation and the coordination of operating these facilities. Such coordination is made possible through the direct work of committees and task forces comprised of representatives of individual utilities on the pool level, and of representatives of pools and areas on the regional level. Two offices have been established to provide coordination of hour-to-hour and day-to day operations.

Additionally, liaison established with contiguous regions provides continuity in the development of interconnections at the boundaries of these organizations and in the operating of mutually-affected facilities. As further coordination develops in increasing depth, it is anticipated that a single regional coordinating organization will evolve with the major planning and operating responsibilities being carried on by five area-wide groups. The interworking between these five groups then will be coordinated within the one principal organization.

II

INVENTORY OF FOSSIL FUEL RESOURCES

INTRODUCTION

The purpose of this report is to update the 1964 National Power Survey, Vol. II, Advisory Committee Report No. 21 on Fuels for Electric Generation, prepared by the Fuels Special Technical Committee.

In updating Report No. 21 we have not attempted to change or modify the extensive and authoritative background material in that report, which represents the best advance thinking on industry fuel problems by some of its foremost members. Instead we have supplemented that report where changes have occurred in the price of fuel, the cost of transportation and methods of transport.

The West Central Region fossil fuel reserves are reported in detail by individual counties in each state. The reserves are tabulated by class of reserves as to whether they are "measured," "indicated" or "inferred" and by thickness of the coal beds. Measured reserves are those for which tonnage was computed from direct measurements. Indicated reserves are those for which tonnage was computed partly from specific measurements and partly from responsible assumptions based on available data and geologic evidence. Inferred reserves are those for which quantitative estimates are based on a broad knowledge of the character of the bed or the region, but for which there are few, if any, actual measurements. This detailed information on coal reserves should be useful to system planners in selecting future sites for large thermal power plants.

Other task force committees have prepared reports on load projections, types of generation, air pollution and nuclear power; therefore, this report does not include information on those subjects. If the reader desires information on productive capacity of the coal industry, future projected prices of various fuels or other related information regarding fuels, it is suggested he consult the report of Fuel Resources, Requirements and Costs for Electric Generation in the Eastern United States which was prepared by a committee that included representatives from the Federal Power Commission, the Bureau of Mines and the Office of Oil and Gas, Department of the Interior.

SUMMARY

During the period 1970-1990, electric generation will be dependent upon five basic forms of energy -- coal, gas, oil, hydro, and nuclear. This report is concerned primarily with fossil fuels. The availability of approximately 370 billion tons of recoverable coal reserves in the West Central Region is more than sufficient to meet the electric utilities' requirements in this region through the year 2000. A recent report indicates additional reserves in this region could amount to 225 billion tons of recoverable coal reserves in unmapped and unexplored areas.[1] Coal, however, will be faced with continuing pressures from other forms of energy, and based on present trends the most significant competition will be from nuclear energy.

Mechanization and handling of coal at the mine will continue to improve. Some of the new developments in underground mining in recent years have been the use of a mobile bridge conveyor which has increased the productivity from a continuous miner substantially, the underground push button miner, the installation of long wall mining equipment, and the application of computer simulation techniques.

In determining the type of fuel to be used for electric generation a number of factors have to be reviewed and evaluated, each of which will have a bearing on total fuel costs for any one location. The cost of transportation, anti-air pollution devices, storing, handling and disposing of the fuel product are economic factors which can make a low cost fuel the most expensive fuel. Therefore, while a general picture can be drawn of the availability and price of fuels, the final determination in selecting a fuel or fuels for a particular plant must be based on the specific facts pertinent to that plant and its location.

A fossil fuel survey questionnaire was sent to twenty-six electric utilities which consume approximately 90 percent of the coal used for electric generation in the West Central Region. The questionnaire inquired as to producing district, tonnage burned, f.o.b. mine price, average BTU per lb. received, cents per million BTU f.o.b. mine, methods of transportation used, freight rate, haulage distance, and tonnage per shipment.

This survey indicated that in the period 1961-66 the average price of coal f.o.b. mine has increased from 15.03 to 16.57 cents per million BTU or an increase of 10.18 percent on the coal obtained

1. Averitt, Paul, 1968 U.S. Geological Survey.

in District 10 (36 million tons of 46 millions tons reported for the region).. The average annual increase in the cost of District 10 coal in the five year period 1961-1966 amounts to 1.9 percent per year. Due to the less significant tonnages reported in relationship to tonnage produced, a comparison of the price increases for coal obtained from other districts is not shown.

Rail transportation in the past has predominated in the movement of coal in this region, and within recent years the cost of coal transported by rail has been reduced substantially on selected movements of coal shipped by unit train. Based on the 46 million tons reported in the survey for the year 1966, approximately 10 million tons, or 21.8 percent, were shipped by unit train, 12,200,000 tons, or 26.6 percent, were shipped by rail-barge, and 5,280,000 tons, or 11.5 percent, were shipped by rail-lake. The amount of coal shipped by conveyor and captive shuttle train during the period 1970-1975 will increase by 11,000,000 tons versus a 7,000,000 ton increase for unit train shipments.

The average rail freight cost in the West Central Region for coal shipments in 1966 amounted to $1.97 per ton on a tonnage of 23,500,000 tons, or approximately 46 percent of the coal consumed in this region. The unit train freight rates reported in the survey when compared on a basis which considers railroad ownership of all equipment indicates that the mills per ton mile range from 10.3 mills per ton mile for an 85 mile haul to 7.2 mills for a 138 mile haul and down to 5.0 mills for a 355 mile haul.

Past projections indicated that unit train freight rates could level out at a cost of 4 mills per ton mile for hauls between 350 miles and 600 miles.[2] However, no hauls of 400 to 500 miles at 4 mills were reported. The inability of the utilities to obtain a lower cost than 5 mills per ton mile is partially substantiated by the fact that as of the present date between now and 1975 approximately 10,000 megawatts of nuclear capacity is planned or considered for installation in the West Central Region.

In the five year period 1961-1966 the consumption of gas for thermal electric generation increased from 0.223 to 0.260 trillion cubic feet or at an average annual rate of 3.11 percent compared to a 7.73 percent average annual increase in coal consumption in the same period. The average cost of gas for the region in the same period increased from 25 to 25.3 cents per million BTU or by 1.2 percent.

2. 1964 National Power Survey, Vol.2, Advisory Report No. 21, Pg. 338

Table A, page II-5, indicates the electric generation produced by coal fired plants in the West Central Region will increase from 124.8 billion Kwh in 1970 to 155.3 billion Kwh in 1990 and nuclear generation will increase from 17.5 billion Kwh to 489.1 billion Kwh in the same period. Table B, page II-5 indicates coal consumption will increase from 60.4 million tons in 1970 to 65.7 million tons in 1990.

Table 1, page II-11, lists the remaining coal reserves in the West Central Region by percent sulfur content and approximately 72.7 percent of the reserves in the region contain 1.0 percent or less sulfur. However, most of these low sulfur coal reserves are located in the States of Montana and North Dakota and most of the coal consumed in the region is obtained from the State of Illinois.

Table 2, page II-12, indicates the coal consumed for electric generation in the West Central Region in 1966 had an average sulfur content of 2.8 percent which is slightly more than the 2.3 percent average sulfur content of all coal consumed by the electric utilities in the United States.

The growing demand for air pollution abatement regulations has contributed to a major shift from the use of coal for electric generation to nuclear energy. In the West Central Region in 1966 approximately 72 percent of the electric generation was produced in coal fired plants and 1 percent by nuclear plants. Present projections illustrate that by 1990 approximately 22 percent of the electric generation in the region will be produced in coal fired plants and 70 percent by nuclear plants.

The natural gas reserves in the West Central Region as of December 31, 1966 amounted to 1.33 trillion cubic feet or less than one percent of the total reserves in the United States. Based on the projected United States cumulative natural gas requirements for the period 1966 to 1990 of 680 trillion cubic feet the reported reserves of this region could supply only 0.20 percent of these requirements.

The oil consumption in the West Central Region represented less than one percent of the total fuel consumption for the region. The crude oil and natural gas liquid reserves in the region amount to 0.813 billion barrels or approximately 2 percent of the total liquid hydrocarbon reserves in the United States.

In the State of Illinois as of July 1, 1965, the latest revised estimates of coal remaining in the ground totaled 140,700 million

Hydro		6.3		5.9		6.0		6.1		6.1		6.4
Total		79.1		89.8		125.5		149.5		213.1		394.8

Note: Fuel quantities are based on kilowatthour generation by fuels and weighted average heat rates, respectively, and were computed using the following conversion factors: 10,730 Btu per pound of coal; 143,000 Btu per gallon and 42 gallons per barrel of oil; 1,013 Btu per cubic foot of gas. The oil and gas equivalents per ton of coal are 3.33 barrels of oil and 21.3 MCF of gas, respectively. The amount of electric generation produced by coal thermal generation increases from 1975 to 1990 but fuel requirements decrease due to the improvement in the weighted average heat rate. Fuel consumption by type of fuel in the West Central Region will vary from the quantities indicated for the period 1970-1990 based on the future level of the national economy, industrial growth in the region, air pollution abatement regulations, fuel transportation cost, the price relationship of various fuels, regulatory restrictions, and the quantities of energy interchanged with other regions.

Footnote A
Fuel quantities in millions of tons of coal, barrels of oil and MCF of gas.

tons in reserves, of which 63,900 million tons are classed as measured and indicated and 76,800 million tons as inferred, all of which is of bituminous rank. The reserves are well distributed over an area of 38,000 square miles or 67 percent of the State's area in 78 counties of the 102 counties in Illinois. The minimum thickness of coal considered in preparing this estimate was 28 inches, except for areas of strippable coal where an average thickness of 18 inches was used.

Coal seams in Illinois are at depths ranging from a few feet to several hundred feet below the surface. Ages ago, the coal bearing formations were downfolded into a huge spoon-shaped basin centered in the southeastern part of the State. As a result, the beds minable by underground methods lie at the center of the basin while along the outer rim in a total of 40 counties, approximately 19,000 million tons of strippable coal lie near enough to the surface to be recovered by strip mining.

Tonnage figures alone, however, cannot demonstrate the full importance of Illinois coal reserves. The thickness of the beds is also extremely important since this aspect has a bearing on mining methods and, therefore, productivity. Most of the remaining coal reserves are in coal beds thick enough to permit effective mechanical mining.

The estimated original coal reserves of Iowa total 7,236 million short tons, of which 3,500 million tons are classed as measured and indicated reserves and 3,735 million tons are classed as inferred. A total area of about 1,316,040 acres in 37 counties was included in the reserve calculations; an additional area of about 1,291,830 acres in 44 counties is indicated by the currently available information to be favorable for the presence of coal beds more than 14 inches thick. The total recorded coal production of Iowa through 1963 is about 356 million tons. Assuming that for each ton of coal produced another ton has been made unrecoverable, the remaining reserves of the State are about 6,524 million tons.

Past estimates of the coal resources of Iowa were highly generalized and were based solely on an assumed total area underlain by coal of potential economic interest and on an assumed average thickness of coal within that area. The estimate of Campbell and Parker (1909), the most frequently quoted, of 29,160 million tons included coal 14 inches or more thick in an area of 12,560 square miles. The present detailed estimate by Landis (1965) is smaller than the older generalized estimates and covers a much smaller area. This estimate of Iowa coal reserves is on a bed-by-bed

original reserve basis. The ratio is about one-fourth as much reserves in about one-sixth as much area.

About one-third of Missouri is underlain by bituminous coal-bearing strata, and coal has been mined in 55 of the 63 counties in which it occurs. Coal deposits occur in an area of some 24,000 square miles extending northeastward across the State from Jasper County to Clark County. The estimated original coal reserves of Missouri total 23,977 million tons.

In the years since the Hinds (1912) estimate of 79,393 million tons was made, stratigraphic studies have indicated that many of his correlations of coal beds were in error and that the persistence in thickness which he assumed cannot be demonstrated in many localities. Coal beds thin and thicken from one area to another and in many instances in very short distances. An additional factor of considerable importance in the area north of the Missouri River is that glacial drift occupies the position of coal beds in many places. Details of this relationship can be established only by drilling or mining but, in general, considerable areas are affected.

A re-evaluation of Missouri's original (before mining) coal resources was made by Searight (1966) on a county-by-county basis. Current information does not support the large resources indicated by Hinds, and these have consequently been adjusted downward. In some cases, only 10 percent of the previous estimate has been retained, and others have been cut to as little as one percent of the earlier estimate. The total tonnage represented in the present estimate of 23,977 million tons is less than one-third that of 1912 estimate figures. The total cumulative tonnage mined in the period 1840 through 1967 has been approximately 313 million tons. The coal remaining is, therefore, estimated to be approximately 23,335 million tons.

The original coal reserves of Montana total 222,047 million tons as estimated by Combo and others (1949). This estimate includes 2,363 million tons of bituminous coal, 132,151 million tons of subbituminous coal, and 87,533 million tons of lignite. The reserves were estimated according to standard procedures of the U.S. Geological Survey with several minor exceptions as follows: for bituminous coal the thickness categories used were 14 to 24 inches, 24 to 36 inches, and more than 36 inches, instead of the standard categories of 14 to 28 inches, 28 to 42 inches, and more than 42 inches, which were established after the Montana work was underway. For subbituminous coal and lignite standard categories of 2½ to 5 feet, 5 to 10 feet, and more than 10 feet were used.

The Montana coal fields cover 35 percent of the total area of the State. Reserves are present in 35 out of 56 counties, but are concentrated largely in the Fort Union region and the Powder River Basin in the eastern part of the State. Big Horn, Powder River, and Rosebud Counties alone contain more than half the total in the State. For the past several years considerable exploration has been conducted by mining and petroleum companies and currently (April 1967) revised estimates indicate the presence of deposits of strippable reserves totaling about 8 billion tons.

The original lignite reserves of North Dakota, as estimated by Brant (1953), total 350,910 million tons of which 9,522 million tons are classed as measured, 50,120 million tons as indicated, and 291,268 million tons as inferred. The reserves were estimated according to the standard procedures of the U.S. Geological Survey. All the lignite included in the estimate is less than 1,200 feet below the surface and about 70 percent of the total reserves are less than 500 feet below the surface.

The reserves are well distributed over an area of 28,000 square miles in 23 counties in the western half of the State. Of several counties with large reserves, Dunn County is conspicuous in containing 71 billion tons or about one-fifth of the State total. This is also the record reserve tonnage for coal-bearing counties in the United States.

The original lignite reserves of South Dakota, as estimated by D. M. Brown (1952), total 2,033 million tons, all of which is less than 1,000 feet below the surface. The reserves were estimated according to standard procedures of the U.S. Geological Survey. The lignite reserves are concentrated in six counties in the northwestern part of the State. Harding County contains nearly 84 percent of the estimated reserves, but most of past production has been obtained from Dewey and Perkins Counties.

INVENTORY OF FOSSIL FUEL RESOURCES

During the period 1970-1990, electric generation will be dependent upon five basic forms of energy -- coal, gas, oil, hydro, and nuclear. This report is concerned primarily with fossil fuels. The availability of approximately 370 billion tons of recoverable coal reserves in the West Central Region as shown in Figure 1 and listed in Table 1 are more than sufficient to meet the electric utilities' requirements through the year 2000. Coal, however, will be faced with continuing pressures from other forms of energy, and based on present trends the most significant competition will be from nuclear energy.

In determining the type of fuel to be used for electric generation a number of factors have to be reviewed and evaluated, each of which will have a bearing on total fuel costs for any one location. The cost of transportation, anti-air pollution devices, storing, handling and disposing of the fuel product are economic factors which can make a low cost fuel the most expensive fuel. Therefore, while a general picture can be drawn of the availability and price of fuels, the final determination in selecting a fuel or fuels for a particular plant must be based on the specific facts pertinent to that plant and its location.

During the past twenty years the coal industry has contributed a great deal to the stability of fuel prices. Mechanization of the mines has enabled the industry to either reduce or at least maintain within reasonable limits the price of its product, in spite of continuing increases of over-all price indexes. During the period 1970-1990 it is expected that there will be continuing improvement in the mechanization and handling of coal at the mine. Some of the new developments in underground mining in recent years have been the use of a mobile bridge conveyor which has increased the productivity from a continuous miner substantially, the underground push-button miner, the installation of long wall mining equipment, and the application of computer simulation techniques.

Although coal is available in sufficient quantities in the West Central Region to supply the entire energy requirements of the electric utilities in this region, competition will determine the extent to which coal will penetrate each market.

temperature to 86°F. Cooling towers are included in the design of two large nuclear plants presently under construction in anticipation of state agency temperature limitations of 86°F. for mixed water or 5° over ambient. Capital costs for cooling facilities to date are estimated at $10,000,000 for plants totaling 2700 megawatts.

One utility in the area is constructing a 20 megawatt plant utilizing a recently developed air cooled condenser. This plant is to be a prototype for larger plant installations now under consideration. Because this type of facility eliminates the need for large quantities of cooling water, it may provide greater freedom in the siting of moderate size generating facilities.

In addition to state and local agencies, the Air Quality Act of 1967 introduces a new factor. The Secretary of Health, Education, and Welfare is to designate air quality regions and issue criteria and control technology documents. The governors of states involved will have approximately nine months to draw up standards acceptable to HEW and another six months to establish a method of control for the region. Additional research and development of control technology is being funded under the Air Quality Act, but to date the control strategies commercially available to the utilities are largely the use of precipitators and high stacks.

The concern of Wisconsin companies for proper and effective control of air and water pollution has been expressed by the formation of an active task force on air and water criteria. This task force, which is sponsored by the Wisconsin Utilities Association, has been working with the Wisconsin State Department of Natural Resources to provide the Department with data on the problems of establishing adequate criteria for the control of air and water pollution. This task force has provided the Department with information on studies being conducted by a number of Wisconsin utilities. It is hoped that the results of these studies will provide the industry with knowledge that can be used to properly assess the degree and consequence of water and air pollution.

The problem of air pollution weighs heavily in the choosing of generation sites, the type of fuel used, the capital costs of equipment to maintain acceptable conditions, and ultimately on what the cost to the customer will be. The future will remain uncertain until air quality and emission standards are defined more clearly and equipment for reducing sulfur emissions is developed and becomes available commercially.

IV

COORDINATED PLANNING AND DEVELOPMENT

I. Structure of the Industry

Fifty-one interconnected systems currently generate approximately 95% of the energy consumed through electric utility service in the West Central Region. Table I below provides 1967 data as to number and size of these major utilities in the various ownership segments of the industry. This group generally can be described as consisting of those systems providing virtually all of the high voltage system facilities in this region.

Table I

Type of Ownership	Utilities	Non-Coincidental Peak Load (MW)	Gen Cap (MW)	Energy Prod (1000 MWH)
Investor-owned	25	22 954	26 032	118 566
Rural electric G&T cooperatives	19	1 657	1 382	5 646
State	6	1 461	1 120	4 226
Federal	1	746	2 048	9 692
	51	26 818	30 582	138 130

1967 load and capacity data for the individual major utilities in each ownership segment are shown in Appendix A.

In addition to these major utilities there are about 1000 other utility entities involved in generation and/or distribution of electric energy. These are identified as to type of ownership, size and general location in Appendix B.

II. Trends in the Development of Coordination Mechanisms

At present, nine coordinating organizations function within the region as follows:

Wisconsin Public Service Corporation-Wisconsin Power and Light Company-Madison Gas and Electric Company Pool
Wisconsin-Upper Michigan Systems
Illinois-Missouri Pool
Iowa Pool
Mid-America Interpool Network
Mid-Continent Area Power Planners
Missouri Basin Systems Group
Nebraska Public Power System
Upper Mississippi Valley Power Pool

Coordination areas of these organizations are shown in Figures 1-3. Appendix C presents first a brief summary and then detailed information on each body and its structure, purposes, and activities.

It is emphasized that there are no particular discontinuities in the pattern of interconnections at the boundaries of these organizations. Numerous other interconnection agreements and inter-relations exist that provide mechanisms for liaison and continuity in coordination across the region as demonstrated by the examples enumerated below:

1. MAIN and MAPP have overlapping membership with eight utilities being members of both of these organizations. This liaison arrangement is deemed particularly desirable for close coordination in planning and operation along the recently completed Twin Cities-Milwaukee-Chicago-St Louis-Twin Cities 345 kv loop. Operation of this loop and all other interconnecting transmission lines, and those otherwise mutually affected, is provided through established operating committees, through system simulation operating studies, and through continuous liaison between the respective coordination offices. The studies consist of current year operating studies, transfer capacity studies, and extreme disturbance studies. The areas of coordinated planning are handled through the planning arms of each of the organizations. Much of the planning is based upon

the aggregate load and capability forecasted and includes not only consideration of new facilities but also the future use of the interconnecting transmission facilities and power transactions to effect optimal use of generating equipment.

2. MAPP and MBSG liaison on projects of mutual interest is handled through the Intersystem Coordinating Committee. This committee was established by the respective organizations in 1965. Prior to the establishment of the MAPP Coordination Office and the associated Coordinating Committee, the Intersystem Committee organized an interim task force to review relay operating practices to assure that relaying of mutual interest would provide a reliable operation. Progress has been slow in the area of joint planning of transmission and generation and the committee itself has recently proposed that its parent organizations reconsider its membership and better define its responsibilities in the interest of improving progress.

3. All members of the Iowa Pool and UMVPP belong to the MAPP organization and have thereby broadened their capabilities in the traditional pooling activities of coordinated planning of generation and transmission, including power transactions, and coordinated operation of generation and transmission including short and long term maintenance scheduling, economy energy interchange, voltage profiles, automatic under-frequency load shedding, and dispatching procedures. This broadening comes about through the overview afforded in considerations of the Planning Committee which is geographic in its representation and through participation in the Coordinating Committee associated with the Coordination Office.

4. All members of the Wisconsin Power Group and Illinois-Missouri Pool belong to the MAIN organization.

5. MAPP-MAIN-UMVPP-Iowa Pool liaison, together with USBR participation in the MAPP Coordination Center, has resulted in development of an extensive teletype communication system permitting broad area coordination on day to day operating matters.

The area is presently served by three teletype

systems, all of which employ rented telephone company facilities. Cost sharing varies in each of the three systems ranging from equal shares to formulas using both number and size of systems involved. Teletype stations are located in the dispatching offices of the participating systems and the coordination centers. Use is limited to exchange of operating information and weather information.

The present systems are:

MAIN	15 terminals - 5 in Wisconsin, 4 in Illinois - 2 in Minnesota (MAPP & NSP), 2 in Missouri (UE & AEC), 1 in Little Rock, Arkansas (SCEC) 1 in Canton, Ohio (AEP ECAR)
UMVPP	10 terminals - 1 in North Dakota, 1 in South Dakota, 6 in Minnesota, 1 in Wisconsin, 1 in Iowa
USBR	1 in South Dakota
IOWA POOL	10 terminals - 2 in Minnesota (MAPP & NSP), 7 in Iowa, 1 in St Louis, Missouri (UE)

The UMVPP and Iowa Pool systems will be replaced in April 1969 by one MAPP system containing 25 terminals. This will include the present terminals plus new terminals for other MAPP members and adjacent utilities. The system will be comprised of 2 terminals in North Dakota, 6 terminals in Minnesota, 2 in Wisconsin, 2 in South Dakota (including USBR), 8 in Iowa, 2 in Nebraska (OPPD and CPPD), and 3 in Missouri (UE, St Joseph L&P and KCP&L). The MAPP system will utilize 100 wpm teletypes under the control of an automatic polling device located in the MAPP Center. All transmission will be by punched tape except during emergencies when an emergency override will permit manual transmission. Cost sharing will be according to a formula intended to recognize size of systems, mileage between adjacent terminals, and benefits accruing equally regardless of size.

6. As planning of specific facilities reaches a point in progress where the coordinating organization is agreed on the basic function and design, the participating utilities are represented on a number of task forces having responsibility for design, contractual arrangements, and use. The task force membership straddles organizational lines and provides further opportunities for coordination of associated facilities.

III. Projections of Future Coordinating Requirements

The following discussion of possible future organizational arrangements among electric utilities is in reference to the fifty-one systems identified in Section I as providing 95% of the electric service in the region. It is, of course, recognized that corporate consolidations will very likely reduce the number of separate entities in the future. However, there is no basis for predicting the specific patterns or timing such consolidations may follow other than a general reference to those already announced to be under study.

By 1970, MAPP intends to increase the coordination among the various parts of the MAPP organization, including the Iowa Pool, the UMVPP, and its Nebraska members by developing a super-pool agreement. This consolidation will result in these five sub-regional systems remaining as workable coordinating entities within the West Central Region:

Commonwealth Edison Company
Eastern Wisconsin Utilities (including the Upper Peninsula)
Illinois-Missouri Pool (including Central Illinois Light Company)
Mid-Continent Area Power Planners
Missouri Basin Systems Group

Each of these systems will exercise primary responsibility for planning and operation within their area, particularly with respect to economic matters.

With regard to reliability-oriented coordination, MAIN would continue with its present inter-pool operation in the eastern part of the region. Reliability-oriented coordination for the western portion of the region is expected to be provided by the recently executed Mid-Continent Area Reliability Coordination Agreement either expanded to include MBSG members

or through liaison arrangements with a separate MBSG reliability group.

Future patterns of generation and transmission developments prepared by the WCRAC contemplate 765 kv and 500 kv transmission lines across the region in the 1980's. These lines will provide capacity for meaningful power exchanges on a region-wide basis and also increase the interdependency among systems, particularly with respect to reliability. It is therefore proposed that a single West Central Reliability organization be established by 1980. In view of the large number of systems involved, manageability considerations dictate an interpool-type organization such as MAIN with the five above-identified area systems as members.

The foregoing material relating to future coordination patterns has been presented at meetings of the MAIN, MAPP and MBSG organizations in an effort to solicit views of utilities not represented on the WCRAC.

IV. Problems and Solutions

Operation of an electric power system is a complex matter involving the consideration of innumerable electrical elements and many people. Taken as a whole, the configuration changes from season to season, from day to day, and from hour to hour. To operate all of the interconnected electrical systems within a region in a truly coordinated manner becomes a tremendously complex matter requiring knowledgeable people, the necessary equipment and communications for the required overview, and of equal importance a strong desire on the part of all of those so engaged. That this coordination can be accomplished, and must be accomplished, is fully appreciated and has been taken on as a challenge of considerable substance by the utilities in this region.

It is recognized that the true strength of the operation is in the local knowledge of each area's needs and the resources available to supply these needs. The requirement then is for a coordinating effort which will supply the involvement necessary to do the job but which will not unnecessarily interfere in operations that can be adequately handled locally. Furthermore, it cannot be expected that a coordinating effort can be arbitrarily overlaid on the existing operation. Instead a coordination evolution is required which will gradually develop the capability of the coordinating organization and, in turn, the confidence of the participating systems with a resultant

growing willingness to accept the decisions and judgement of the coordinating personnel and to encourage their efforts.

Within the West Central Region there are variations in the nature of systems and load densities across the region producing differences in coordination problems and requirements. For example, a relatively few systems along the eastern edge of the region (Eastern Wisconsin Utilities, Commonwealth Edison, and the Ill-Mo Pool) generate almost 60% of the region's requirements while serving 15% of its area. As a result, pooling and interconnection arrangements appropriate for this area are markedly different than those applicable to the large number of systems serving the remainder of the region. Many types of utilities are represented with varying characteristics including that of size and of financing within the major groupings. Because of the hour-to-hour vital need to have a reliable operation, the coordinated operation of these systems has proven to be an endeavor not significantly affected by this dissimilarity. In the area of planning, substantial strides have been made in coordinating planning of both generation and transmission. As previously noted, only MAPP and MBSG have yet to fully coordinate their efforts. This situation is recognized by both organizations and is under active consideration.

V. Interregional Coordination

There are two formal arrangements for interregional coordination identified as such. These are the liaison arrangement between MAIN and ECAR, and MAIN and MAPP membership in the National Electric Reliability Council. Beyond these there are numerous bilateral interconnection agreements and other established channels for coordinated planning and operation with electric systems in adjacent regions.

The USBR has membership in both the Western Systems Coordination Council (WSCC) and the MAPP Coordination Committee and MAPP operating representatives attend WSCC operating meetings. These arrangements, along with these inherent within the USBR, provide liaison with the west lying region.

Some multi-system coordination activities involving other regions are: The MIIO Agreement among Commonwealth Edison and five major utilities in Indiana and Michigan, which, among other returns, resulted in system performance studies in depth which included Commonwealth Edison Company as a participant and enveloped the eastern portion of this region.

The Twin Cities-Kansas City 345 kv Coordinating Agreement - among four MAPP members and Kansas City Power and Light Company and St Joseph Light and Power Company in the South Central Region, which provides for the exchange of power and energy with the aim of optimizing the utilization of generation and bettering reliability. And the East-West Tie Closure Task Force, which was formed for the express purpose of studying the feasibility of and the procedures for closing the Bureau of Reclamation ties between the eastern and western portions of its Missouri River Basin system, and hence interconnecting the western region systems to the remainder of the U.S. interconnected systems.

The Manitoba Hydro Electric Board, although not yet interconnected with United States systems, participates in planning activities through its membership in the MAPP organization. As a result, negotiations for the 1970 construction of a Winnipeg-Grand Forks 230 kv interconnection have now been completed and construction and operating contracts signed. This interconnection will have a capacity of about 200 mw although it is being initially regarded as having a nominal 100 mw capacity for purpose of scheduling power and energy. This interconnection will provide Manitoba Hydro with interconnected operation with the U.S. systems, will make unnecessary the construction of thermal capacity, will provide a market for future excess power and energy, and will provide a source of energy during dry years. For the U.S., a power supply will be provided which is diversified in the source of the power and has prompt availability. The seasonal load diversity will permit mutually advantageous seasonal power exchanges and the reliability on either side of the boundary will be improved from the improved diversity overall. No unusual problems have been encountered in its planning even though the facility is being installed by such diverse interests as two investor-owned utilities and one G & T cooperative on the U.S. side, and by a Canadian Crown Corporation on the Canada side. Feasibility studies for a second 230 kv interconnection between Manitoba and the Garrison, North Dakota area are scheduled to be undertaken jointly by Manitoba Hydro and a number of MAPP and MBSG members.

Chicago, Illinois 60604

Gentlemen:

Referring to your inquiry addressed to the Little Dog Coal Company, in regard to the merger of the United Electric Coal Company and the Freeman Coal Mining Corporation, I desire to advise the following.

The Little Dog Coal Company ceased business on November 30, 1967. An application for an 11b Receivership is before the United States District Court for the Southern District of Illinois at Springfield, Illinois. The number of the case is S-Bk-68-973.

At the present time the Little Dog Coal Company has no employees whatsoever and it is impossible for us to look up the detailed evidence that you request.

As an officer of the defunct corporation, I can advise you that the Little Dog Mine is located at Gillespie, Illinois, in the center of the Illinois Terminal Railroad. The output of the mine was marketed mainly locally along that line and by truck. As far as I know none of the coal from this mine came into direct competition with the United Electric Coal Company at any point during its entire history.

Very truly yours,

LITTLE DOG COAL COMPANY

C. V. Beck,
President

SPECIAL AND SUPPPLEMENTAL PROVISIONS

SPECIAL REQUIREMENTS

Where an agency required, under Scope of Contract Provision, to use the Contracts listed herein finds that the specific articles or services contracted for will not meet a special requirement, articles or services having the same general characteristics needed to meet the special requirement may be procured: Provided, that a prior written waiver of the requirement for using this schedule is obtained from the General Services Administration. Request for such waivers shall be submitted to the Commissioner, Federal Supply Service, General Services Administration, Washington D. C. 20405, in accordance with Section 101-26.401-3 of the Federal Property Management Regulation and any implementing regulations of the requesting agency.

QUOTATIONS: (a) As used in this schedule the term "F. O. B. Mine (cars)" means free on board cars at the mine or at a water front dock. When the price quoted is F. O. B. Mine (cars) at dock, the bidder shall so indicate by inserting a small (d) in parenthesis after the unit price. A price quoted F. O. B. Mine (cars) without explanation or qualification shall mean free on board cars at the mine. (b) Whether or not this schedule shows that bids on any item are invited on the basis of F. O. B. cars destination or delivered-into-bins at destination the bidder may submit such bids, indicating in the item the basis thereof. In connection with a delivered-into-bin destination quotation, the bidder shall state the truck loading point.

Awards will be made on either an F. O. B. mine bid price (shipment to be made on Government Bills of Lading, or on commercial documents to be converted to Govern-

ment Bills of Lading at the destination) or delivered and stored bid price, except as otherwise indicated in the Schedule, unless the bidder indicates in the bid that delivery at the mine will be unacceptable. *F. O. B. mine price must be stated on all bids even though a bid is submitted on a delivered and stored basis.* If an award F. O. B. mine is not acceptable, a separate notation to this effect should be made on the bidding form, and the F. O. B. mine price inserted in proper space. The truck loading point must be specified in the bids based upon truck delivery. Only one price for entire tentative shipping schedule on each item will be considered. Bids offering separate prices for individual shipping periods under an item will not be considered for award.

The Government reserves the right to reject the bid of a bidder who has previously failed to perform properly or complete on time contracts of a similar nature, or a bid of a bidder who is not in a position to perform the contract.

BUREAU OF MINES ANALYTICAL RECORDS: (a) No bid will be considered on coal offered from mines on which the Bureau of Mines does not have analytical records, (b) Whenever the bidder's guaranteed analysis of coal offered or the latest Bureau of Mines analysis of the coal offered shows the offered coal not to be in conformance with the specifications set forth in this Invitation, the bidders offer shall be rejected as being non-responsive.

BITUMINOUS COAL AND LIGNITE DISTRIBUTION

CALENDAR YEAR 1967

Prepared March 27, 1968, by Joseph J. Gallagher, Division of Mineral Studies - Mineral Resource Evaluation, 202-343,4869.

Gallagher Depo Ex #3
12-12-18

BITUMINOUS COAL AND LIGNITE DISTRIBUTION
CALENDAR YEAR 1967

This report shows the distribution of bituminous coal and lignite in the United States during the calendar year of 1967 from coal producing districts of origin to geographic divisions and States of destination, broken down by methods of transportation and types of consumer use, and a comparative summary of total distribution during the calendar years of 1967 and 1966 by geographic divisions and States of destination, methods of transportation, and types of consumer use. This information provides individuals in the industry, the coal industry as a whole, the Government, and others with a better understanding of the participation of bituminous coal and lignite in the various energy markets of the Nation, both locally and nationally. The detailed data provide a benchmark for special studies and analyses of many of the factors that influence coal production and its utilization in the highly competitive energy market.

The data shown herein are based on reports submitted to the Bureau of Mines voluntarily by producers, sales agents, distributors, wholesalers and Great Lakes and tidewater commercial dock operators who normally produce or sell 100,000 tons or more annually. The Bureau sincerely appreciates the splendid cooperation of the producers and shippers in filing their individual reports, without which this report would not have been possible.

A separate report was requested for each coal producing district in which a company operated mines or from which it marketed coal. The coal producing districts are the districts recognized by the bituminous coal and lignite mining industries and are defined on page 3 of this report.

The producing and selling companies covered in the surveys accounted for about 94 percent of all coal produced during the periods covered. The report includes tonnages of coal which the companies covered in the surveys purchased for resale and marketed for smaller producing companies. All reports were edited carefully and verified against data from all other available sources. In order to account for total industry shipments during the periods, estimates for the remaining 6 percent of total shipments are included, based on data from coal trade and other reliable coal statistical reporting agencies.

Shipments from some of the coal producing districts differ slightly from the estimated net district production tonnages reported elsewhere by the Bureau of Mines for the reason that the coal distribution data, in some cases, include raw coal which is cleaned at the points of consumption whereas "production" reports pertain to estimates of clean coal only. Also, the distribution information includes some tonnages from small mines with annual output of less than 1,000 tons, the tonnages of which are marketed by and included as part of the shipments of larger producing and selling companies. The Bureau excludes from its standard production figures mines producing less than 1,000 tons per year.

Because of the detailed breakdown of the distribution statistics, certain figures cannot be shown separately without disclosing some of the data of companies that indicated on their report forms that their data may not be revealed. In most of such cases combinations have been made within each producing district of various "consumer uses," and "methods of movement". These combinations are indicated by brackets or explained in detail in the footnotes. In order to avoid distorting many tonnage data items that otherwise can be revealed and at the same time to keep the number of data items combined or footnoted to the irreducible minimum, the distribution report contains in the detailed "State of Destination" portion a section devoted to the summary of the smaller tonnage items not revealable, broken down by district of origin, method of movement, and consumer use, under the caption "Destinations not revealable". On the national basis the tonnages contained in "Destinations not revealable" in the calendar year of 1967 amount to 994,000 tons or only 0.2 percent of the grand total shipments during the period. The individual district totals range from no tonnages for some districts to a high of 0.9 percent of the district total in District 11. Also, District 6 (West Virginia Panhandle) has been combined with District 5 (Northern West Virginia) and District 22 (Montana) has been combined with District 23 (Washington) to conceal individual company data.

The data are arranged in Table I to show shipments of bituminous coal and lignite during the calendar year of 1967 from each producing district to each State of destination for each consumer use therein (except railroad fuel) by all methods of movement, and, where possible, by (1) all-rail; (2) river and ex-river; (3) Great Lakes; (4) tidewater; (5) truck; and (6) tramway, conveyor, and private railroad. Following the data that are available by States of destination, consumer use, and method of movement, tonnages are shown for items for which destination and/or consumer use are not available. These items are: (1) shipments to Canadian Great Lakes commercial docks; (2) vessel fuel; (3) shipments to U.S. Great Lakes dock storage; (4) overseas exports; (5) bunker fuel; (6) shipments to U.S. tidewater dock storage; (7) railroad fuel; (8) coal used at mines and sales to employees; and (9) net change in inventory. Table II is a comparative summary of distribution of bituminous coal and lignite produced in the United States during the calendar years 1967 and 1966 by geographic division and States of destination, methods of movement, and consumer use.

Respondents were asked to use railroad weights. If the company's records did not show the exact figures, they were asked to estimate the distribution detail required.

1417

All tonnage figures contained herein are in thousand net tons of 2,000 pounds.

The definitions of consumer uses as used in this report follow:

"Electric utilities". All privately owned electric utility companies and all publicly owned agencies engaged in the production and/or distribution of electric light and power. Publicly owned agencies include the following: Municipal electric utilities; Federal projects; rural electrification cooperatives, power districts, and State power projects; and "non-central stations". "Non-central stations" are those which operate to supply electric power primarily for such functions as public street lighting, water pumping, and sewage disposal.

"Coke and gas plants". Bituminous coal that is carbonized for the manufacture of coke, coal chemical materials, and gas at slot and beehive ovens, low- and medium-temperature carbonization operations, and in water gas and other coal gasification processes. This does not include coal used for non-carbonizing purposes such as space heating, foundry use, etc.

"Retail dealers". Any person (including the retail outlet, branch, or department of one who is also a producer, wholesaler, or dock operator), to the extent that he acts in the capacity of a supplier, shipper, or seller of bituminous coal and lignite in any transaction involving a shipment, sale, or sale and delivery to a consumer of broken-bulk bituminous coal and lignite physically handled in a truck, wagon, or other less-than-carload facility, without regard to type of consumer or to the quantity or frequency of delivery. Also, all railroad carload shipments that are delivered to a retail dealer's facilities are to be reported in this category (not including, however, carload shipments that are shipped for his account but not to his plant or facilities).

"All others". All consumers of bituminous coal and lignite other than electric utilities, coke and gas plants as defined above, retail dealers, railroads, coal mines, and mine employees.

"Railroad fuel". All coal shipped to railroad companies for engine, powerhouse, station, and all other uses. Includes coal furnished to locomotive tenders at the mine tipples.

"Vessel fuel". Coal used by vessels, tugs, ferry-boats, or other steam water craft on the Great Lakes.

"Bunker fuel". Coal used by ocean steamers, tugs, ferry-boats, or other steam water craft on tidewater.

"Coal used at mines and sales to employees." Includes coal used at mines for power and heat, coal made into beehive coke at mines, and coal used by mine employees.

Instructions to reporting companies on the reporting of "method of movement" included several distinctions that should be borne in mind by the users of this report. Shipments to United States and Canadian railroads for railroad fuel use are excluded from each specific method of movement. Respondents were requested to report total sales to railroads as railroad fuel, separated only as between United States railroad companies and Canadian railroad companies. All-rail shipments include coal loaded into railroad cars at the mines and hauled to ultimate destination via only rail movement, plus coal hauled by truck to a railroad-siding dumping facility and thence shipped to ultimate destination by rail. River shipments include coal loaded directly into river barges at the mine and coal hauled to river dumping facilities via rail, truck, or other means of transport and thence shipped to ultimate destination via river to customers receiving the coal alongside the river. Ex-river movement includes coal loaded directly into river barges at the mine and coal hauled to river dumping facilities via rail, truck, or other means of transport and thence shipped via river to a river lifting facility from which the coal was transshipped inland to the ultimate consumer or retail dealer located away from the river lifting facility. Great Lakes movement includes coal moving to the dumping piers on Lakes Erie, Ontario, and Michigan for further shipment via the Lakes or for use as vessel fuel. Tidewater movement includes coal shipped to tidewater dumping piers for loading into vessels as cargo or for use as bunker fuel. Respondents were requested to report as truck movement those shipments destined to the ultimate consumer via truck only.

The reporting companies were asked to report "shipments to distributors and wholesalers" only when the final State of destination and/or consumer use on such shipments were not known to the reporting company. Tonnages reported by producers as marketed through these channels were identified by name and address of the distributor or wholesaler, to enable the Bureau to trace the coal to the ultimate State of destination and consumer use.

Users of the distribution data contained herein should bear in mind that these data represent shipments "from" the producing fields and not necessarily consumption or receipts "by" consuming groups or States during the period. "Shipments to" or through certain marketing channels, such as to retail dealers and to storage facilities at Great Lakes and tidewater commercial docks, in some periods may exceed "deliveries from" dealers or facilities to ultimate consumers (primarily because of seasonal factors and coal in transit), while in other periods deliveries from retail dealers and storage facilities may exceed mine shipments to these marketing channels.

Comparable distribution data for the calendar years 1958 through 1966 are available in Bureau of Mines reports, copies of which may be obtained by writing to Chief, Section of Publication Distribution, Bureau of Mines, 4800 Forbes Avenue, Pittsburgh, Pa. 15213.

1418

Definition of Bituminous Coal and Lignite Producing Districts

DISTRICT 1—EASTERN PENNSYLVANIA

Pennsylvania.
Armstrong County (part)—All mines west of Allegheny River, in those areas served by the Pittsburgh & Shawmut Railroad and on the west bank of the River.
Fayette County (part)—All mines located on and east of the Youghiogheny River Valley branch of the Baltimore & Ohio Railroad.
Indiana County (part)—All mines not served by the Pittsburgh branch of the Pennsylvania Railroad.
Westmoreland County (part)—All mines served by the Pittsburgh branch of the Pennsylvania Railroad.
All mines in the following counties:

Bedford	Centre	Elk	Mifflin
Blair	Clearfield	Huntingdon	Somerset
Cambria	Clinton	McKean	Union
Cameron	Elk	Mifflin	Venango

Maryland—All mines in the State.
West Virginia—All mines in the following counties:

Grant	Mineral

DISTRICT 2—WESTERN PENNSYLVANIA

Pennsylvania.
Armstrong County (part)—All mines west of the Allegheny River, in those areas served by the Pittsburgh & Shawmut Railroad and on the east bank of the River.
Fayette County (part)—All mines except those on and east of the Youghiogheny River Valley branch of the Baltimore & Ohio Railroad.
Indiana County (part)—All mines served by the Pittsburgh branch of the Pennsylvania Railroad.
Westmoreland County (part)—All mines except those served by the Pittsburgh branch of the Pennsylvania Railroad.
All mines in the following counties:

Allegheny	Butler	Greene	Washington
Beaver	Fayette	Lawrence	

DISTRICT 3—NORTHERN WEST VIRGINIA

West Virginia.
Barbour County (part)—All mines served by or north of the Monongah & Glen Falls Railroad.
All mines in the following counties:

Barbour	Harrison	Monongalia	Taylor
Doddridge	Lewis	Preston	Tucker
Gilmer	Marion	Randolph	Upshur
Hampshire	Marshall	Ritchie	Wetzel

DISTRICT 4—OHIO—All mines in the State.
DISTRICT 5—MICHIGAN—All mines in the State.
DISTRICT 6—PANHANDLE
West Virginia—All mines in the following counties:

Brooke	Hancock	Marshall	Ohio

DISTRICT 7—SOUTHERN NO. 1

West Virginia.
Fayette County (part)—All mines west of the Gauley River, except those served by the Gauley River Railroad, and all mines served by the Chesapeake & Ohio Railroad and mines served by the Kanawha & Hocking.
McDowell County (part)—All mines in that portion of the county served by the Bay Port branch of the Norfolk & Western Railroad and south thereof.
Raleigh County (part)—All mines served along or to the east of the Chesapeake & Ohio Railroad and south thereof.
Wyoming County (part)—All mines in that portion of the county served by the Bay Port branch of the Norfolk & Western Railroad and south thereof.
All mines in the following counties:

Boone	Kanawha	Nicholas	Summers
Braxton	Lincoln	Putnam	Webster
Clay	Logan	Roane	
Fayette	Mercer	Summers	

DISTRICT 8—SOUTHERN NO. 2

West Virginia.
Fayette County (part)—All mines west of the Gauley River, except those served by the Gauley River Railroad.
McDowell County (part)—All mines west of and served by the Bay Port branch of the Norfolk & Western Railroad.
Mingo County (part)—All mines in that part of the county south of and served by the Chesapeake & Ohio Railroad.
Raleigh County (part)—All mines in the Coal River district, and served by the Coal River branch of the Chesapeake & Ohio Railroad and south thereof.
Wyoming County (part)—All mines in that portion of the county served by the Clarkson branch of the Virginian Railway and the mines of the Pond Fork Railroad.
All mines in the following counties:

Boone	Kanawha	Nicholas	Wayne
Braxton	Lincoln	Putnam	
Clay	Logan	Roane	
Fayette	Mercer	Summers	

Virginia.
Buchanan County (part)—All mines in the county east of the Pocahontas-Deepwater branch of the Norfolk & Western Railroad and north of Levis Creek in tributary of the Levisa Fork and in that portion served by the Pocahontas-Ridge branch of the Norfolk & Western Railroad.
Tazewell County (part)—All mines in the county except in Clear Fork and Laurel Creek districts and in that portion served by the Bay Port branch of the Norfolk & Western Railroad and south of Maitland and Bluefield on the Bluefield & Pocahontas Railroad.
All mines in the following counties:

Dickenson	Wise

Kentucky—All mines in the following counties in southern Kentucky:

Bell	Harlan	Leslie	Pike
Breathitt	Jackson	Letcher	Pulaski
Clay	Johnson	Lincoln	Rockcastle
Floyd	Knott	Magoffin	Whitley
Harlan	Knox	Martin	

Tennessee—All mines in the following counties:

Anderson	Claiborne	Fentress	Scott
Campbell	Cumberland	Morgan	

North Carolina—All mines in the State.

DISTRICT 9—WEST KENTUCKY

Kentucky—All mines in the following counties in western Kentucky:

Butler	Hopkins	Muhlenberg	Union
Christian	Logan	Ohio	Webster
Daviess	McLean	Todd	
Henderson	Marshall	Trigg	

DISTRICT 10—ILLINOIS—All mines in the State.
DISTRICT 11—INDIANA—All mines in the State.
DISTRICT 12—IOWA—All mines in the State.
DISTRICT 13—SOUTHEASTERN
Alabama—All mines in the State.
Georgia—All mines in the following counties:

Dade	Walker

Tennessee—All mines in the following counties:

Bledsoe	Grundy	Rhea	Van Buren
Franklin	Marion	Sequatchie	Warren

DISTRICT 14—ARKANSAS-OKLAHOMA
Arkansas—All mines in the State.
Oklahoma—All mines in the following counties:

Haskell	Le Flore

DISTRICT 15—SOUTHWESTERN
Kansas—All mines in the State.
Missouri—All mines in the State.
Oklahoma—All mines in the following counties:

Coal	Latimer	Pittsburg	Wagoner
Craig	Mayes	Pushmataha	

DISTRICT 16—NORTHERN COLORADO
All mines in the following counties in the State:

Adams	Gilpin	Jefferson	Weld
Boulder	Grand	Larimer	
Clear Creek	Jackson	Park	

DISTRICT 17—SOUTHERN COLORADO
Colorado—All mines except those included in District 16.
New Mexico—All mines except those included in District 18.

DISTRICT 18—NEW MEXICO
New Mexico—All mines in the following counties:

Colfax	McKinley	Rio Arriba	Sandoval
Mora	Rio Arriba	Sandoval	Taos
Quay			

Arizona—All mines in the State.
California—All mines in the State.

DISTRICT 19—WYOMING
Wyoming—All mines in the State.
Idaho—All mines in the State.

DISTRICT 20—UTAH—All mines in the State.
DISTRICT 21—NORTH DAKOTA-SOUTH DAKOTA—All mines in North Dakota and South Dakota.
DISTRICT 22—MONTANA—All mines in the State.
DISTRICT 23—WASHINGTON
Washington—All mines in the State.
Oregon—All mines in the State.
Alaska—All mines in the State.

TABLE I - DISTRIBUTION OF BITUMINOUS COAL AND LIGNITE PRODUCED IN THE UNITED STATES DURING THE CALENDAR YEAR OF 1967 BY DISTRICT OF ORIGIN, GEOGRAPHIC DIVISION AND STATE OF DESTINATION, METHOD OF MOVEMENT, AND CONSUMER USE.

(In Thousand Net Tons of 2,000 Pounds)

GEOGRAPHIC DIVISION STATE OF DESTINATION METHOD OF MOVEMENT CONSUMER USE	TOTAL	DISTRICT OF ORIGIN 1/								
		1	2	3 and 6	4	7	8	9	10	11
Shipments to all destinations in United States, Canada, and Mexico, by all methods of movement and consumer use, and overseas exports, total	558,647	43,696	40,890	54,470	45,690	40,973	149,318	47,788	66,083	19,006

FOOTNOTES (Where special combinations of consumer uses, methods of movement, States of destinations, etc., are shown in footnotes, it is for purposes of concealment of individual respondent figures)

1/ For definitions of bituminous coal and lignite producing districts, see page 3.
2/ Excludes shipments to Canadian Great Lakes commercial docks and United States dock storage for which consumer uses are not available; however, includes vessel fuel, the destinations of which are not available.
3/ Excludes overseas exports and United States tidewater dock storage for which consumer uses are not available; however, includes bunker fuel, the destinations of which are not available.
4/ Shipments via tramway, conveyor, and private railroad are included with truck shipments.
5/ Shipments via river and ex-river are included with all-rail shipments.
6/ Shipments via tidewater are included with all-rail shipments.
7/ Shipments via Great Lakes are included with all-rail shipments.

AIR POLLUTION BY FEDERAL FACILITIES

REPORT

OF THE

SECRETARY OF HEALTH, EDUCATION, AND WELFARE

TO THE

CONGRESS OF THE UNITED STATES

IN COMPLIANCE WITH

PUBLIC LAW 90-148

THE CLEAN AIR ACT, AS AMENDED

JANUARY 1968

APRIL 1, 1968.—Ordered to be printed

U.S. GOVERNMENT PRINTING OFFICE
92-098 WASHINGTON : 1968

SENATE RESOLUTION 261

Submitted by Mr. Randolph of West Virginia

IN THE SENATE OF THE UNITED STATES.

Agreed to April 1, 1968.

Resolved, That there be printed as a Senate document the report of the Secretary of Health, Education, and Welfare, entitled "Air Pollution by Federal Facilities", in compliance with the provisions of title I, section 111(b) of the Clean Air Act, Public Law 90-148, as amended; and that there be printed 2,500 additional copies of such document for the use of the Committee on Public Works.

Attest:

FRANCIS R. VALEO,
Secretary.

By DARRELL ST. CLAIRE,
Chief Clerk.

LETTER OF TRANSMITTAL

THE SECRETARY OF HEALTH, EDUCATION, AND WELFARE,
Washington, D.C., February 7, 1968.

Hon. HUBERT H. HUMPHREY,
President, U.S. Senate,
Washington, D.C.

DEAR MR. PRESIDENT: In accordance with the provisions of title I, section 111(b) of the Clean Air Act, Public Law 90-148, as amended, there is transmitted herewith a report on measures being taken to control the emission of air pollutants from Federal facilities.

Sincerely,

WILBUR J. COHEN,
Acting Secretary.

AIR POLLUTION BY FEDERAL FACILITIES

INTRODUCTION

The Clean Air Act, as amended, emphasizes the need for Federal leadership and assistance to State and local agencies in the control of air pollution. In addition, the act indicates that the Federal agencies shall cooperate with the Department of Health, Education, and Welfare and with any air pollution control agency in preventing and controlling air pollution from the facilities for which they are responsible. It also provides for the establishment of classes of air pollution sources for which limited permits could be issued and further requires the Secretary to submit an annual report to the Congress on the status of such permits and compliance therewith. The language of the act is such that the Secretary is given discretion with respect to the classification and permit procedure to be established.

In addition to the act mentioned above, the program of abatement and control of air pollution from Federal facilities is governed by Executive Order 11282, dated May 26, 1966, entitled "Control of Pollution Originating from Federal Installations," by the "Performance Standards and Techniques of Measurement" prescribed by the Secretary of Department of Health, Education, and Welfare, issued June 2, 1966, in response to "Sec. 5 Standards" of Executive Order 11282 and by Bureau of the Budget Circular No. A-78 issued on August 6, 1966, and sent to the heads of executive departments and establishments.

It is expected that several years effort will be required to fully control air pollutant emissions from Federal establishments in accordance with the best current practices. To provide the necessary technical guidance for this overall effort, the National Center for Air Pollution Control of this Department has established a Federal Facilities Section, the staff of which will devote full time to the surveillance of air pollution problems arising from Federal activities, the extension of technical assistance to other agencies and departments, and to studies of the scheduling of the necessary improvements in control of the emissions at Federal establishments.

ACCOMPLISHMENTS

The Performance Standards accompanying Executive Order 11282, through section 76.5(c)(1), called for the Secretary of the Department of Health, Education, and Welfare to establish by regulation limits on the emission of sulfur oxides to the atmosphere from Federal facilities within 6 months of the effective date of the standards for standard metropolitan statistical areas or standard consolidated areas which have a population exceeding 2 million and a population density exceeding 15,000 persons per square mile. The result of this require-

ment, which pertains only to the New York, Chicago, and Philadelphia metropolitan areas, was the preparation and publication in the November 22, 1966, issue of the Federal Register of a notice of intention to adopt—30 days after the publication of the notice—specific limits on the emission of sulfur oxides in these three areas. The 30-day effective time limit was extended by the Secretary of the Department of Health, Education, and Welfare for an additional 90 days at the request of an industrial trade association which was concerned about the impact of the proposed regulations on certain segments of the fossil fuel industry. The proposed limits were published in final form in the March 23, 1967, issue of the Federal Register to be effective October 1, 1968.

The limitations on sulfur oxide emissions for Federal facilities in these three heavily polluted areas are sufficiently stringent to cause serious concern and attention. Information received indicates that all agencies intend to comply with the regulations as rapidly as possible. This compliance is related closely to the efforts of the air pollution control agencies in these cities to relieve their population of excessively high exposure to sulfur oxides and is an excellent example of cooperation by Federal agencies with local authorities.

During 1967, a number of studies of special Federal problems of air pollution and its control have been undertaken. Both the General Services Administration and the Department of Defense began studies of problems associated with fuel supply nationally and with specific emphasis on New York, Philadelphia, and Chicago. The Department of Defense initiated a program of testing fuel oil for its sulfur content since the current military and Federal specifications on fuel oil permit sulfur contents which are considerably in excess of that associated with current and anticipated limits. Several directives were issued to military commands to put this new program into effect immediately. Laboratory resources of the Department of Defense will be utilized for this program.

Toxic rocket propellants continued to be a problem during 1967. Potential beryllium emissions have been controlled, largely because of the Public Health Service policy statement on beryllium issued in 1966, and through the excellent cooperation by the two principal agencies concerned (DOD and National Aeronautics and Space Administration).

Interagency leadership resulted in preventing potential widespread atmospheric pollution with toxic chemicals under development for use in Federal missile and aerospace activities. Both the Department of Defense and the National Aeronautics and Space Administration took appropriate actions to insure compliance with recommended guidelines issued with the Public Health Service policy statement on beryllium.

The policy, based on recommendations of the National Academy of Science's Committee on Toxicology, maintains that, with present scientific information, prudence requires the assumption that all compounds of beryllium possess long-range toxicity for some humans. Therefore, no amount of beryllium should be deliberately emitted to the atmosphere, except under circumstances directly relevant to defense of the Nation.

New justification for the longstanding Federal concern about contamination of the ambient atmosphere, by even minute amounts of

beryllium arising from any activity of government, was provided by a recent court decision. In October 1967 a Pennsylvania jury awarded $109,120 to a 45-year-old mother on the ground that her serious lung disease was caused by beryllium fumes emitted to the atmosphere by an industrial plant located several miles from her residence. (*Heck v. Beryllium Corp.*, Berks County, Pennsylvania Court of Common Pleas.)

Although that court decision produced no change in the conservative Public Health Service policy toward control of beryllium, it did stimulate intensified activity within the Department of Defense to assure enforcement of the stringent guidelines issued earlier to control any rocket motor tests required by the national defense. It also stimulated serious reappraisal of the need for toxic rocket propellants, and this reappraisal was going on at year's end, when virtually all research and development involving beryllium as a propellant had stopped.

Activity also was continued in Chattanooga and Hamilton County, Tenn., because of continued interest of citizens of the area in general air pollution abatement, because of complaints concerning the emissions from the Volunteer Army Ammunition Plant in Hamilton County and because of technical problems involving efforts to control sulfur oxides, nitric oxides, sulfuric and nitric acid mists, red water incinerator wastes and other contaminants. The Abatement Program is studying the air pollution situation of the entire area and air pollution from the ammunition plant. The most significant recommendation made to the Office of the Surgeon General, Department of the Army, by the Public Health Service was to install catalytic reduction units at the plant to reduce markedly the emissions of nitric oxides to the atmosphere from the nitric acid plants at the Volunteer Army Ammunition Plant.

Special cooperation continues with the Tennessee Valley Authority through its Division of Health and Safety. In addition to participating in an advance review of TVA's phased and orderly plan prior to its submission to the Bureau of the Budget, the Federal Facilities Section and meteorological personnel of the abatement program also reviewed TVA's current plans to control air pollution from its new plant in Cumberland City, Tenn. This plant will burn a high-sulfur coal which is the most readily available fuel in the quantities needed and will have one or two 1,000 foot stacks equipped with highly efficient (99 percent) electrostatic precipitators to control particulate emissions, depending on final engineering design decisions. Although there is not considered to be a currently acceptable economic method of removing sulfur oxides from these stack gases. TVA recognizes that these oxides may be a problem and has provided for installation of control mechanisms in the future when they are developed. It should be noted here that considerable research is underway by the Public Health Service and TVA, by the Bureau of Mines of the Department of the Interior and by private utilities and chemical companies to develop technology to remove sulfur oxides from stack gases of powerplants.

Most of the activity by the Federal Facilities Section of the abatement program involved assistance to the departments and agencies in preparing their 5-year phased and orderly plan for the Bureau of

the Budget and, during the second half of 1967, in analysing these phased and orderly plans for the Bureau of the Budget. Fourteen departments and agencies prepared and submitted their plans for air pollution control improvements to the Bureau of the Budget by July 1, 1967; the Post Office Department plan was received December 26, 1967.

The agencies estimated a cost of approximately $18 million for air pollution abatement work scheduled for fiscal year 1968. In fiscal year 1969, the projects included in the approved plan are estimated to cost approximately $21 million.

The air pollution phased and orderly plan for the initial 14 departments and agencies submitting data to the Bureau of the Budget as called for by Executive Order 11282 covers proposed corrective actions for fiscal years 1969 through 1973 affecting approximately 435 projects.

The plan by agency breaks down as follows:

	Projects
Department of Defense	349
Veterans' Administration	26
Atomic Energy Commission	13
Tennessee Valley Authority	5
All other agencies	42
Total (all agencies)	435

The projects represent Federal facilities in 49 of the States, the District of Columbia and the Commonwealth of Puerto Rico. No projects were submitted from Delaware, the Virgin Islands, American Samoa or Guam. All of the projects are specifically concerned with abatement of air pollution. Some place in this plan are examples of all of the usual types of air pollution problems found among non-Federal activities across the country as well as unique problems associated with the production of munitions and hardware associated with our national defense. The details of these projects form the basis for a national inventory of Federal air pollution sources and needed corrective measures.

Projects were reported to the Bureau of the Budget on forms designed by that Bureau and these were reviewed by the Federal Facilities Section for the Bureau. In some cases, as necessary, further consultation was held with the departments or agencies concerned and minor amendments and corrections were made. In many cases, the cost estimates are based upon preliminary engineering and economic judgments and, before final decisions are made, may be modified to reflect new choices for corrective measures. For example, where lower sulfur fuels are necessary, final decisions concerning the use of coal, oil or natural gas will depend upon the economic picture at the time of purchase and upon the ready availability of an appropriate low-sulfur fuel at the site. Generally speaking, from an engineering and cost point of view, the plans presented acceptable proposals for abatement of air pollution and the Bureau of the Budget was so notified.

As might be expected, the agencies' proposals were directed principally at the reduction of sulfur oxide emissions, reduction of particulates by installation of high-efficiency separators and provision of improved methods of solid waste disposal through incineration or sanitary land-fill operations. Compliance with the strict sulfur oxide regulations governing facilities in New York, Philadelphia, and Chicago is receiving careful attention. Areas in the country where there

exists the actuality or probability of interstate air pollution also had high priority in these plans. Provision of flue gas scrubbers, smoke detectors, and alarms, submerged inlets for certain fuel storage units, installation of special incinerators for disposal of biological wastes, high-efficiency cyclones, absorption towers, mist eliminators, catalytic reduction units, waste shredders and wood hammer mills, are examples of other abatement devices needed for the projects.

At the request of the Bureau of the Budget, the Federal Facilities Section analyzed the 1969 portion of the 5-year phased and orderly plan and suggested to the Bureau a system of priorities through which the projects could be classified by financial quartiles. In establishing these priorities, consideration was given items such as complaints, violation of local air pollution codes, degree of seriousness of potential health hazard, location of the facility with special emphasis on interstate areas and interstate areas in which the Department of Health, Education, and Welfare had initiated formal abatement actions under the Clean Air Act of 1963, as amended. Attention also was called to projects on which abatement work has been started or scheduled in 1968 out of regularly appropriated funds of each agency.

The Federal Facilities Section, abatement program, was notified that the Bureau of the Budget approved for financing in 1969 all projects for facilities located in the New York City, Chicago, and Philadelphia metropolitan statistical areas, the Washington, D.C. metropolitan area, all projects where violation of local air pollution control regulations exist, where significant potential health hazards exist and all projects located in interstate areas where the Department of Health, Education, and Welfare has started air pollution abatement procedings under the Clean Air Act of 1963, as amended. A list of these projects received from the Bureau of the Budget, by agency and location, is found in appendix A.

The data submitted by the agencies in most cases included abatement projects on which work had been started or scheduled in 1968 fiscal year. Many of these projects are to be completed during that year but others require additional support in subsequent fiscal years. (A list of the projects scheduled to start in 1968 is found in app. B.) These corrective measures scheduled for 1968 cover 166 projects to be financed from regularly appropriated construction, operations, and repair or other moneys and represent a sizable contribution to air pollution control efforts by the Federal agencies. The projects scheduled for completion during 1968 for the most part solve relatively simple problems such as conversion to similar but lower sulfur fuels, installation of smoke detectors or provision of sanitary land-fills as a substitute for open burning of solid wastes. The Veterans' Administration and TVA are outstanding with respect to these planned projects as part of their regular operations, repair and maintenance activities. The Department of Defense also had an appreciable input.

Progress with respect to the abatement projects which are funded for fiscal year 1969 can be followed through the annual reports called for from each participating agency by Executive Order 11282 and Bureau of the Budget Circular No. A–78. The first of these reports is due on July 1, 1968 at the Bureau of the Budget.

Several agencies have problems of open burning of solid wastes which, although not reported in the phased and orderly plan, are

being studied by the agencies in cooperation with the Federal Facilities Section of the National center for Air Pollution Control and the solid wastes program of the National Center for Urban and Industrial Health of the Department of Health, Education, and Welfare. The results may indicate needs for further proposals for air pollution abatement as an extension of the plan in fiscal years 1969 or 1970.

The adoption of regulations for the control of organic solvents such as rule 66 of the Los Angeles County Air Pollution Control District and rule 3 of the San Francisco Bay Area Air Pollution Control District during 1967 also brings a need for several agencies to assess this problem as soon as possible. The Department of Defense already is active in this respect and all other agencies have been notified to review their operations in the Los Angeles and the San Francisco areas. There appears to be a need for uniformity with respect to these rules to prevent the adoption of different requirements in many different sections of the country. The National Center for Air Pollution Control currently is establishing an Advisory Committee on Organic Solvents to consider this matter further.

During December 1967, the Department of Health, Education, and Welfare called a conference under procedures of the Clean Air Act of 1963, as amended, to consider problems associated with interstate air pollution in the Washington, D.C., metropolitan area. As part of that conference each Federal agency presented its plans to abate air pollution from its facilities in the defined area. Federal installations account for about 30 percent of the air pollution of the District of Columbia and about 10 percent of the metropolitan area total. It is estimated that approximately $2 million will be required to abate air pollution from Federal operations in the area considered by the conference, exclusive of the $733,333 grant made by the Department of Health, Education, and Welfare to the government of the District of Columbia to permit the development of a sanitary landfill and the abolishment of open burning at the Kenilworth dump. Technology is available to solve the other major air pollution problems in the area. The General Services Administration is expected to play a key part in Washington, as elsewhere, because of its role in purchasing low-sulfur fuels for both the Federal Government buildings and those of the District of Columbia. The presentation of the Federal agency plans was important to this conference because of the relatively high density of Federal activities in the District of Columbia area.

No requests have been received from any department or agency for exemption from the provisions of the standards accompanying Executive Order 11282, and no requests have been received for operating permits. The cooperation by the Federal agencies with the Department of Health, Education, and Welfare and the Bureau of the Budget in developing the 5-year phased and orderly plan is overwhelming evidence of their desire to fully participate in developing national leadership in air pollution abatement envisioned by the Executive order. Eventual realization of this objective will depend upon the rate at which the program is funded.

APPENDIXES

APPENDIX A

1969 PROJECTS TO BE FUNDED (BASED UPON DATA RECEIVED FROM BOB DEC. 28, 1967)

Agency	Location	Problem
Department of Defense:		
Air Force	Andrews Air Force Base, Camp Springs, Md.	Fuel conversion, incinerator, smoke detectors.
	Davis-Monthan Air Force Base, Tucson, Ariz.	Smelting of scrap metal.
Army	Cameron Station, Alexandria, Va.	Vapor control, incinerator replacement.
	Volunteer Army Ammunition Plant, Chattanooga, Tenn.	NO_2, SO_2, H_2SO_4 particulates, incinerator.
	Arlington Hall Station, Arlington, Va.	Incinerators.
	Fort George Meade, Odenton, Md.	Fuel conversion, vapor control.
	Frankford Arsenal, Philadelphia, Pa.	Fuel conversion.
	Picatinny Arsenal, Dover, N.J.	Electrostatic precipitators, flue gas scrubbers, fuel conversion, incinerators.
	Fort Hamilton, Brooklyn, N.Y.	Vapor control, scrubbers, etc.
	Fort Dix, Fort Dix, N.J.	Mechanical collectors.
	Sunflower Army Ammunition Plant, Johnson Co., Kans.	Incinerators absorption tower, fly ash collectors.
	Joliet Army Ammunition Plant, Joliet, Ill.	Fuel conversion, mist eliminators, catalytic reduction, incinerators, particulate collectors.
	Pentagon, Washington, D.C.	Vapor control.
	Badger Army Ammunition Plant, Baraboo Wis.	Electrostatic precipitators, fuel conversion vapor control.
Navy	Naval Public Works Center, Great Lakes, Ill.	Fuel conversion.
	Naval Supply Depot, Philadelphia, Pa.	Do.
	Naval Damage Control Training Center, Philadelphia, Pa.	Firefighter school.
	Naval Training Center, Great Lakes, Ill.	Fuel conversion, fire training school.
	Naval Shipyard, Philadelphia, Pa.	Fuel conversion, incinerator, foundry fume collector.
	Electronic Training Center, Naval Station, San Diego, Calif.	Fire training school.
	Naval Air Station, Barber's Point, Honolulu, Hawaii.	Sanitary landfill, firefighter school.
	Naval Research Laboratory, Washington, D.C.	Smoke detectors.
	Naval Air Station, Glenview, Ill.	Firefighter school, smoke detectors.
	U.S. Naval Ordnance Lab, White Oak, Md.	Smoke detector.
	San Francisco Bay Naval Shipyard, Vallejo, Calif.	Fuel conversion.
	Naval Training Station, San Diego, Calif.	Firefighting school.
	Naval Air Station, Alameda, Calif.	Vapor recovery; firefighter school; scrubber; afterburner.
	Naval Air Station, Moffett Field, Sunnyvale, Calif.	Vapor control; sanitary landfill.
	Marine Corps Supply Center, San Bernardino, Calif.	Incinerator.
	Marine Corps Base, 29 Palms, San Bernardino, Calif.	Landfill.
	Naval Supply Center, Norfolk, Va.	Vapor control; fume collectors on smelters; rebuild furnaces.
	Naval Air Station, San Diego, Calif.	Fire school; vapor control, plating plant control.
	San Francisco Bay Naval Shipyard, San Francisco, Calif.	Fuel conversion.
	Naval Fuel Depot, San Pedro, Calif.	Vapor control.
	Naval Station, Long Beach, Calif.	Incinerator.
	Fleet Training Center, Newport, R.I.	Fire training center.
	Navy Public Works Center, Norfolk, Va.	Fuel conversion alarms and detectors.
	Navy Public Works Center, Newport, R.I.	Incinerator, fly ash eliminators.
	U.S. Naval Air Station, Minneapolis, Minn.	Vapor control; firefighter school; smoke detector.
	Naval Air Depot, Hawthorne, Nev.	Smoke recorders; fume collectors, fire school; baghouses.
	Marine Corps Station, San Diego, Calif.	Smoke detector.
	Naval Station, Kodiak, Alaska	Sanitary landfill; fire school; smoke detectors.

Agency	Location	Problem
Department of Defense—Con.		
Navy—Con.	Puget Sound Naval Shipyard, Bremerton, Wash.	Paint and metal fumes; smoke collectors; shredder and pulper.
	Naval Torpedo Station, Keyport, Wash.	Plating fumes; landfill; shredder-pulper.
	Naval Station, Adak, Alaska	Sanitary landfill, incinerator, fire school.
Corps of Engineers (Civil Works)	San Francisco Harbor	Drift removal.
	Potomac and Anacostia Rivers, Washington, D.C.	Do.
Department of Commerce	None	None.
Department of Justice	do	Do.
Department of Interior	do	Do.
General Services Administration	do	Do.
Treasury Department	do	Do.
Atomic Energy Commission	Brookhaven National Laboratory, Brookhaven, N.Y.	Fuel conversion.
	Argonne National Laboratories, Argonne, Ill.	Do.
	Bendix Plant, Kansas City, Mo.	Incinerator and waste destructor.
Department of Health, Education, and Welfare.	PHS Hospital, Detroit, Mich.	Incinerators and boilers.
	Gallaudet College, Washington, D.C.	Incinerators.
Department of Agriculture	Agricultural Research Center, Beltsville, Md.	
	Area No. 3, Animal husbandry, meat labs.	Fuel conversion, incinerator.
	Animal Parasite Station	Incinerator.
Smithsonian Institution	National Zoological Park, Washington, D.C.	Do.
Veterans' Administration	VA Hospital, East Orange, N.J.	Replace boilers.
	VA Hospital, San Fernando, Calif.	Incinerator, new and replacement.
National Aeronautics and Space Administration.	NASA Industrial Plant, Downey, Calif.	Incinerator for solvent control.
	Michoud Assembly Facility, New Orleans, La.	Incinerator.
	Mississippi Test Facility, Bay St. Louis, Miss.	Incinerator or sanitary landfill.
Post Office Department	Plan arrived late (Dec. 28, 1967), projects not reviewed by HCAPC.	
Tennessee Valley Authority	Shawnee Steam Plant, McCracken Co., Ky.	Installation of electrostatic precipitators.
	Gallatin Steam Plant, Gallatin, Tenn.	Electrostatic precipitators.
	Colbert Steam Plant	Electrostatic precipitators and mechanical collectors.
	Widows Creek Steam Plant	Do.
	Power Building, Chattanooga, Tenn.	Install dust collector or change fuel.

APPENDIX B

1968 PROJECTS SUBMITTED BY PARTICIPATING DEPARTMENTS AND AGENCIES

Agency	Location	Problem
Department of Defense:		
Air Force	Williams Air Force Base, Chandler, Ariz.	Vapor control.
	Beale Air Force Base, Marysville, Calif.	Scrubber for incinerator.
	Cape Kennedy, Cape Canaveral, Fla.	Incinerator modifications, firefighting school.
	Eglin Air Force Base, Walton Beach, Fla.	Install incinerator; vapor control; catalytic combustion chamber.
	Patrick Air Force Base, Cocoa Beach, Fla.	Provide incinerator.
	Robins Air Force Base, Warner Robins, Ga.	Incinerator and furnace installation.
	Scott Air Force Base, Belleville, Ill.	Sanitary landfill, modify heating plant.
	Chanute Air Force Base, Rantoul, Ill.	Install 2 incinerators.
	Bunker Hill Air Force Base, Peru, Ind.	Install incinerator, electrostatic precipitators.
	Phelps Collins ANG Base, Alpena County, Mich.	Vapor control.
	Offutt Air Force Base, Omaha, Nebr.	Modify incinerator, new incinerator.
	Omaha Air Force Station, Omaha, Nebr.	Fuel conversion.
	Lockport Air Force Station, Lockport, N.Y.	Mechanical filters.
	Hill Air Force Base, Ogden, Utah	Fuel conversion, modify incinerator, wood hammer mill.
	F. E. Warren Air Force Base, Cheyenne, Wyo.	Fuel conversion or electrostatic precipitators.
	Wright-Patterson Air Force Base, Greene County, Ohio.	New incinerator with new control equipment.
	Selfridge Air Force Base, Mount Clemens, Mich.	New incinerator, modify heating plant.

Agency	Location	Problem
Department of Defense—Con.		
Air Force—Con.	Wurtsmith Air Force Base, Oscoda, Mich.	Electrostatic precipitators.
	Vandenberg Air Force Base, Santa Barbara County, Calif.	Installation of vapor recovery system.
	Tyndall Air Force Base, Panama City, Fla.	Landfill.
	Hickam Air Force Base, Honolulu, Hawaii.	Modify incinerators; install pressure and vacuum relief valves.
	Barksdale Air Force Base, Bossier City, La.	New incinerator and waste disintegrators.
	L. G. Hanscom Field, Bedford, Mass.	Install smoke detectors.
	McGuire Air Force Base, Burlington County, N.J.	Fuel conversion.
	Montauk Air Force Station, Montauk, N.Y.	Do.
	National Guard Air Base, Floyd Bennett Field, Kings County, N.Y.	Do.
	Minot Air Force Station, Minot, N. Dak.	Do.
	Greater Pittsburgh Airport, ARPT, Allegheny County, Pa.	Install fill extension pipes.
	Lackland Air Force Base, San Antonio, Tex.	Install shredder.
	Perrin Air Force Base, Sherman, Tex.	Install incinerator.
	St. Albans Air Force Station, St. Albans, Vt.	Electrostatic precipitators.
	Minneapolis-St. Paul International Airport, Minneapolis, Minn.	Fuel conversion.
	Blaine Air Force Station, Blaine, Wash.	Install dust collectors.
	Lockbourne Air Force Base, Columbus, Ohio.	Fuel conversion.
	Kingsley Field, Klamath Falls, Oreg.	Modify tank filling equipment.
Army	Fort Lewis, Tacoma, Wash.	Fuel conversion, vapor control, smoke detector.
	Fort Knox, Fort Knox, Ky.	Fuel conversion, high efficiency separators.
	Camp Pickett, Blackstone, Va.	Fuel conversion, vapor control.
	USAQM Center and Fort Lee, Fort Lee, Va.	Do.
	Volunteer Army Ammunition Plant, Chattanooga, Tenn.	Multiple emissions.
	Tobyhanna Army Depot, Tobyhanna, Pa.	Smoke detector, vapor control.
	Watervliet Arsenal, Watervliet, N.Y.	Modify incinerator, smoke detector, contract waste disposal.
	Fort Dix, Fort Dix, N.J.	Fuel conversion, mechanical collectors.
	Fort Leonard Wood, Waynesville, Mo.	Fuel conversion, vapor control.
	Cornhusker Army Ammunition Plant, Grand Island, Nebr.	New incinerator, fuel conversion.
	Fort Benjamin Harrison, Indianapolis, Ind.	Fuel conversion, smoke alarm.
	Sierra Army Depot, Herlong, Calif.	Fuel conversion.
	D. A. Rocky Mountain Arsenal, Denver, Colo.	Vapor control, incinerator control.
Navy	Navy Public Works Center, Great Lakes, Ill.	Fuel conversion.
	Naval Training Center, Great Lakes, Ill.	Fuel conversion, firefighter school.
	Naval Shipyard, Philadelphia, Pa.	Incinerator, fuel conversion, fume collector.
	Naval Supply Depot, Philadelphia, Pa.	Fuel conversion.
	Fleet Training Center, San Diego, Calif.	Firefighter school.
	Fleet Training Center, Newport, R.I.	Firefighter training school.
	Public Works Center, Newport, R.I.	Incinerator, flyash controls.
	Naval Shipyard, Boston, Mass.	Incinerator, dust collectors.
	Naval Air Station, Honolulu, Hawaii.	Sanitary landfill, firefighting school.
	Naval Shipyard, Charleston, S.C.	Dust collector, fume collector.
	Naval Training Center, Bainbridge, Md.	Precipitators and incinerators, scrubbers.
	Electrical Training Center, Norfolk, Va.	Firefighting school.
	Naval Air Station, Brooklyn, N.Y.	Fuel conversion.
	Naval Hospital, Queens County, N.Y.	Fuel conversion, scrubbers on incinerators.
	Marine Corps Supply Activity, Philadelphia, Pa.	Fuel conversion.
	Naval Hospital, Philadelphia, Pa.	Do.
	Naval Air Engineering Center, Philadelphia, Pa.	Do.
	Naval Air Development Center, Philadelphia, Pa.	Do.
	Naval Ammunition Depot, Monmouth County, N.J.	Do.
	Mitchell (Shaw Federal Housing (part of shipyard), Garden City, N.Y.	Do.
	Hq 1st Marine Corps District, New York, N.Y.	Do.
	Naval Reserve Training Center, Clifton, N.J.	Do.

Agency	Location	Problem
Department of Defense—Cont.		
Navy—Cont.	Naval Reserve Training Center, Elizabeth, N.J.	Fuel conversion.
	Naval Reserve Training Center, Nassau County, N.Y.	Do.
	Naval Reserve Training Center, Suffolk County, N.Y.	Do.
	Naval Reserve Training Center, Jersey City, N.J.	Do.
	U.S.N.R. Reserve Shipyard, Keyport, N.J.	Do.
	Naval Reserve Training Center, Watertown, N.Y.	Do.
	Naval and Marine Corps Training Center, Schuyler, N.Y.	Do.
	Naval Reserve Training Center, Youngstown, N.Y.	Do.
	Marine Corps Reserve Training Center, New York, N.Y.	Do.
	Naval Shipyard, Kings County, N.Y.	Install scrubber on incinerator.
U.S. Department of Agriculture	Hoxie	None.
Department of Interior	do	Do.
Smithsonian	do	Do.
Atomic Energy Commission	Argonne National Laboratory, Argonne, Ill.	Fuel conversion.
	Brookhaven National Laboratory, Brookhaven, N.Y.	Do.
	Mound Laboratory, Miamisburg, Ohio	Fuel conversion incinerator w/scrubber.
	Burlington Plant, Burlington, Iowa	Fuel conversion.
	Knolls Atomic Power Laboratory, West Milton, N.Y.	Install smoke detectors, fuel conversion.
	Knolls Atomic Power Laboratory, Niskayuna, N.Y.	Install submerged filling inlet.
	Oak Ridge National Laboratory, Oak Ridge, Tenn.	Install vapor recovery and control systems.
	Argonne National Laboratory, Bingham County, Idaho.	Install alarm systems.
	Savannah River Plant, Aiken and Barnwell Counties, S.C.	Sanitary landfill.
	Richland Operations Office Adams, Benton, Grant, and Franklin Counties, Wash.	Install monitoring and recording instruments.
	Knolls Atomic Power Laboratory, Bingham County, Idaho.	Install smoke detector, increase stack height, install fuel air controls.
Corps of Engineers (Civil Works)	Puget Sound	Drift removal.
	New York Harbor	Do.
	Derrickboat Tonawanda, Cleveland, Ohio.	Conversion to No. 2 oil.
	U.S. clipper dredge Genesee, various harbors on Lake Michigan.	Install smoke detector.
National Aeronautics and Space Administration.	Michoud Assembly Facility, Marshall Space Flight Center, New Orleans, La.	Fuel conversion, incinerator.
	Goddard Space Flight Center, Greenbelt, Md.	Fuel conversion.
	Ames Research Center, Moffett Field, Calif.	Fume scrubber, incinerator afterburner.
	Langley Research Center, Hampton Va.	To study control requirements of heating plant.
Department of Justice	Federal Reformatory, Petersburg, Va.	Fuel conversion.
Department of Commerce	National Bureau of Standards, Gaithersburg, Md.	Do.
General Services Administration	Federal Office Building, Brooklyn, N.Y.	Do.
	U.S. Courthouse and Federal Building, Chicago, Ill.	Do.
	Heating plant, Philadelphia, Pa.	Do.
	Bronx Central Station, Bronx, N.Y.	Do.
	Federal Office Building, New York, N.Y.	Do.
	Courthouse and Federal Building, Brooklyn, N.Y.	Do.
	Post Office and Courthouse, Newark, N.J.	Do.
	Somerville Depot, Somerville, N.J.	Do.

	do	Do.
	Madison Square Post Office, New York, N.Y.	Do.
	Post Office and Courthouse, Camden, N.J.	Do.
	Post Office, Jersey City, N.J.	Do.
	North Philadelphia Postal Station, Philadelphia, Pa.	Do.
	Federal Building, Newark, N.J.	Do.
	Post Office, Paterson, N.J.	Do.
	Federal Building and U.S. Courthouse, Hammond, Ind.	Do.
	Post Office, Flushing, N.Y.	Do.
	Post Office, Jamaica, N.Y.	Do.
	U.S. Post Office, Oak Park, Ill.	Do.

Agency	Location	Problem
General Services Administration—Con.	Post Office, East Orange, N.J.	Fuel conversion.
	U.S. Post Office, Maywood, Ill.	Do.
	U.S. Post Office, Waukegan, Ill.	Do.
	Post Office, Long Island, N.Y.	Do.
	Englewood Postal Station, Chicago, Ill.	Do.
	Post Office Elmhurst, Ill.	Do.
	Federal Center Building 47, Denver, Colo.	Do.
	Post Office, Minneapolis, Minn.	Repair heating plant and fuel conversion.
Tennessee Valley Authority	Shawnee Steam Plant, Tenn.	Particulates.
	Colbert Steam Plant, Tenn.	Do.
	Widow's Creek Steam Plant, Tennessee	Do.
	Gallatin Steam Plant, Tennessee	Do.
	Power Building, Chattanooga, Tenn.	Install dust collector or fuel conversion.
Department of Health, Education, and Welfare.	PHS Hospital, Fort Worth, Tex.	Incinerator, combustion controls.
	PHS Hospital, Lexington, Ky.	Fuel conversion, incinerator.
	PHS Hospital, Boston, Mass.	Incinerator.
	Howard University, Washington, D.C.	Boiler replacement truck for trash removal.
	FDA Research Facility, Beltsville, Md.	Incinerator.
Veterans' Administration	VA Hospital, Ann Arbor, Mich.	Fuel conversion.
	VA Hospital, Battle Creek, Mich.	Do.
	VA Hospital, Castle Point, N.Y.	Precision of landfill
	Veterans Center, Dublin, Ga.	Fuel conversion and incinerator.
	VA Hospital, Durham County, N.C.	Fuel conversion.
	VA Hospital, Erie, Pa.	Do.
	VA Center, Fargo, N. Dak.	Do.
	VA Hospital, Fayetteville, N.C.	Do.
	VA Hospital, Grand Junction, Colo.	Do.
	VA Hospital, Iron Mountain, Mich.	Do.
	VA Hospital—Jefferson Barracks, St. Louis, Mo.	Do.
	VA Hospital, Kansas City, Mo.	Do.
	VA Hospital, Knoxville, Iowa	Do.
	VA Hospital, Lexington, Ky.	Do.
	VA Hospital, Louisville, Ky.	Do.
	VA Hospital, Lyons, N.J.	Do.
	VA Hospital, Madison, Wis.	Do.
	VA Hospital, Montrose, N.Y.	Fuel conversion, new incinerator.
	VA Hospital, Sheridan, Wyo.	Fuel conversion.
	VA Hospital, Spokane, Wash.	Do.
	VA Hospital, Tomah, Wis.	Do.
	VA Hospital, Vancouver, Wash.	Do.
	VA Hospital, West Haven, Conn.	Do.
	VA Hospital, Aspinwall, Pa.	Replace boiler.
	VA Hospital, Salem, Va.	Sanitary landfill, replace boilers.
	VA Hospital, Mountain Home, Tenn.	Replace boilers.
	VA Hospital, Chillicothe, Ohio	Replace boiler plant, develop sanitary fill.

AIR POLLUTION ABATEMENT BY FEDERAL FACILITIES

SECOND REPORT

OF THE

SECRETARY OF HEALTH, EDUCATION, AND WELFARE

TO THE

UNITED STATES CONGRESS

PURSUANT TO

Public Law 90-148
THE AIR QUALITY ACT OF 1967

JANUARY 1969

MARCH 4, 1969.—Ordered to be printed

U.S. GOVERNMENT PRINTING OFFICE
25-140 O WASHINGTON : 1969

SENATE RESOLUTION 88

Submitted by Mr. Randolph of West Virginia

IN THE SENATE OF THE UNITED STATES,
Agreed to March 4, 1969.

Resolved, That there be printed with illustrations as a Senate document the report of the Secretary of Health, Education, and Welfare, entitled "Air Pollution Abatement by Federal Facilities" submitted to the Congress in accordance with section 306, Public Law 90-148, the Air Quality Act of 1967, and that there be printed two thousand five hundred additional copies of such document for the use of the Committee on Public Works.

FRANCIS R. VALEO,
Secretary.

LETTER OF TRANSMITTAL

THE SECRETARY OF HEALTH, EDUCATION, AND WELFARE,
Washington, D.C., January 17, 1969.

Hon. HUBERT H. HUMPHREY,
President of the Senate,
Washington, D.C.

DEAR MR. PRESIDENT: In accordance with the provisions of title I, section 111(b) of Public Law 90-148 (the Air Quality Act of 1967), I am pleased to transmit the report on measures being taken by Federal agencies to control the emission of air pollutants from Federal facilities.

It is the intent of this report to describe in detail such progress as as has been made toward controlling air pollution from sources for which Federal departments or agencies have jurisdiction.

Sincerely,

WILBUR J. COHEN,
Secretary.

AIR POLLUTION ABATEMENT BY FEDERAL FACILITIES

I. INTRODUCTION

The Air Quality Act of 1967, as did the earlier Clean Air Act, as amended, emphasizes the need for Federal leadership and assistance to State and local agencies in the control of air pollution. The act also indicates that the Federal agencies shall cooperate with the Department of Health, Education, and Welfare and with any air pollution control agency in preventing and controlling air pollution. It also provides, at the discretion of the Secretary, for the establishment of classes of air pollution sources for which limited permits could be issued, and it further requires the Secretary to submit an annual report to the Congress on the status of such permits and compliance therewith.

In addition to this act, the program of abatement and control of air pollution from Federal facilities is governed by Executive Order 11282, dated May 26, 1966, entitled, "Control of Pollution Originating From Federal Installations"; the "Performance Standards and Techniques of Measurement" prescribed by the Secretary of Health, Education, and Welfare, issued June 2, 1966, and subsequently amended, in response to "Section 5 Standards" of Executive Order 11282; Bureau of the Budget Circular No. A–78 issued on August 6, 1966, to the heads of executive departments and establishments.

The issuance of limited exemptions, as provided under the Executive order, has been used as a control device, rather than development of a permit system, as authorized in the Air Quality Act of 1967.

The staff of the Federal Facilities Section, National Air Pollution Control Administration, devotes full time to the surveillance of air pollution problems arising from Federal activities, the extension of technical assistance to agencies and departments and to studies for scheduling necessary improvements to control emissions from Federal establishments. This staff also assists the Bureau of the Budget in technical and administrative review of the 5-year phased and orderly plans prepared by the various governmental groups concerned in this abatement activity.

II. ABATEMENT PLAN

As called for by Executive Order 11282 and Bureau of the Budget Circular No. A–78, the departments and agencies submitted revisions of their original phased and orderly plans on July 1, 1968, and also, for the first time, furnished reports of progress on projects which could be funded within available appropriations.

The revised plans are concerned principally with proposed abatement actions to be undertaken during fiscal year 1970. Appendix A contains the detailed proposals for abatement activities which have been recommended for funding by the Bureau of the Budget for fiscal year 1970.

On June 20, 1968, the Secretary of Health, Education, and Welfare announced that 32 Air Quality Control Regions would be designated during the next 12 months. These regions, in the order in which designation is expected to occur, are the following:

1. Washington, D.C.
2. New York
3. Chicago
4. Philadelphia
5. Denver
6. Los Angeles
7. St. Louis
8. Boston
9. Cincinnati
10. San Francisco
11. Cleveland
12. Pittsburgh
13. Buffalo
14. Kansas City
15. Detroit
16. Baltimore
17. Hartford
18. Indianapolis
19. Minneapolis-St. Paul
20. Milwaukee
21. Providence
22. Seattle-Tacoma
23. Louisville
24. Dayton
25. Phoenix
26. Houston
27. Dallas-Fort Worth
28. San Antonio
29. Birmingham
30. Toledo
31. Steubenville
32. Chattanooga

Under the Air Quality Act of 1967, designation of regions is a fundamental step leading toward action by State governments to adopt and enforce standards to control air pollution on a regional basis.

Once regions are designated, the Air Quality Act of 1967 requires that States set ambient air quality standards for the regions within 9 months following the publication of criteria for particular pollutants. An additional 6 months are allowed for the development of an implementing plan which would include emission standards for pollution sources. This standard-setting process is expected to begin in the first regions early in calendar year 1969.

Almost all of the Federal facility projects included in the President's budget for fiscal year 1970 are located in the 32 Air Quality Control Regions listed above. The funding of these projects will permit Federal facilities to provide leadership in abating air pollution in these regions.

A few additional projects are included in the President's 1970 budget because they are violations of local codes or are designated to abate toxic emissions which involve imminent danger to health. A project at one installation is included because of excessive complaints from the public.

III. EXEMPTIONS

The Department of Defense requested and was granted a 1-year exemption (to October 1, 1969) from the provisions of section 76.5, title 42, Code of Federal Regulations, part 76, dated March 17, 1967. This section required control of sulfur oxide emissions in the Chicago and New York Standard Consolidated Areas and the Standard Metropolitan Statistical Area of Philadelphia by October 1, 1968. It was impossible for the Department of Defense to meet this deadline with regard to a number of its facilities which require large capital expenditures for conversion of their boilers. The Department's fiscal year 1969 budget had progressed too far to allow the changes necessary to provide for these conversions. The President's fiscal year 1970 budget will allow the Department to undertake substantially all of these conversions.

The Atomic Energy Commission requested an exemption from the provisions of the same section requiring control of sulfur oxides in the New York and Chicago Standard Consolidated Areas for the Brookhaven and the Argonne National Laboratories, respectively. The request was based on the denial of funds by the Joint Committee on Atomic Energy for conversion to lower sulfur fuels at these laboratories. An exemption for 1 year (to October 1, 1969) has been granted to the Atomic Energy Commission for the Argonne and Brookhaven sites on the proviso that the Commission again request funds for fiscal year 1970 to convert the heating plant at Argonne to natural gas and that efforts be made to secure 1 percent sulfur fuel oil for Brookhaven.

The Joint Committee on Atomic Energy in its denial of funds for fiscal year 1969, urged a delay in the Argonne project pending an expected breakthrough on research which would produce an economically acceptable method of removing sulfur oxides from stack gases. Atomic Energy Commission representatives have been informed by the National Air Pollution Control Administration that the current research on developing control techniques for removing sulfur oxides from stack gases is directed to produce methodology suited for control of large fossil fuel-burning power-generating sources and not directed to heating plants as small as that at Argonne National Laboratory. This laboratory is within the boundaries of the Metropolitan Chicago Interstate Air Quality Control Region, which is identical to the Chicago Standard Consolidated Area. Since the region will be expected to have air pollution control standards and regulations within the next 15 months, a conversion of this facility now would be consistent with providing Federal leadership, as called for in Executive Order 11282.

The Department of Transportation requested, and was granted, a 1-year exemption for fuel conversion at the Coast Guard base on Governor's Island, N.Y. This base is partially converted to burn No. 2 distillate fuel oil, and the exemption was granted with the

proviso that conversion be completed as soon as additional funds become available. It is expected that this task will be completed before October 1, 1969.

Similarly, the Department of Agriculture requested an exemption from the sulfur-oxide regulation for the heating plant at the Plum Island, Long Island, Animal Disease Laboratory. A 1-year exemption also was granted in this case, on the proviso that the laboratory use the lowest possible sulfur content fuel oil which can be obtained from the General Services Administration for use at this site.

IV. REMEDIAL ACTIONS

Actions to abate air pollution from Federal facilities were reported this year, for the first time, to the Bureau of the Budget. As required by Bureau of the Budget Circular No. A-78, these reports arrived on July 1, 1968, and reflect conditions as of April 1, 1968.

A summary of these reports reveals that 442 remedial actions were reported for 387 installations located in 45 States, the District of Columbia, Puerto Rico, and Guam. With few exceptions, the remedial actions fall into the following categories:

1. Elimination of open burning of refuse.
2. Installation of new incinerators or upgrading of existing incinerators to meet Federal regulations.
3. Reduction of particulate emissions from heating and power plants by:
    a. Repairs to old plants.
    b. Construction of new plants.
    c. Improvement of particulate collectors.
    d. Installation or improvement of particulate monitors.
    e. Conversion from coal to either gas or fuel oil.
4. Reduction of sulfur oxide emissions from heating plants by:
    a. Using same type of fuel but of lower sulfur content.
    b. Converting to a different fuel of lower sulfur content.
5. Reduction of gasoline and solvent vapor losses from storage tanks.
6. Awarding of contracts during the year to remedy specific situations.
7. Initiation of studies, design and/or engineering actions to prepare cost estimates.

Appendix B presents an overall summary of accomplishmants by agency and by remedial action category.

Appendix C presents a detailed list of installations, arranged by agency, reporting the above listed remedial actions.

These remedial actions reflect, in part, normal air pollution control activities of the agencies funded from their regular budgets as well as actions stimulated and accelerated by the promulgation of Executive Order 11282 and the need to prepare the 5-year phased and orderly plan. Congressional action on fiscal year 1969 budget requests had not been completed by April 1, 1968, and therefore, most of these projects represent relatively small expenditures of funds already available to solve relatively simple and inexpensive problems. Abatement actions at large installations or on very expensive projects generally must await funding. Installation of electrostatic precipitators at the large Tennessee Valley Authority powerplants is an exception to this situation, because of alternate sources of funds.

25-140 O—69——2

These reports also reflect favorably on the efforts of agencies to comply with the strict sulfur-oxide regulations governing the New York and Chicago standard consolidated areas and the standard Metropolitan Statistical Area of Philadelphia.

Fuels for use in these areas by the civilian agencies are obtained principally by the General Services Administration. Inquiry to the General Services Administration elicited the information that all fuels used in the Chicago standard consolidated area are in conformity with the requirements of the Executive order.

Attempts to secure bids on fuels which would meet the Executive order regulations for New York and Philadelphia failed for the most part. The limited response required a 64 percent premium over costs of existing fuel. Readvertising for a maximum of 1 percent sulfur content brought good response resulting in an 11 percent to 16 percent increase in costs over previous higher sulfur fuels. These responses were considered acceptable. This means that, for these areas, a No. 4 fuel oil with 0.7 percent sulfur and a No. 6 fuel oil with 1.0 percent sulfur maximum will be used for the 1968–69 heating season.

This success in securing fuel oil with 1 percent or slightly less than 1 percent sulfur is encouraging and forecasts a considerable improvement in future sulfur-oxide emissions; additional improvements will accrue as a result of conversions to natural gas.

V. WASHINGTON, D.C., METROPOLITAN AREA

Considerable progress in controlling air pollution has been made by Federal facilities in the area following the National Capital Metropolitan Area Interstate Air Pollution Abatement Conference held by the Department of Health, Education, and Welfare in December 1967. Open burning has been discontinued at Kenilworth Dump in the District of Columbia and a sanitary landfill has been started. The Department of Health, Education, and Welfare, the Department of the Interior and the government of Washington, D.C. were instrumental in effecting this long-sought change.

The Department of Commerce has completed conversion of the heating plant at the National Bureau of Standards in Gaithersburg, Md., to burn natural gas, with No. 2 fuel oil as standby; and the Treasury Department has modified the classified-waste incinerator at the Bureau of Engraving and Printing in Washington, D.C. Pending funds for replacement, an incinerator at the Agricultural Research Station in Beltsville, Md., has been repaired by the Department of Agriculture.

Conversion of heating plants to burn natural gas is underway at the Goddard Space Flight Center of the National Aeronautics and Space Administration in Greenbelt, Md., and at the National Zoological Park of the Smithsonian Institution in Washington, D.C.

With respect to the Department of Health, Education, and Welfare, the Food and Drug Administration in Beltsville, Md., has reduced particulate emissions from a faulty incinerator by making operational changes; several incinerators have been eliminated on the Howard University campus in Washington, D.C., by transporting refuse to the District of Columbia incinerators; St. Elizabeth's Hospital in the District has contracted for replacement of a faulty pathological incinerator, has installed smoke meters on coal and oil-burning boilers and has secured funds for equipping the main refuse incinerator with air pollution control equipment; the National Institutes of Health in Bethesda, Md., is now using a No. 6 fuel oil with a maximum sulfur content of 0.5 percent, is redesigning classified waste incinerators for installation of both afterburners and water scrubbers, and is engaged in a joint effort with the Department of the Army and the Department of the Navy to design and construct a large general waste incinerator to serve the National Institutes of Health, the Naval Medical Center, and Walter Reed Hospital and Annex. Construction will be at the annex site in Maryland. The Department of the Army has been issued a permit for land use for this project and design has been started.

The General Services Administration, as anticipated, is playing an important role in the Washington, D.C. metropolitan area, as elsewhere, with respect to procurement of low-sulfur fuel. Since November 1967, all fuel oil procured for the Department of Defense facilities in the Washington area by the General Services Administration has contained 2 percent sulfur. For the 1968–69 heating season, fuels have

been secured at 1.5 percent sulfur, which is in accord with the recommendations of the Washington abatement conference. Furthermore, it is expected that for the 1969–70 heating season 1 percent sulfur fuels will be provided. Department of Defense facilities involved are the following:

Arlington Hall Station, Arlington, Va.;
Pentagon Building, Arlington, Va.;
Cameron Station, Alexandria, Va.;
Fort Belvoir, Springfield, Va.;
Harry Diamond Laboratories, Washington, D.C.;
Fort Leslie J. McNair, Washington, D.C.;
Walter Reed Army Medical Center, Washington, D.C.;
N. G. Camp Sims, Washington, D.C.;
Walter Reed Army Medical Center (Forest Glen Annex), Maryland;
Army Map Service, Montgomery County, Md.;
Andrews Air Force Base, Maryland;
Naval Research Laboratory, Washington, D.C.;
Marine Barracks, Washington, D.C.;
Naval Communications Station, Cheltenham, Md.;
Naval Medical Center, Bethesda, Md.; and
Naval Ordnance Laboratory, White Oaks, Md.

Additional activities of the General Services Administration in this area have resulted in the replacement of three boilers, previously burning number 6 fuel oil, with two gas-fired boilers at the old Bureau of Standards property on Connecticut Avenue in the District of Columbia. The General Services Administration also has reported that all of the major coal-burning steam plants operated by the General Services Administration now are using coal containing 1 percent sulfur or less.

Remaining problems of air pollution abatement in Federal facilities in and around Washington, D.C., generally are minor and work is proceeding on many of these at this time.

VI. MISCELLANEOUS ACTIVITIES

During calendar year 1968, emission inventories of all 77 Federal facilities in the Kansas City area were completed and entered in the record of the second session of the Kansas City, Kans.-Kansas City, Mo. Interstate Air Pollution Abatement Conference. A similar inventory was completed of the 185 Federal facilities in the Philadelphia, Pa., area in conjunction with the Delaware Valley regional air quality program which is being conducted cooperatively by Federal, State, and local agencies.

In view of the mandate for Federal facilities to exhibit leadership in abating air pollution, inventories of emissions from Federal facilities have been completed in Washington, D.C., New York, Chicago, Philadelphia, Chattanooga, and Detroit and started in Denver, St. Louis, Boston, and San Francisco. Eventually, all 32 regions will be completely inventoried. Information will be helpful to the facilities themselves and will be important in any overall area emission studies which must be carried out before control programs are developed by States and communities concerned within each region.

Special studies also are underway concerning air pollution problems and control practices in Federal foundries, ammonia oxidation plants used to manufacture nitric acid, and sulfuric acid manufacturing plants. Information secured from these studies will be helpful in developing improved control techniques for these air pollutants.

The Department of Defense again has included proposals for control of emissions from the Volunteer Army ammunition plant in Hamilton County, Tenn. Proposals for this plant have been included in fiscal year 1969 plans but were not funded by Congress. This plant probably is the worst single Federal source of air pollution, principally oxides of nitrogen, in the United States. It has been the source of complaints, congressional inquiries and general citizen dissatisfaction in its vicinity. Failure to fund the 1969 project was a distinct disappointment and it is hoped that corrective measures will be funded in fiscal year 1970.

Technical assistance on specific problems associated with boiler operations was given to the Department of Defense, Veterans' Administration, and the Department of Health, Education, and Welfare. Similar help concerning incinerators was given to the Smithsonian Institution and to the Departments of Defense, Interior, and Agriculture.

A conference was held with representatives of the Corps of Engineers (civil works) concerning the disposal of debris from New York Harbor. Representatives of the Corps were reminded that the pit incinerator being constructed at Caven Point, N.J., in its proposed form, may be inadequate to meet the standards concerning particulate emissions. If this should prove to be true following testing of this device, further design and engineering will be necessary to secure compliance with the regulations.

A carbon monoxide control study related to automotive traffic was started at selected border stations at the request of the Public Buildings Service of the General Services Administration.

The Washington, D.C., Air Pollution Division and the National Park Service of the Department of the Interior were advised concerning an incinerator designed for the destruction of brush and logs. These agencies are attempting to dispose of this waste in a manner which hopefully will replace the current open burning. Specialized activities have been continued to assure the control of exhaust products from missiles and rockets powered with highly toxic propellants. These activities involved close cooperation and interagency liaison with the Department of Defense, National Aeronautics and Space Administration, Atomic Energy Commission, Armed Services Explosives Safety Board, and the National Academy of Sciences-National Research Council. During the year, not a single rocket motor containing beryllium propellant was fired in the open air of the continental United States.

In the interest of providing further assistance during the year, the Federal Facilities Section distributed several hundred copies of the 892-page publication titled "Air Pollution Engineering Manual" to the Federal agencies. Also distributed for comment and technical criticism was the "Interim Guide to Good Practice for Selecting Incinerators for Federal Facilities."

The Section also participated in a training course at Durham, N.C., for approximately 70 engineers of the Army Materiel Command and in a seminar at the Army Environmental Health Agency, Edgewood Arsenal, Edgewood, Md., with representatives of the Army Surgeon General's Office, the Bureau of the Budget and the Federal Water Pollution Control Administration, to review the operation of the 5-year phased and orderly plan.

VII. CONCLUSION

The Federal departments and agencies again this year evidence excellent cooperation with the Department of Health, Education, and Welfare and the Bureau of the Budget for purposes of preventing and controlling air pollution. The reports of progress highlight both the efforts and the intentions of the agencies. With sufficient funding, there is no reason why air pollution control by Federal agencies should not be successful. Announcement of the establishment of the first 32 air quality control regions by the National Air Pollution Control Administration has given further impetus to this program and has defined more sharply than heretofore areas to which specific attention must be provided both by the Federal Government and by State and local organizations.

Sufficient funding will enable prompt abatement of air pollution from Federal establishments.

APPENDIX A

FISCAL YEAR 1979 PROJECTS TO BE RECOMMENDED BY THE PRESIDENT

Agency	Installation	Proposed action
Department of Agriculture	Agricultural Research Center, Beltsville, Md.	Construct new incinerator for Animal Husbandry Meats Laboratory and a new pathological incinerator for Building 125A, Animal Parasite Station, area 1. Convert Heating Plant 307BA, area 3 to gas with No. 2 fuel oil as standby.
Atomic Energy Commission	Feed Materials Production Center, Fernald, Ohio	Install sanitary landfill and 2 special purpose incinerators.
	Argonne National Laboratory, Argonne, Ill	Convert heating plant to natural gas.
Department of Commerce	U.S. Merchant Marine Academy, Kings Point, N.Y.	Conversion of heating plant to No. 2 fuel oil or to gas with oil standby depending on results of engineering feasibility study now underway.
General Services Administration	Post Office and Courthouse, East St. Louis, Ill.	Convert boiler to oil or gas.
	AEC Building, Germantown, Md.	Install wet scrubber on incinerator.
	Military Personnel Records Center, Overland, Mo.	Convert boiler from coal to No. 2 fuel oil.
	Post office (Back Bay annex), Boston, Mass.	Convert to oil.
Department of Health, Education, and Welfare	Public Health Service hospital, Detroit, Mich.	Replace boilers and install 2 incinerators.
Smithsonian Institution	National Zoological Park, Washington, D.C.	Improve control of incinerator by wet scrubber and convert coal steamplant to gas.
Tennessee Valley Authority	Shawnee steamplant, McCracken County, Ky.	Complete installation of electrostatic precipitators on all 10 units.
	Widows Creek steamplant, Jackson County, Ala.	Upgrading electrostatic precipitators on units 7 and 8 will be continued.
	Gallatin steamplant, Sumner County, Tenn.	Complete installation of electrostatic precipitators.
Veterans' Administration	VA Hospital, Bronx, N.Y.	Replace 3 boilers with 1 boiler and convert 2 boilers to gas and No. 2 fuel oil.
	VA hospital, Butler, Pa.	Replace 3 boilers with 2 boilers burning gas and No. 2 fuel oil.
	VA hospital, Pittsburgh, Pa. (UH)	Convert 4 boilers to gas and No. 2 fuel oil.
	VA hospital, Pittsburgh, Pa. (NP)	Convert 3 boilers to gas and No. 2 fuel oil.
	VA center, Dayton, Ohio	Convert 4 boilers to gas and No. 2 fuel oil.
	VA hospital, Cincinnati, Ohio (Fort Thomas)	Replace 4 boilers with 2 burning gas and No. 2 fuel oil.
	VA hospital, Brecksville, Ohio	Replace 1 boiler and convert 2 boilers to gas and No. 2 fuel oil.
Department of Defense:		
Air Force	Davis-Monthan Air Force Base, Tucson, Ariz.	Install a 75-ton-per-day scrap metal smelter complete with shredding device, automatic loading and weighing equipment, multicombustion chamber design, high-temperature refractory, an automatic metal reclaiming system, dross remover, and air pollution abatement control equipment.
	Bradley Air National Guard, Windsor Locks, Conn.	Install smoke density recorder meter on boiler.
	Eglin Air Force Base, Ft. Walton Beach, Fla.	Install incinerator in marketing and redistribution area; modify 5 POL storage tanks to floating roof configuration; install wet scrubber for asphalt plant; install catalytic combustion chamber and ducts over gas vents of each of 3 install tanks.
	Scott Air Force Base, Belleville, Ill	Install sub merged fill-pipe in 7 underground aviation gas tanks.
	Andrews Air Force Base, Camp Springs, Md.	Enlarge Building 34-D (Navy plant) to contain oil-fired equipment and eliminate Building 3743. Convert from coal to low-sulfur fuel oil (No. 2) all boilers in Buildings 3039, 3212, 3755, and 4231. Install smoke density meters to all existing boilers over 10 million BTU input capacity.
	McGuire Air Force Base, Burlington County, N.J.	Convert boilers in Buildings 21-01, 34-02, to natural gas; Buildings 16-23, 18-07, 24-01, 33-72, 34-10, and 19-05 to No. 2 fuel oil. Same for Building 18-01.

1485

	McGuire Air Force Base ANG areas, Wrightstown, N.J.	Convert 2 oil burners from No. 4 fuel oil to No. 2 fuel oil.
	Lockport Air Force Station, Lockport, N.Y.	Design mechanical filters for boilerhouse stack at main boiler plant.
	Wright-Patterson Air Force Base, Greene County, Ohio.	Design gas scrubber for incinerator in building 202.
	Brooks Air Force Base, San Antonio, Tex.	Design refuse incinerator to eliminate sanitary landfill operation because of limited land.
	Carswell Air Force Base, Fort Worth, Tex.	Repair existing incinerator in building 1730. Base refuse to be disposed of by contract in fiscal year 1970.
	McChord Air Force Base, Tacoma, Wash.	Construct incinerator to eliminate burn and cover garbage refuse.
Army	General Mitchell ANG Base, Milwaukee, Wis.	Install smoke density recording meter.
	Volunteer Army Ammunition Plant, Hamilton County, Tenn.	For TNT production area, complete installation of instrumentation for TNT waste acid fume recovery system; install additional bubble-cap towers to increase absorption capacity of TNT waste acid recoveries; investigate more efficient air jet to decrease volume of fumes from bi-oil at bi-house to permit introduction of fumes into fume recovery line; make absorption study to determine optimum TNT waste acid recovery conditions; install scrubbers to remove nitrogen oxides from recovery bubble-cap absorption column stack gas and from wash house gases; improve performance of fume lines between mono and bi-houses and acid recovery buildings. For sand acid production area, the use of natural gas is awaiting a gas contract; testing to be done to determine feasibility of a mist filter to replace the electrostatic precipitators and the Nelson fog filters; possible installation of a combustion unit for nitric acid concentration and nitrate tanks; for Ammonia Oxidation Plant, improve process control and consider use of catalytic combustion units to eliminate oxides of nitrogen. For the Red Water Incineration Plant, use of natural gas is awaiting contract; install an improved fuel system and a wet scrubbing system. Problem of eliminating open burning area is under study. Recommendations also have been submitted for a completely modern TNT plant with allied acid facilities to reduce pollution costs.
	Joliet Army Ammunition Plant, Joliet, Ill.	Replacement of open burning by a sanitary landfill; install mist eliminator equipment for sulfuric acid concentrators and convert to natural gas; design catalytic combustion units for ammonia oxidation plants; install mist eliminator equipment for steam production units and for pellite producing units; install fume scrubbing system for TNT recovery buildings and for tetryl recovery building; convert to natural gas and install particulate collectors for red water incinerators; use lower sulfur oil for central heating plants and install sanitary landfill for nonexplosive material to eliminate open burning at the load assembly pack unit.
	Fort Benjamin Harrison, Indianapolis, Ind.	Design conversion of central coal-fired heating plant to natural gas; design to connect that plant to heating plant No. 2 with steam line; design conversion to No. 2 fuel oil for 2 consolidated manpacks.
	U.S. Army Reserve Center, Indianapolis, Ind.	Convert coal-fired heating system to natural gas.
	Picatinny Arsenal, Dover, N.J.	Conversion of coal-fired boilers to natural gas with low-sulfur fuel oil standby; use of low-sulfur fuel oil at oil-fired heating plants.
	Granite City Army Depot, Granite City, Ill.	Construct incinerator to eliminate 2 open burning areas.
	Fort Sam Houston, San Antonio, Tex.	Install system to reclaim used oil thereby eliminating open burning from salvage oil pit.
	Aberdeen Proving Ground, Aberdeen, Md.	Install submerged inlets on gasoline storage tanks to reduce loss of gasoline through evaporation.
	Edgewood Arsenal, Edgewood, Md.	Design of new incinerator for waste disposal.
	Fort George Meade, Odenton, Md.	Design conversion of coal-fired heating plants to either oil- or gas-fired units depending upon economics study.
	Valley Forge General Hospital, Phoenixville, Pa.	Replace short stacks on 3 boilers with breeching to existing 100-foot brick stacks and install fly ash collection hoppers; install photoelectric smoke detectors on boilers over 10 M B.t.u. per hour input. Design replacement incinerator for a larger facility with smoke and particulate abatement equipment.

See footnote at end of table, p. 15.

APPENDIX A—Continued

FISCAL YEAR 1970 PROJECTS TO BE RECOMMENDED BY THE PRESIDENT

Agency	Installation	Proposed action
Department of Defense—Continued		
Army—Continued	Frankford Arsenal, Philadelphia, Pa	Design for conversion from No. 6 oil to combination of No. 2 oil and gas.
	Fort Dix, Burlington, N.J	Construct stoomline to an oil-fired plant in reception center and then remove coal-fired boiler in building 2604.
	Fort Hancock, Highlands, N.J	Change fuel from coal to gas with oil standby at central heating plant.
	Arlington Hall Station, Arlington, Va	Renovate and rebuild incinerators.
	Fort Belvoir, Fairfax County, Va	Fuel conversion to natural gas with low-sulfur fuel oil as standby for 2 boilers using coal (10-100 M B.T.U. per hour).
	Fort McNair, Washington, D.C	Replace underground gasoline storage tank and include submerged type fill pipe to prevent gasoline loss.
	Michigan missile plant, Warren, Mich	Conversion of 2 boilers to gas fuel from coal.
Navy	Naval Air Station, Alameda, Calif	Provide pressure breather valves for aviation gas storage tanks 97A to 97E; set control at 2.5 p.s.i. Phase out tanks 342A and 342B, fiscal year 1972 or sooner.
	Marine Corps Supply Center, Barstow, Calif	Install on-station sanitary landfill to replace open-pit burning.
	Naval Weapons Station, Concord, Calif	Provide multichamber incinerator with afterburner or install a wet pulping system.
	San Francisco Bay Naval Shipyard, Hunters Point, San Francisco, Calif.	Provide 2 direct flame afterburners for bake ovens in building 211 and building 271. Design and engineering studies to replace a dry pulp paper disintegrator with a wet pulping system.
	San Francisco Bay Naval Shipyard, Mare Island, Vallejo, Calif.	Improve ventilation of building 53. Increase frequency of cleanout of oil scrubber and replace filter pads in the scrubber more frequently. These changes are directed at odor control from rubber milling operations.
	Fleet Training Center, Naval Station, San Diego, Calif	Construct air pollution control system to eliminate smoke from this activity.
	Naval Fuel Depot, San Pedro, Calif	Installation of a vapor collection and flare system to collect and burn vapors during filling operations for a truck loading facility and four fuel storage tanks.
	Naval Station, Treasure Island, San Francisco, Calif	Engineering study to provide baghouse filter on cyclone exhaust from a classified paper disintegrator at building 649.
	Marine Corps Air Station, Kaneohe Bay, Honolulu, Hawaii.	Install sanitary landfill to replace open burning dump.
	Fleet Training Group, Pearl Harbor, Honolulu, Hawaii	Design smoke abatement facility for firefighting training school.
	Naval Ordnance Station, Forest Park, Ill	Design new incinerator with air pollution control equipment.
	Naval Training Center, Great Lakes, Ill	Install afterburner system to eliminate smoke from the firefighting training school.
	Naval Air Station, Olathe, Kans	Design smoke control system for firefighting training operation.
	Naval Shipyard, Boston, Mass	Design high-efficiency collector to control particulates from powerplant.
	Naval Communications Station, Cheltenham, Md	Install wet scrubber to control emissions from refuse incinerator.
	Naval Ship Research and Development Center, Carderock, Md.	Install smoke detectors on heating plant in building 6.
	Naval Ammunition Depot, Earle, N.J	Convert from No. 4 residual fuel oil to No. 2 distillate oil; eliminate open burning and dispose of lumber by a chipper.
	Naval Air Station, Brooklyn, N.Y	Convert from No. 6 and No. 4 residual fuel oil to No. 2 distillate in building No. 5 and building No. 4, respectively.
	Naval Hospital, St. Albans, N.Y	Convert from No. 6 residual fuel oil to No. 2 distillate oil in building 64.
	Naval Supply Center, Craney Island, Norfolk, Va	Installation of smoke detectors and alarms on boilers; provide waste oil destruction to replace waste oil pit, construct new incinerator or burn in city incinerator.
	Naval Damage Control Training Center, Philadelphia, Pa.	Construct smoke elimination system for this fire center.

Corps of Engineers (civil functions)	Potomac and Anacostia Rivers, Washington, D.C.	Install incinerator to dispose of drift and debris collected from these rivers. May be open-pit type or mounted on a barge. Decision rests upon prototype open-pit device operation at Caven Point, N.J.
	Baltimore Harbor, Baltimore, Md. (drift removal)	Install overfire air pit incinerator at Fort McHenry.
	Puget Sound and tributary waters, Washington, D.C. (harbor debris disposal).	Continue interim landfill operation and conduct engineering study to determine best solution.
	Dipper dredge "Kewaunee," Lake Michigan	Install smoke detector, alarm, or recorder on vessel.

[1] Tentative listing supplied by the Bureau of the Budget, Dec. 27, 1968.

APPENDIX B

SUMMARY OF REMEDIAL ACTIONS BY FEDERAL DEPARTMENTS OR AGENCIES, FISCAL YEAR 1968

Department or agency	Progress reports	Remedial actions	Stopped open burning or poor incineration	New or upgraded incinerators	Replacement of heating plants	Existing heating plants improved	New or improved particulate collectors	Smoke or other monitor systems installed	Using lower sulfur content coal or fuel oil	Converted heating plant from coal or oil to gas	Converted to electricity	Reduced chemical or vapor emissions	Other[1]
Grand total	387	442	126	9	14	7	8	16	103	37	1	31	90
Defense:

APPENDIX C

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968

Agency	Installation	Actions
Department of Defense:		
Defense Supply Agency	Defense Supply Support Center, Philadelphia, Pa.	Conversion of steam boiler to gas-oil firing completed February 1968.
Army	Fort McClellan, Anniston, Ala.	Open burning discontinued during fiscal year 1968.
	Redstone Arsenal, Huntsville, Ala.	Installed vapor emission control devices in nine tanks during fiscal year 1968.
	Fort Rucker, Daleville, Ala.	10 coal-fired boilers replaced or converted to oil or gas during fiscal year 1968.
		28 furnaces converted to oil or gas.
	Fort Richardson, Anchorage, Alaska	Construction contract awarded January 1968. Completion scheduled for October 1968.
	Fort Wainwright, Fairbanks, Alaska	Open burning discontinued and sanitary landfill established in fiscal year 1968.
	Yuma Proving Grounds, Yuma, Ariz.	Open burning discontinued and sanitary landfill established.
		Vapor emission controls installed on all gasoline storage tanks during fiscal year 1968.
	Fort Chaffee, Fort Smith, Ark.	Open burning discontinued and sanitary landfill established during fiscal year 1968.
	Pine Bluff Arsenal, Pine Bluff, Ark.	Open burning and white phosphorous slag eliminated (shipping slag to TVA). Renovating incinerator—contract awarded February 1968. Operation scheduled for fiscal year 1969. Design study for criteria and cost estimate completed December 1967. Preliminary survey chlorine manufacture facility made in July 1967.
	Hunter Liggett Military Reservation, Jolon, Calif.	Sanitary landfill for refuse disposal established during fiscal year 1968.
	Fitzsimmons General Hospital, Aurora, Colo.	Discontinued use of one incinerator during fiscal year 1968.
	Rocky Mountain Arsenal, Denver, Colo.	3 monitoring stations installed March 1968. Submerged inlets on 2 storage tanks, fiscal year 1968.
	Fort Leslie J. McNair, Washington, D.C.	Residual fuel oil with a maximum sulfur content of 2 percent has been used since July 1, 1967.
	Walter Reed Army Medical Center (Main), Washington, D.C.	Do.
	Atlanta Army Depot, Forest Park, Ga.	Submerged inlets installed on oil underground tanks during fiscal year 1968.
	Fort Gordon, Augusta, Ga.	256 coal-fired furnaces removed from construction area. 4 gasoline tanks removed during fiscal year 1968.
	Fort McPherson, Atlanta, Ga.	Open burning discontinued. Waste disposed off post.
	Chicago USAR Center No. 1 (Mankato), Chicago, Ill. (East 71st St.)	Fuel oil containing maximum of 1 percent sulfur has been used since Dec. 1, 1967.
	Chicago USAR Center No. 2 (Gibson), Chicago, Ill. (West Cermak Rd.).	Do.
	Chicago USAR Center No. 3 (Lincolnwood), Chicago, Ill. (North Kedzie Ave.).	Do.
	Chicago USAR Center, Chicago, Ill. (South Cornell St.)	Do.
	Chicago USAR Center, Chicago, Ill. (South Exchange Ave.).	Do.
	Joliet Army Ammunition Plant, Joliet, Ill.	Preliminary engineering studies made on control of emissions from manufacturing processes. Negotiating design contract for upgrading coal-fired heating plants. Soliciting lower sulfur coal and oil.
	Missile site C-80, Arlington Heights, Ill.	Fuel oil containing maximum of 1 percent sulfur has been used since Dec. 1, 1967.
	Rock Island Arsenal, Rock Island, Ill.	Installed ½ of the abatement devices planned for metal plating shop in fiscal year 1968.
	Fort Sheridan, Highland Park, Ill.	Fuel oil containing maximum of 1 percent sulfur has been used since Dec. 1, 1967. Construction contract awarded January 1968 to convert heating plant from coal to gas. Completion date November 1968.

1490

APPENDIX C—Continued

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968—Continued

Agency	Installation	Actions
Department of Defense—Continued		
Army—Continued		
	Waukegan USAR Center, Waukegan, Ill.	Fuel oil containing maximum of 1 percent sulfur has been used since Dec. 1, 1967.
	Camp Atterbury, Edinburg, Ind.	Open burning discontinued.
	Sunflower Army Ammunition Plant, Lawrence, Kans.	Open burning of uncontaminated waste discontinued and landfill established fiscal year 1968. Awarded design contract Apr. 30, 1968 to convert steam plant from coal to natural gas and No. 2 fuel oil standby.
	Fort Knox, Louisville (Hardin, Meade, Bullitt Counties) Ky.	Open burning discontinued in fiscal year 1968.
	Army Map Service, Brookmont, Md.	Residual fuel oil containing maximum of 2 percent sulfur used since July 1, 1967.
	Fort George G. Meade, Odenton, Md.	Smoke detectors and recorders installed on 10 boilers during fiscal year 1968.
	Walter Reed Army Medical Center Annex, Forest Glen, Md.	Residual fuel oil containing maximum of 2 percent sulfur has been used since July 1, 1967.
	Boston Army Base, Boston, Mass.	Smoke detectors installed on 6 boilers in the Central Boiler Plant September 1967.
	Fort Devens, Ayer, Mass.	Incinerators have been inactivated during fiscal year 1968.
	Fort Leonard Wood, Waynesville, Mo.	Contract awarded to convert 8 coal-fired boilers and 181 coal-fired heating systems to oil-fired before 1969-60 heating season.
	Fort Missoula, Missoula, Mont.	Eight coal-fired boilers changed to gas in fiscal year 1968.
	Bayonne military ocean terminal, Bayonne, N.J.	Fuel oil procured for use after May 1, 1968, will meet New Jersey State limit for sulfur content.
	Burlington Army ammunition plant, Burlington, N.J.	Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Camden USAR Center, Camden, N.J.	Fuel oil containing maximum sulfur content of 1 percent in use since Nov. 1, 1967. Oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Fort Dix, Wrightstown, N.J.	Fuel oil containing 1 percent sulfur in use since Nov. 1, 1967. Procuring anthracite with 0.9 percent sulfur content for use in fiscal year 1969. Bituminous coal for use in fiscal year 1969 to contain 1 percent maximum sulfur. Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Fort Hancock, Highlands, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent maximum sulfur content. Procuring bituminous coal with maximum sulfur content of 1 percent for fiscal year 1969. Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Kearny USAR Center, Kearny, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum. Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Camp Kilmer, Edison, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum. Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Alexander Hamilton USAR Center, Lodi, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum. Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limit.
	Fort Monmouth, Eatontown, N.J.	All open burning discontinued as of May 22, 1967, and refuse buried in landfill. Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur and oil procured after May 1, 1968, will meet New Jersey State sulfur limits. Coal procured for use in fiscal year 1969 will contain 1 percent sulfur in bituminous and 0.9 percent in anthracite.
	Fort Monmouth Subpost, Charles Wood Area, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur and oil procured after May 1, 1968, will meet New Jersey State sulfur limits. Procuring anthracite containing 0.9 percent sulfur for use in fiscal year 1969.
	Sgt. J. J. Sadowski USAR Center, Newark, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur and oil procured after May 1, 1968, will meet New Jersey State sulfur limits.

Nixon USAR Center, Nixon, N.J.	Fuel oil procured after May 1, 1968, will meet New Jersey State sulfur limits.
Picatinny Arsenal, Dover, N.J.	Discontinued open burning and use of incinerator. Landfill established. Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur, and oil procured for use after May 1, 1968, will meet New Jersey State sulfur limits. Bituminous coal for use in fiscal year 1969 being procured with maximum sulfur content of 1 percent. Design contract being negotiated for fuel conversion to gas.
Philadelphia Air Defense Site, Pedricktown, N.J.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur, and oil procured after May 1, 1968, will meet New Jersey State sulfur limits.
Trenton USAR Center, Trenton, N.J.	Fuel oil procured for use after May 1, 1968, will meet New Jersey State sulfur limits.
Fort Wingate Army Depot, Gallup, N. Mex.	Open burning replaced by landfill in March 1967. Construction contract awarded Apr. 30, 1968, to convert coal-fired boilers to gas.
Army Pictorial Center, New York City (Long Island City), N.Y.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Brooklyn military ocean terminal, New York (Kings County), N.Y.	Fuel oil used after May 31, 1968, will contain 1 percent sulfur maximum.
Fort Hamilton, Brooklyn, N.Y.	Smoke recorders installed on 3 boilers. Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum. Design contract being negotiated for upgrading incinerators.
Brig. Gen. T. Roosevelt, Jr. USAR Center, Hempstead, N.Y.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Miller Army Airfield, Staten Island, N.Y.	Do.
Sgt. Joseph E. Muller USAR Center, New York City (East 238th St.), N.Y.	Do.
S. Sgt. V. Q. Kelly USAR Center, New York City (West 42d St.), N.Y.	Do.
2d Lt. Thomas J. McDonald USAR Center, New York City (Gothals Ave., Jamaica), N.Y.	Do.
Seneca Army Depot, Romulus, N.Y.	Changed from coal firing to oil burners on 3 boilers (building 319) during fiscal year 1968.
Fort Tilden USAR Center, New York City, N.Y.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Fort Totten, New York City, N.Y.	Inactive status since July 31, 1967.
USA Directorate General Support Maintenance Activity, Bellmore, N.Y.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Fort Wadsworth, New York City, N.Y.	Do.
Watervliet Arsenal, Watervliet, N.Y.	Open burning discontinued during fiscal year 1968. Wastes removed by contract.
Fort Bragg, Fayetteville, N.C.	Open burning discontinued during fiscal year 1968.
Umatilla Army Depot, Hermiston, Oreg.	Open burning discontinued and landfill established as of May 1, 1968. Incinerator plans canceled.
Frankford Arsenal, Philadelphia, Pa.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Norristown USAR Center, Norristown, Pa.	Anthracite containing 0.9 percent sulfur being procured for use in fiscal year 1969.
Valley Forge General Hospital, Phoenixville, Pa.	Fuel oil used since Nov. 1, 1967, contains 1 percent sulfur maximum.
Horsham USAR Center, Willow Grove, Pa.	Do.
Camp Bullis, San Antonio, Tex.	Open burning discontinued on July 1, 1967, and sanitary landfill established.
Fort Hood, Bell and Coryell Counties, Tex.	Do.
Fort Sam Houston, San Antonio, Tex.	Do.
Red River Army Depot, Texarkana (Bowie County), Tex.	Rubber previously burned is now stockpiled for future sale. Submerged inlets installed on 2 tanks during fiscal year 1968.
Camp Stanley, San Antonio, Tex.	Open burning discontinued on July 1, 1967, and sanitary landfill established.
Fort Wolters, Mineral Wells, Tex.	1 paper pulper installed March 1968.
Arlington Hall Station, Arlington, Va.	Residual fuel oil used since July 1, 1967, contains 2-percent sulfur maximum.
Fort Belvoir, Mount Vernon, Va.	Do.
Cameron Station, Alexandria, Va.	Do.
Fort Lee, Fort Lee, Va.	2 fuel conversions (coal to oil) were accomplished. Design completed for proposed conversion to gas with oil standby.

APPENDIX C—Continued

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968—Continued

Agency	Installation	Actions
Department of Defense—Continued		
Army—Continued		
	Fort Myer, Arlington, Va	Residual fuel oil used since July 1, 1967, contains 2-percent sulfur maximum.
	Vint Hill Farms Station, Warrenton, Va	Replaced the 3 classified waste incinerators with 1 Smokatrol unit and 6 gas afterburners.
	Fort Lewis, Tacoma, Wash	250 worn-out coal-fired furnaces replaced with oil-fired units in fiscal year 1968.
	Yakima Firing Center, Yakima, Wash	Open burning discontinued and sanitary landfill established in fiscal year 1968.
	Holston Army ammunition plant, Sullivan and Hawkins Counties, Tenn.	Engineering study, 90 percent complete, for control of particulates from 13 boilers in coal-fired heating plants.
	Volunteer Army ammunition plant, Chattanooga, Tenn.	Pending modernization of this old plant, a variety of emission reduction devices are being installed, requested, or studied.
Corps of Engineers	New York Harbor drift removal project, New York district office, New York, N.Y.	Design complete contract let and construction complete for developing the area; 3 contracts let for long-lead construction (fans, motors, hoists, transformers); contract for general construction of incinerator proper now out for bids.
	Derrick boat "Tonawanda," Cleveland, Ohio (home port).	New burners installed permitting use of No. 2 distillate fuel in lieu of No. 6 previously used.
Navy	Naval Air Station, Alameda, Alameda, Calif	Submerged inlets for motor gasoline storage tanks. June 30, 1968, expected completion date.
	Naval Weapons Station, Concord, Concord, Calif	Submerged inlets for motor gasoline storage tank. June 30, 1968, expected completion date.
	Naval Air Station, Lemoore, Lemoore, Calif	Open burning discontinued and on-station sanitary landfill established May 1967. Submerged inlets for motor gasoline tanks completed January 1968.
	Naval Station, Long Beach, Long Beach, Calif	Paper pulper installed November 1967.
	Naval Air Station, Moffett Field, Sunnyvale, Calif	Incineration of garbage discontinued. Hauled away by contract. Submerged inlets on motor gasoline storage tanks by June 1968.
	Naval Postgraduate School, Monterey, Monterey, Calif.	Open burning discontinued. Now using off-station landfill. Submerged inlets on motor gasoline storage tanks in June 1968.
	Naval Hospital, Oakland, Oakland, Calif	Submerged inlets on motor gasoline storage tanks to be completed by June 30, 1968.
	Naval Supply Center, Oakland, Oakland, Calif	Firebrick and grate completed March 1968. Submerged inlets on motor gasoline storage tanks to be completed by June 30, 1968.
	Naval Facility, Point Sur, Big Sur, Calif	Submerged inlets on motor gasoline storage tanks to be completed by June 30, 1968.
	Fleet Training Center, Naval Station, San Diego, Calif	Contract for preparation of 30 percent final plans and specifications will be let before June 30, 1968. Architect-engineer selected.
	San Francisco Bay Naval Shipyard, Hunter Point Site, San Francisco, Calif.	Boiler plants in buildings 521 and 203 converted to interruptible natural gas in May and October 1967. Submerged inlets on motor gasoline storage tanks to be completed by June 30, 1968.
	San Francisco Bay Naval Shipyard, Mare Island Site, Vallejo, Calif.	Powerplant, building 121 converted to natural gas, June 25, 1967. Submerged inlets on motor gasoline tanks to be completed by June 30, 1968.
	Naval Communication Station, Stockton, Calif	Submerged inlets on motor gasoline storage tanks to be completed June 30, 1968.
	Naval Station, Treasure Island, San Francisco, Calif	Smoke elimination facility contract awarded Jan. 19, 1968. Boiler contract awarded in April 1968. Submerged inlets on motor gasoline tanks to be completed by June 30, 1968.
	Naval Research Laboratory, Washington, D.C	Smoke detectors ordered for installation in summer of 1968.
	Naval Air Station, Key West, Key West, Fla	In-house study of refuse disposal practice completed.
	Naval Station, Key West, Key West, Fla	In-house study of refuse disposal in Key West area completed. (Central incinerator for all area naval activities recommended.)

Marine Corps Supply Center, Albany, Albany, Ga.....	Engineering study complete. (Recommends sanitary landfill to replace 2 open-burning dumps.)
Naval Air Station, Barber's Point, Barber's Point, Honolulu, Hawaii.	Final plans and specifications being prepared for sanitary landfill.
Naval Ordnance Station, Forest Park, Ill.....	Fuel procured since Nov. 1, 1967, has contained a maximum of 1 percent sulfur.
Naval Air Station, Glenview, Ill.....	Do.
Navy Public Works Center, Great Lakes, Great Lakes, Ill.	Contract awarded for firm gas for the main powerplant effective Nov. 1, 1968, for 55 percent of annual fuel. Contract awarded for design of control devices for main powerplant. Fuel used since Nov. 1, 1967, has had a limit of 1 percent sulfur.
Naval Training Center, Great Lakes, Great Lakes, Ill..	Project cost estimate completed for firefighting school smoke elimination facility.
Public Works Center, Guam, Orote Point, Guam.....	Plans completed for a sanitary landfill.
U.S. Naval Academy, Annapolis, Md.....	New heating plant under construction. Estimated completion date, November 1968.
Naval Research Laboratory, Chesapeake Beach, Md....	Smoke detectors ordered.
Naval Ordnance Laboratory, Silver Spring, Md.....	Design project underway (to control incinerator smoke).
Naval Shipyard, Boston, Boston, Mass.....	Project cost estimate completed Aug. 15, 1967, for boiler smoke control and refuse disposal.
Naval Auxiliary Air Station, Fallon, Nev.....	Open-burning discontinued; contract refuse hauling to on-station landfill operated by Seabees. Submerged inlets on motor gasoline storage tanks to be completed by June 30, 1968.
Naval Ammunition Depot, Hawthorne, Hawthorne, Nev.	Submerged inlets on motor gasoline storage tanks to be completed June 30, 1968.
Goldsborough Housing (part of Supply Center) Bayonne, N.J.	Design completed fiscal year 1968. Disestablishment anticipated June 30, 1968. Installation will be under Army.
Reserve Training Center, Clifton, N.J.....	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum.
Ammunition Depot, Earle, N.J.....	Do.
Reserve Training Center, Elizabeth, N.J.....	Do.
Reserve Training Center, Jersey City, N.J.....	Do.
IND Reserve Shipyard, Newark, N.J.....	Do.
Reserve Training Center, Freeport, N.J.....	Do.
Headquarters, 1st Marine Corps District, Garden City, N.Y.	Do.
Mitchel Manor, Federal Housing Annex of Naval Station, Brooklyn, Garden City, N.Y.	Do.
Reserve Training Center, Huntington, N.Y.....	Do.
Naval and Marine Corps Reserve Training Center, Fort Schuyler, N.Y., Bronx, New York.	Do.
Shipyard (Naval Station, Brooklyn) Brooklyn, Kings County, N.Y.	Design authorized for special project A1-68 (incinerator scrubbers).
Marine Corps Reserve Training Center, New York City, N.Y.	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum.
Naval Air Station, New York, Brooklyn, N.Y.....	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Plans and specifications completed for boiler replacement building 4-B. Project cost estimate completed for fuel conversion of 3 boilers in fiscal year 1968. MCON project will include branch gas piping to tenant activity.
Hospital, St. Albans, St. Albans, Queens County, N.Y...	Fuel used since Nov. 1, 1967, has contained 1 percent sulfur maximum. Special project with certificate of urgency approved by EASTDIV for scrubber and modifications in fiscal year 1968. Project cost estimate completed for boiler conversion in fiscal year 1968.
Reserve Training Facility, Youngstown, N.Y.....	Special project completed in fiscal year 1968, EASTDIV approval anticipated in May 1968.
Naval Air Development Center, Johnsville, Pa.....	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Negotiations underway for selecting A. & E. firm to prepare project cost estimate (smoke control).

APPENDIX C—Continued

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968—Continued

Agency	Installation	Actions
Department of Defense—Continued		
Navy—Continued		
	Naval Supply Depot, Mechanicsburg, Pa	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Fuel selection survey completed and awaiting preparation of project for funding.
	U.S. Marine Corps Supply Activity, Philadelphia, Pa	Fuel selection survey submitted to Marine Corps Supply Activity which has obtained 1 percent sulfur fuel oil since Nov. 1, 1967.
	Naval Air Engineering Center, Philadelphia, Pa	Fuel selection survey completed and awaiting funding. Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum.
	Naval Damage Control Center, Philadelphia, Pa	Engineering investigation underway to determine most feasible method of eliminating firefighting school.
	U.S. Naval Hospital, Philadelphia, Pa	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Negotiation underway for selection of A. & E. firm to prepare project cost estimate.
	Naval Shipyard, Philadelphia, Pa	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Negotiations underway for selection of A. & E. firm to prepare project cost estimate for control of fly ash and smoke.
	Naval Supply Depot, Philadelphia, Pa	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Authorized to start plans and specifications for heating plant fuel conversion.
	Naval Air Station, Willow Grove, Willow Grove, Pa	Fuel procured since Nov. 1, 1967, has contained 1 percent sulfur maximum. Project for new boilers using low sulfur fuel approved.
	U.S. Naval Station, Roosevelt Roads, Ceiba, Humacao, P.R.	Construction underway to install emission control valves and filters in exhaust fans, June 1968 expected completion date.
	U.S. Marine Corps, Camp Garcia detachment, Isabel II-Vieques, P.R.	Sanitary landfill implemented.
	Fleet Training Center, Newport, Newport, R.I	Project cost estimate completed Aug. 4, 1967 (smoke control at fire fighting school).
	Public Works Center, Newport, Newport, R.I	Project cost estimate for incinerator completed Aug. 15, 1967. Project cost estimate for fly ash collectors completed June 2, 1967.
	Naval Shipyard, Charleston, Charleston, S.C	Open burning discontinued and refuse disposed in sanitary landfill. A. & E. working on program cost estimate for dust collector.
	Naval Supply Center, Craney Island, Norfolk, Va	Installation of smoke recorders and alarms on heating plant to be completed by June 1968. A. & E. study underway regarding waste oil disposal problem. Exploring refuse disposal by contract.
	Naval Public Works Center, Norfolk, Va	Preliminary design complete for particulate control devices for waste heat plant. Smoke detectors being designed for buildings P-1 and SU-1.
	Naval Supply Center, Norfolk, Va	Completed installation of vacuum pressure relief valve on fuel tank September 1967.
	Naval Air Station, Oceana, Virginia Beach, Va	Smoke detectors for housing area heating plant to be installed before June 30, 1968.
	Naval Ammunition Depot, St. Juliens Creek, Portsmouth, Va.	Smoke detectors, recorders, and alarms have been installed.
	Naval Hospital, Portsmouth, Va	Smoke detectors and alarms installed in April 1968.
	Norfolk Naval Shipyard, Portsmouth, Va	Smoke detectors installed at Stanley Courts and building 174 heating plant.
Air Force	Perrin Air Force Base, Sherman, Tex	Open burning eliminated with landfill. When available land is exhausted, then refuse hauling contract will be prepared.
	Lackland Air Force Base, San Antonio, Tex	Have requested shredder-pulper to replace classified paper incinerator.
	Elmendorf Air Force Base, Anchorage, Alaska	Contracted January 1968 to convert from use of coal to natural gas. Expect completion by October 1968.

Williams Air Force Base, Chandler, Ariz.	Improvements in auto maintenance shop scheduled for fiscal year 1969. Submerged inlets on 3 50,000-gallon tanks.
McClellan Air Force Base, Sacramento, Calif.	Waste lumber disposal contract expected to be completed by June 1968.
Vandenberg Air Force Base, Santa Barbara County, Calif.	Vapor recovery valves on 4 underground fuel storage tanks.
Lowry Air Force Base, Denver, Colo.	Dustless ash handling equipment installed at heating plant during 3d quarter fiscal year 1968. Refuse disposal accomplished by sanitary landfill operation.
Robins Air Force Base, Warner Robins, Ga.	Building 230 connected to central heating plant, thereby eliminating 1 furnace problem. Open burning of scrap lumber temporarily terminated by salvage and landfill operation. Available land is limited so incinerator planned for fiscal year 1972.
Belleville Air Force Station, Belleville, Ill.	Remedial action not required. Phaseout scheduled for July 1968.
Chanute Air Force Base, Rantoul, Ill.	Open burning discontinued and sanitary landfill established July 1967.
Henna City Air Force Station, Henna City, Ill.	Remedial action not needed; phaseout scheduled for July 1968.
Sioux City Airbase, Sioux City, Iowa	Remedial action not required. Facilities being turned over to ANG and Sioux City effective September 1968.
Snow Mountain Air Force Station, Fort Knox, Ky.	Cyclone separator no longer needed. Phaseout scheduled for July 1968.
Barksdale Air Force Base, Bossier City, La.	Classified waste disintegrator installed. Construction scheduled to start before Dec. 31, 1968, on nonpollutant waste disposal system for a new composite medical facility. Design underway.
Andrews Air Force Base, Camp Springs, Md.	Contract for off-base refuse disposal eliminates need for incinerator. Design underway to convert boilers in building 1515 to oil.
L. G. Hanscom Field, P.I.N. 1949, Bedford, Mass.	Smoke detection and recorder system accomplished in December 1967.
Westover Air Force Base, Chicopee, Mass.	Open burning eliminated with sanitary landfill. Close monitoring of heat plant operation.
Calumet Air Force Base, Calumet, Mich.	A. & E. design underway for plant expansion and fuel conversion.
Port Austin Air Force Station, 80 miles southeast of Saginaw, Mich.	Fuel conversion to natural gas included in project to enlarge plant. Expected completion date September 1968.
Selfridge Air Force Base, Mount Clemens, Mich.	Design in progress for fuel conversion to natural gas to be effected in early 1969.
Keesler Air Force Base, Biloxi, Miss.	Installation of submerged inlet lines in 500-gal. gasoline storage tanks. Completed November 1967.
Aeronautical Chart and Information Center, St. Louis, Mo.	Design completed and construction contract awarded in April 1968 for combination shredder-incinerator. Facility expected to be in operation by September 1968.
Kirksville Air Force Station, Kirksville, Mo.	Phaseout scheduled September 1968.
Omaha Air Force Station, Omaha, Nebr.	Do.
McGuire Air Force Base, Burlington County, N.J.	Low sulfur No. 4 fuel oil purchased for building 33-42. New boilers fired with No. 2 fuel oil installed for buildings 27-43, 27-35, 28-19, and 28-34.
National Guard Air Base, Floyd Bennett Field, N.Y.	ANG procuring low sulfur fuel oil to comply with emissions standards.
Plattsburgh Air Force Base, Plattsburgh, N.Y.	Open burning discontinued. Refuse now deposited in sanitary landfill.
Fortuna Air Force Station, Fortuna, N. Dak.	Design for new boilers completed; advertised for bid.
Grand Forks Air Force Base, Emerado, N. Dak.	Fuel conversion from coal to oil scheduled for July 1, 1968.
Minot Air Force Station, Minot, N. Dak.	Design completed and project authorized for bid advertisement. (Conversion of heating plant to gas.)
Lockbourne Air Force Base, ANG Facility, Columbus, Ohio.	Purchasing low sulfur oil to comply with emission standards.
Wright-Patterson Air Force Base, Green County, Ohio.	New incinerator installed in building 305, area B. Replaced all cones on mechanical collector for No. 2 boiler CHP 1240 (HTW). Contaminated POL to be sold rather than burned on base.
Altus Air Force Base, Altus, Okla.	Refuse disposed off base in sanitary landfill operation.
Kingsley Field, Klamath Falls, Oreg.	Submerged inlets on fuel tanks installed.
Greater Pittsburgh Airport, Pittsburgh, Pa.	Submerged inlets on fuel tanks.
Willow Grove Air Reserve Facility, Willow Grove, Pa.	No. 6 fuel oil containing 0.8 percent sulfur now being procured. Seeking oil containing 0.6 percent sulfur.

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968—Continued

Agency	Installation	Actions
Department of Defense—Continued		
Air Force—Continued		
	Carswell Air Force Base, Fort Worth, Tex.	Open burning of refuse eliminated using sanitary landfill. Commissary incinerator being used by base communications.
	Kelly Air Force Base, San Antonio, Tex.	Reclamation smelter has ceased operation.
	Hill Air Force Base, Ogden, Utah	Upgraded control equipment on classified document incinerator.
Atomic Energy Commission	National Reactor Testing Station, Bingham County, Idaho.	1 photoelectric unit with alarm system installed on steam plant at EBR II site.
	Argonne National Laboratory, Du Page County, Ill.	Requested funds to convert plant to natural gas. Funds denied by Joint Committee on Atomic Energy.
	Burlington plant, Des Moines, Iowa	Contract for engineering and design let on May 1, 1968, to convert steam plant from coal to natural gas and standby fuel oil. To be completed by October 1969.
	Paducah Gaseous Diffusion Plant, Paducah, Ky.	Work started on rebuilding electrostatic precipitators on steam plant C-600.
	Bendix plant, Kansas City, Mo.	Equipment ordered to install gas afterburner and flue gas washer with stack damper in classified waste destructor in April 1969. Completion scheduled August 1969.
	Brookhaven National Laboratory, Suffolk County, N.Y.	Requested funds to convert steam plant to natural gas. Request denied by Joint Committee on Atomic Energy.
	Knolls Atomic Power Laboratory, Schenectady County, N.Y.	Changed fuel oil contract to less than 2 percent sulfur oil. Installed submerged filling inlet on 10,000-gal. storage tank. Currently establishing offsite disposal of wastes to replace open burning.
	Oak Ridge Operations Feed Materials Production Center, Fernald, Ohio.	Smoke density recorders installed in 3 of 4 stacks. Studies of electrostatic precipitator operation underway to determine compliance with Executive Order 11282.
	Oak Ridge Operations Office, Portsmouth Area Gaseous Diffusion Plant, Portsmouth, Ohio.	Stack sampling and other studies involving fuels still underway to evaluate economics of various remedial measures including electrostatic precipitation, smoke density recorders, and fly ash equipment.
	Savannah River Operations Office, Savannah River Plant, Aiken and Barnwell Counties, S.C.	Sanitary landfill being developed to eliminate open burning. Study regarding need for electrostatic precipitators in progress.
	Oak Ridge National Laboratory, Oak Ridge, Tenn.	Vapor recovery and control system installed to control gasoline vapor loss.
	Oak Ridge Operations, Oak Ridge Gaseous Diffusion Plant, Oak Ridge, Tenn.	Funds budgeted for installation of smoke density recorders. Steam plant being studied regarding need for electrostatic precipitators and smoke density recorders.
	Oak Ridge Operations, Oak Ridge Steam Plant, Building 1916-T-2A, Oak Ridge, Tenn.	Study underway to determine feasibility of installing gas-fired boilers to eliminate smoke problem in residential area.
	Pantex plant, Amarillo, Tex.	Sanitary landfill operation installed to eliminate open burning of 3.6 tons of refuse per day.
	Richland Operations Office, Hanford Reservation, Adams, Benton, Grant, and Franklin Counties, Wash.	17 smoke density monitors have been procured for use of this plant.
General Services Administration	Federal Center Building 47, Denver, Colo.	Fuel conversion construction contract awarded in April 1968. Completion scheduled for Nov. 15, 1968. Converting from coal to gas and No. 2 fuel oil.
	Englewood Postal Station, Chicago, Ill.	Fuel conversion project out on bid. Coal to gas heating plant.
	Post Office and Courthouse, Albany, N.Y.	Funds requested for conversion to gas and No. 2 oil. Design completed.
	Bronx Central Station Post Office, Bronx, N.Y.	Project for conversion to No. 2 oil underway.
	Federal Office Building, 26th St. and 3d Ave., Brooklyn, N.Y.	Conversion of boilers to gas and No. 2 fuel oil underway. Completion date, Oct. 1, 1968.
	Federal Office Building, 35 Ryerson St., Brooklyn, N.Y.	Do.
	Post Office, Flushing, N.Y.	Do.
	Post Office, Jamaica, N.Y.	Do.

	Madison Square Post Office, New York, N.Y.	Do.
	Federal Office Building, 641 Washington St., New York, N.Y.	Do.
	Post office, Rochester, N.Y.	Conversion of boilers to gas and No. 2 fuel oil initiated.
	North Philadelphia Postal Station, Philadelphia, Pa.	Conversion of boiler from No. 4 to No. 2 oil completed.
	5000 Wissahickon Ave., Philadelphia, Pa.	Conversion of boiler to gas and No. 2 fuel oil underway.
Department of Commerce	National Bureau of Standards, Gaithersburg, Md.	Contract has been let for conversion of heating plant to gas and standby fuel oil.
	Hoboken terminal, Hoboken, N.J.	Property is under lease to Port of New York Authority. Authority has budgeted to convert to No. 2 fuel oil in summer of 1968.
	U.S. Merchant Marine Academy, Kings Point, Long Island, N.Y.	Lower sulfur fuel oil now being used. A contract has been let to study the feasibility of using a combination gas-oil fired high-pressure boiler or converting to No. 2 fuel oil.
Department of Health, Education, and Welfare: Public Health Service.	Indian hospital, Phoenix, Ariz.	Multiple chamber incinerator has been installed replacing single chamber unit.
	Outpatient clinic, Chicago, Ill.	Converted to low sulfur No. 6 oil.
	PHS hospital, Lexington, Ky.	Open burning discontinued and sanitary landfill operating.
	Northeastern Radiological Health Laboratory, Winchester, Mass.	Bids on market to obtain lower sulfur fuel oil.
	PHS hospital, Boston, Mass.	Do.
	PHS hospital, Staten Island, N.Y.	Converted to No. 2 fuel oil. Design for eventual conversion to gas is 90 percent complete.
	Quarantine station, Staten Island, N.Y.	Converted to No. 2 fuel oil.
	Outpatient clinic, Philadelphia, Pa.	Converting to lower sulfur fuel oil.
	Northeast Marine Health Sciences Laboratory, Narragansett, R.I.	Invitation to bid is on the market for lower sulfur fuel oil.
	PHS hospital, Norfolk, Va.	Converted to No. 2 fuel oil.
	St. Elizabeth's Hospital, Washington, D.C.	Contracts awarded for smoke meters on boilers, installation of afterburner, barometric damper, overfire ventilation, and burners in main incinerator.
Department of Transportation	Gloucester Coast Guard Base, Gloucester City, N.J.	Heating system converted from No. 5 residual fuel oil to No. 2 distillate oil.
	Coast Guard Training Center, Cape May, N.J.	Open burning of refuse has been discontinued. Refuse now compacted, collected, and disposed of by refuse service.
	New York Coast Guard Base, Governors Island, N.Y.	Partial conversion from residual fuel oil to No. 2 distillate fuel oil. Will be completed when funds are available.
	Elizabeth City Coast Guard Air Base, Elizabeth City, N.C.	Open burning of waste discontinued. Use of compactors and public disposal facilities accomplished.
Department of the Interior: Bureau of Indian Affairs	Mt. Edgecumbe Boarding School, Sitka, Alaska	Incinerator out on bid to eliminate open burning. Feasibility study in progress to determine modifications of heating plant.
	Chinle Agency Headquarters, Chinle, Ariz.	Stack sampling to be done to check emissions from No. 5 fuel oil.
	Hopi Indian Agency Headquarters, Keams Canyon, Ariz.	Preliminary investigation for heating plant modification to include air pollution abatement equipment has been made. An incinerator is being considered.
	Standing Rock Boarding School, Fort Yates, N. Dak.	Heating plant is being converted to No. 2 fuel oil.
	Seneca Indian School, Wyandotte, Okla.	Boilers have been replaced with liquefied petroleum gas fired units for each building. Coal fired boilers are abandoned.
	Oglala Community School, Pine Ridge, S. Dak.	Now converting centralized heating plant to No. 2 fuel oil.
	Kyle Day School, Pine Ridge, S. Dak.	Will be converted to No. 2 fuel oil for the heating plant.
	Pierre School, Pierre, S. Dak.	Now converting to No. 2 fuel oil for the heating plant.
	Intermountain School, Brigham City, Utah.	Scheduled to convert from coal to natural gas in fiscal year 1968.
	National Park Service, Grand Canyon National Park, Grand Canyon, Ariz.	Incinerators programed for 1971 and 1974 fiscal year for Desert View, North Rim, and South Rim.
Bureau of Sport Fisheries and Wildlife	Crab Orchard NWR, Carterville, Ill.	Parties operating 9 of 13 locations under lease with Bureau of Sport Fisheries and Wildlife, have been notified to comply with Executive Order 11282. 4 other installations are to use No. 2 fuel oil or gas. Open burning has been eliminated and a sanitary landfill installed.

APPENDIX C—Continued

ANNUAL REPORT OF PROGRESS BY INSTALLATION DURING FISCAL YEAR 1968—Continued

Agency	Installation	Actions
Smithsonian Institution	National Zoological Park, Washington, D.C.	Planning funds made available to GSA for heating study preliminary to phasing-out coal plant and conversion to gas. Improvements made in stack gas washer on incinerator. Plans for all-weather operation of this scrubber being drawn.
Department of Justice: Bureau of Prisons	Federal Correctional Institution, Lompoc, Calif.	Engineering study planned for waste disposal practices.
	Southwest Regional Office, San Pedro (Terminal Island), Calif.	Converted from high sulfur fuel oil to No. 2 fuel oil.
	Federal Correctional Institution, Terminal Island, Calif.	Engineering study planned.
	Federal Youth Center, Englewood, Colo.	Engineering study planned for waste disposal practices.
	Federal Correctional Institution, Danbury, Conn.	Engineering study to be conducted concerning refuse disposal practices.
	Federal Correctional Institution, Tallahassee, Fla.	Engineering study planned concerning refuse disposal practices.
	U.S. Penitentiary, Marion, Ill.	Do.
	U.S. Penitentiary, Terre Haute, Ind.	Do.
	U.S. Penitentiary, Leavenworth, Kans.	Engineering study underway. Funds for 2 incinerators to be requested in fiscal year 1970 budget.
	Federal Youth Center, Ashland, Ky.	Engineering study planned concerning waste disposal practices.
	Federal Correctional Institution, Sandstone, Minn.	Do.
	Medical Center for Federal Prisoners, Springfield, Mo.	Do.
	U.S. Penitentiary, Lewisburg, Pa.	Do.
	Federal Correctional Institution, La Tuna, Tex.	Engineering survey planned concerning refuse disposal practices.
	Federal Correctional Institution, Seagoville, Tex.	Do.
	Federal Correctional Institution, Texarkana, Tex.	Do.
	Federal Reformatory, Petersburg, Va.	Engineering study to be conducted concerning refuse disposal practices, excessive smoking from boiler plant, need for new boilers which will be gas-fired or coal with suitable control equipment.
	U.S. Penitentiary, McNeil Island, Steilacoom, Wash.	Engineering study of waste disposal to be made.
	Federal Reformatory for Women, Alderson, W. Va.	Engineering study to be made on boiler plant and refuse disposal practices.
	National Training School for Boys, Morgantown, W. Va.	New facility. Engineering study planned for refuse disposal.
National Aeronautics and Space Administration	Michoud Assembly Facility, New Orleans, La.	Funds requested for design in fiscal year 1969. Scrubbers, filters, and incinerators needed for unspecified operations.
	Goddard Space Flight Center, Greenbelt, Md.	Design for gas conversion of boiler plant has been completed.
	Langley Research Center, Hampton, Va.	Study of heating plant completed. No remedial action required on that plant.
Post Office Department	Post office, Fort Wayne, Ind.	Converted heating plant to burn natural gas.
	See list of installations [1]	Trash removal contracts were instituted to eliminate open burning or faulty incinerator practices on premises of Post Office installations. The contracts specify that ultimate disposal of materials removed must comply with local air pollution control regulations.
Tennessee Valley Authority	National Fertilizer Development Center, Muscle Shoals, Ala.	Improvements reported affect the phosphate complex, ammonia complex, nitric acid complex, diammonium phosphate complex, nitrogen fertilizer complex and also reflect the establishment of a digital recording meteorological station as part of an air monitoring network. Specific improvements include reduction in dusts, fluorides, phosphorus oxides, ammonia, acids, and oxides of nitrogen. Further reduction of dusts and fluorides are scheduled for the current year.

	Colbert Steamplant, Colbert, Ala.	Efforts are being made to up-grade the efficiency of electrostatic precipitators at this plant. Ammonia injection for conditioning flue gas was unsuccessful.
	Widows Creek Steamplant, Stevenson, Ala.	Ammonia injection systems to condition flue gas at units 7 and 8 were installed and resulted in improved efficiency of electrostatic precipitators. Work being continued toward further improvement.
	Shawnee Steamplant, Paducah, Ky.	Contract awarded for design and construction of 10 electrostatic precipitators. Tentative installation scheduled during outages occurring between August 1968 and December 1969.
	Gallatin Steamplant, Gallatin, Tenn.	Contract awarded for design and construction of electrostatic precipitators. Installation scheduled during March-November 1969.
	Power Building, Chattanooga, Tenn.	Coal-fired boiler has been replaced with electric heating equipment.
Veterans' Administration	VA Hospital, Grand Junction, Colo.	Construction to convert boilers to gas-fired units underway.
	VA Hospital, West Haven, Conn.	Do.
	VA Center, Dublin, Ga.	Construction for conversion of boilers from coal to gas underway.
	VA Center, Des Moines, Iowa	Boiler modernization project completed. New boilers are gas-fired.
	VA Hospital, Knoxville, Iowa	Construction for conversion of boilers from coal to gas underway.
	VA Hospital, Louisville, Ky.	Do.
	VA Hospital, Castle Point, N.Y.	Discontinued incineration, disposing of waste by contract collection.
	VA Hospital, Montrose, N.Y.	Construction for conversion of boilers to gas-fired units underway.
	VA Hospital, Durham, N.C.	Design for conversion of boiler from coal to gas completed.
	VA Hospital, Fayetteville, N.C.	Construction for conversion of boilers from coal to gas underway.

OPERATING EXPERIENCE WITH WET-DOLOMITE SCRUBBING

In September 1967, Combustion Engineering, Inc. and Union Electric Co. announced plans to install a full-scale sulfur dioxide removal system on one of the units at Union Electric's Meramec plant in St. Louis County. The system was developed by Combustion Engineering and utilizes limestone or dolomite injection into the furnace and a wet scrubber for particulate and sulfur dioxide removal. Results of laboratory tests and field tests of a pilot system at the St. Clair plant of Detroit Edison Co. were reported at the American Power Conference in April, 1967.[1]

The system was designed and installed on the Meramec No. 2 unit during the period October 1967 to June 1968 (Fig. 1). Initial operation was deferred until September 1968 to avoid the summer high-load period. The system was operated initially on natural gas beginning September 9, 1968 and initially with coal on September 19. During the period September 1968 to May 1969, the system operated on coal for 31 days.

Operation of the system has revealed problems that were not evident during initial experience with the pilot plant at Detroit Edison. It is the purpose of this paper to describe this operating experience, the modifications that have been made to the system, and the plans and expectations for the future.

Description of System

A schematic of the sulfur dioxide removal system is shown in Fig. 2. Crushed limestone is delivered to the plant by truck and unloaded into a hopper normally used for rail coal unloading. The coal conveyer system is used to transport the limestone to

the No. 2 unit coal bunker. During this operation, coal cannot be transported to the plant. The No. 2 bunker has been partitioned to separate the limestone above the "A" pulverizer from the coal above the other three pulverizers.

The boiler-turbine unit has a maximum capability of 140 Mw. This capacity can be obtained with three pulverizers when the pulverizers are in top grinding condition. Some loss in unit capacity can be expected as the pulverizers wear, since the fourth pulverizer is used for limestone.

The "A" pulverizer and exhauster system pulverizes the limestone and injects it above the coal flame from the other burners. The "A" burners have been disconnected from the burner tilt mechanism and are fixed in a 15° upward position. The electrostatic precipitators have been blanked off with one half of the blanking plates at inlet and outlet welded in place and the other half being bolted. This is done so that the bolted plates can be removed during a short outage and the generating unit operated with flue gas going through the precipitator while modifications are made to the SO_2 removal system.

A closed loop, liquid heat exchanger system is provided to extract heat from the flue gas ahead of the scrubbers and to reheat the flue gas after the scrubbers. The system is designed to reheat the flue gases 50 F for plume appearance, primarily.

Two National Dust Collector Hydro-Filter scrubbers are installed to operate in parallel (Fig. 3). Power-operated inlet and outlet dampers are provided for control to maintain a minimum gas velocity through the marble bed and for isolation of each scrubber.

Flue gas enters the scrubber beneath the marble bed and flows through the bed and out the top of the scrubber. Water sprays are located beneath the marble bed and are directed upward. The high-pressure drop through the marble bed causes the water spray to be broken up into a turbulent layer of water mist which traps the particulate matter. Water and collected particles overflow into drains which discharge below the bed. A gravity drain line from each scrubber discharges water and collected particles to the clarifier.

Solids are concentrated in the clarifier and pumped to a disposal pond. Most of the water is clarified and recycled to the scrubber.

The flue gases pass from the marble bed through a demister and the reheater and then to the induced-draft fan.

Expected Performance

Based on the pilot plant experience, Combustion Engineering has guaranteed that the air pollution control system (APCS) would perform as follows:

1. The sulfur oxides leaving the APCS are equivalent to burning a fuel containing 0.5% sulfur when sulfur in the fuel is no greater than 3.4%.

2. The particulate matter removal from the flue gas entering the APCS will be 99%.

Operating Experience

I. D. Fan Inlet

The reheater is a finned tube heat exchanger with close spaced tubes and fins. Cleaning of the heat exchanger was intended to be done by a water wash system using the scrubber spray

water. The wash system consisted of sprays located above and below the reheater. Originally it was planned that washing would be done at half load with the scrubber inlet and outlet dampers closed. The final design was worked out with on-line washing planned.

After approximately 12 hours of operation on coal, the wash system was operated to determine whether it would function properly. Some of the wash water carried over to the I.D. fans. It was observed to be leaking out of access doors in the fan inlet boxes. After a few hours, I.D. fan vibration increased. Inspection showed a heavy buildup of deposits on the fan blades with a thickness as great as 1 in. in spots. Sand blasting was required to remove the deposits.

It was apparent from this experience that moisture must be kept out of the fans. Drains were installed initially on the fan inlet boxes. These were later changed to an eductor system. Also, top reheater sprays would not be used when the scrubber was on line and botton sprays would be used carefully.

No further problems were experienced with fan blade deposits. Normally there is no moisture carryover from the reheater. Moisture has been observed coming from the inlet box drains during start-up and during single-fan operation.

Overflow Drains

Another early problem was the deposit of calcium sulfate on the overflow drain screens (Fig. 4a). These deposits formed in a short period of time (less than 24 hours) in sufficient amount to restrict the water flow and cause a high water level

in the scrubber. The screens were redesigned to increase the the size of openings and were painted with a polyurethane coating which has been found to reduce deposits (Fig. 4b). From the data obtained since making the above change, this problem seems to be solved.

Marble Bed Plugging

When operation of the system for periods longer than a few days was undertaken, the problem of plugging of the marble bed was observed. The bed would become inactive at the gas inlet end of the scrubber and this would progress until, on one occasion, more than 50% of bed area became plugged. High velocity in the active portion of the bed would cause carryover of water and solids resulting in deposits on the demister and the reheater.

Model tests of the scrubber were made by Combustion Engineering first using a water table and later using a three-dimensional air-flow model. Poor gas distribution was found as illustrated in the photograph of the water table in Fig. 5a. A series of ladder vanes, demonstrated by model tests, corrected the gas distribution problem (Fig. 5d). These were installed and the scrubber system was operated for six days without bed plugging. It would appear that this problem has been corrected, although a longer period of operation is needed to be certain.

Reheater Plugging

As previously described, the marble bed plugging caused carryover of water and solids to the demister and reheater.

As a result, the reheaters of both scrubbers became severely plugged so that the APCS was inoperable. Efforts to remove deposits by sandblasting and high pressure water-jetting were only partially successful. Due to the very close spacing of the finned tubing, sandblasting and water-jetting could not penetrate deep enough to completely clean the heaters. During a six-day period of operation with the reheater partially cleaned and scrubber bed operating properly, continued buildup of deposits on the reheater was observed despite frequent off-line water washing. Inspection of deposits on the reheaters indicated that when the scrubber bed was operating properly, dry deposits formed on the reheaters. In addition, data showed that the reheater surface could be reduced. Because of these two observations, the reheater surface in one scrubber was reduced 40% and manually-operated air soot blowers were installed and tested for 30 hours. No plugging occurred.

As of this writing, the lower half of the reheaters in both scrubbers has been removed and retractable air soot blowers are being installed. The lower half of the reheater held the heavy deposits. It is thought that the soot blowers will maintain acceptable cleanliness of the reheaters with the marble bed operating properly.

Scrubber Inlet Deposits

Possibly, the most difficult problem of all has been the buildup of deposits at the scrubber inlet. Model tests showed part of the problem as being a boundary-layer separation (Fig. 5b) which could be corrected by installation of turning

vanes in the inlet duct. After the turning vanes were installed (Fig. 5c), the deposit problem continued. This deposit builds up to the point where the inlet dampers become inoperable. Various configurations of inlet duct extension into the scrubber have been tried with some significant improvement being experienced on the most recent test run. All scrubber inlets are now being modified. However, to insure control, a half-retract soot blower is being installed in each inlet to remove deposits which may still occur.

Sulfur Dioxide Removal

Guaranteed sulfur dioxide removal efficiency has been obtained for short periods. This has required a greater use of additive than expected (130% to 140% vs 110% of stoichiometry). Spray water entering and leaving the clarifier has a pH of 9 to 10 instead of the 6 to 7 expected. Tests of slurry leaving the clarifier show a significant amount of reactive additive. It appears that a substantial portion of the limestone additive is removed below the marble bed and drains directly to the clarifier where some of it goes into solution as calcium hydroxide and is used in the scrubber for sulfur dioxide removal and some is removed with the ash and precipitated sulfates and pumped to a slurry pond.

It is now planned to recycle a portion of the clarifier underflow in order to utilize the additive more efficiently.

Particulate Removal

Tests have not been performed to determine particulate removal efficiency. However, stack appearance approximates that of an adjacent unit which has a high-efficiency electrostatic

precipitaters. Dust loading tests are planned during the next operating period.

Clarifier System

The clarifier and slurry pumping system has operated successfully with only minor problems evidenced at this time. Plugging of the pump suction has occurred a number of times due to restrictions caused by power-operated butterfly valves. These have been changed to plug valves to minimize the restriction. Solids concentrations of 20 to 30% by weight have been measured in the clarifier underflow. A short term concentration of 50% by weight was measured on one occasion.

Plume Heating System

Except for the reheater plugging previously described, the heat exchange system has operated satisfactorily. Flue gas temperature entering the reheater has typically been 120 F and has been 190 to 200 F leaving the reheater. As expected, a vapor plume exists when temperature and humidity conditions dictate. During moderate weather, a vapor plume frequently exists during night and early morning hours and disappears as ambient temperatures increase and reappears in the evening.

While plume appearance is still important and of concern, the experience with I.D. fan blade deposits suggests a compelling reason for plume reheating that was not apparent before. It is doubtful that fan blade deposits can be avoided if reheating is not provided.

Boiler Operation

Minor modifications were made to the limestone pulverizer

to minimize rejects which were quite high in early operation. A new feeder drive was installed to give better control in the 1 to 3 rpm range needed for this system.

No problems have been experienced with the furnace and convection pass of the boiler, with one exception. Buildup of deposits were found in the vicinity of steam aspirated O_2 probes which were backwashed with water. These will probably be changed to air cleaning probes. Fall out of solids increased in the air heater hopper requiring more frequent emptying of the hopper. This was particularly troublesome at half load when one scrubber was operated and gas velocities leaving the air heater were low. Some modification to the air heater hopper and to the removal system will probably be required.

Future Plans

As of this writing, plans are to start up the APCS about June 1, 1969. Work on modifications is going ahead, but construction trade labor disputes may delay the completion of this work. If delays are encountered, it may be necessary to postpone the operation of the system until fall to avoid possible forced outages of the unit during peak load periods.

It is expected that a portion of the clarifier underflow will be recycled to determine if additive loss can be reduced. A long operating period is needed to determine reliability of the system and to establish operating and maintenance costs.

Summary

Operation of the APCS has revealed problems that were not evident in the small pilot plant which was operated at one of

Detroit Edison's plants. This in itself is not surprising, since the extrapolation from a small pilot plant to a full-scale unit of the Meramec size must be done with considerable risk. Combustion Engineering and Union Electric recognized that this would be a development project and that inevitable problems would occur which would require design changes. To be candid, we should say that trouble occurred where we did not expect trouble and did not occur, as yet, where we expected it.

In the seven and one-half months since the system was first started, there have been 31 days that the system has operated on coal. A number of modifications have been made. Most of the major problems appear to have been corrected, but more operating time is needed to confirm this. The system is now out of service for further modifications and we expect to start up again in June.

The system has demonstrated that it will remove the amount of sulfur dioxide expected although complete and formal acceptance tests have not been performed. Particulate removal has not been determined. Although the system cannot be considered commercially acceptable at this time, a great deal has been learned from this development project and both Combustion Engineering and Union Electric are optimistic about the ultimate workability of the system.

An extended period of operation is planned in order to establish the reliability of the system and to determine operating and maintenance costs. After having obtained this information, we will be able to determine the applicability of the system for both existing and new large units.

JEN. DEP. EXHIBIT 12

June 7th
1965

Mr. R. H. Inman

I visited with Mr. Bacon on May 28, 1965 concerning the *#2 coal prospect near Roodhouse, Illinois* that he has brought to our attention.

Mr. Bacon has copies of all the drill logs which Pittsburg-Midway has drilled in this area plus other information he has gathered through outcrops, water wells, and a clay mining company that did some drilling and mining in this area. He also claims to have analyses from his own small strip mine. Mr. Bacon will not relinquish the drill information until he has a written agreement with us that we will take an option to purchase on his property and that we will exercise this option before we exercise any other option we may take in this field. Mr. Bacon took me over the area and it appears there is approximately 5000 acres in the immediate vicinity which is under 75′ overburden. If the strippable overburden limit is 50′ this will reduce the acreage by at least one-half. Also there may be more coal acreage adjacent to the area, but it is difficult to tell how much. I doubt if this will be over 3000 coal acres under 75′ overburden. From the information Mr. Bacon gave me the location of coal outcrops do not agree very well with that shown in ISGS Circular 311, Part 3. The coal in this area maintains a consistent 2′6″ thickness where present, but there are numerous washouts. There is a sandstone bed above the coal which according to Mr. Bacon varies from 5′ to 20′ in thickness. Mr. Bacon claims the sandstone is hardest near the outcrop, but becomes soft and friable under deeper overburden. Also in this area there is a lens of coal which is locally as much as 8′ thick and called the Roodhouse coal. Its areal extent is not known.

Ayrshire has exercised three options within this area. I don't have these plotted, but I know they are not ad-

joining and that they cover some of the better strip land in the field.

A few days before I arrived in Roodhouse Mr. Bacon spoke to a man representing Morgan Coal Company. Mr. Bacon gave Morgan the drill logs previously mentioned and it appears they are interested in this field.

Mr. Bacon would like to sell his property as soon as possible and I feel if we are going to do something here it should be done this summer. If we can work out an agreement with Mr. Bacon to obtain the information he has and use this with our own drill records I feel we can get a reliable estimate on most of this field. Preferably this should be done before we go in here.

JEN. DEP. EXHIBIT 13

June 7th
1966

Mr. R. H. Inman

ROODHOUSE FIELD

In the main body of this field there is an estimated potential of about 10,000,000 tons with an average overburden of 50′, using a 70′ maximum overburden as cut-off for the estimate. As the coal averages 2′6″ thick, this would give a maximum ratio of 32 and an average ratio of 23. Most of the property we have optioned in this area is not within this 10,000,000 ton area, therefore, we have only a limited amount of drilling to estimate from. We do not know the extent of the faults in the area and those could affect the tonnage estimates either way with the possibility of decreasing the estimate. As you know, Ayrshire has retained land in this field. Within the estimated 10,000,000 ton area they have a total of 635 acres with about 350 coal acres containing approximately 1,220,000 tons of strip coal.

There is another potential area less than 1 mile to the west across Wolf Run Creek which may contain 5,000,000 tons of strip coal with less than 70′ overburden. The drilling here is scattered and the area still needs to be proven. We do have a few options in this area which indicate the presence of a possible 5,000,000 tons.

We also have an isolated option on the Stechol property about 6 miles east and 2 miles north of the main Roodhouse Field. This area is in the bottom land of Apple Creek, but does offer the possibility of picking up additional strip coal if the bottom land is minable. The Stechol 260 acre option contained 189 acres of coal or 659,000 tons with an average ratio of 28.

The general terrain of the Roodhouse area is filled with gullies and could contain several million tons under 70′ of overburden, but would be narrow strips of contour

mining. No estimate was made of these areas, although much of the options that we had taken lie in this type of terrain.

In 1948 we drilled in an area about 5 miles to the south. The area is near the town of Wrights and offers the possibility of adding additional tonnage to the field. There is approximately 480 acres of drilled coal reserves with less than 70′ of overburden in this area. The average coal thickness is 2′6″ with a ratio of 23, giving a total drilled coal reserve of 1,670,000 tons with the possibility of gaining additional reserves on adjacent properties. This reserve is bisected by the C. B. & Q. Railroad which would require mining two separate areas.

The C. M. & O. Railroad lies about 3 miles west of the western edge of the 10,000,000 ton Roodhouse area. The C. M. & O. intersects with the C. B. & Q. about 3 miles south at Whitehall, Illinois. The Illinois River is approximately 15 miles in a straight line west of this field.

If the potential of this field is satisfactory and we intend to prospect the area further it is recommended that we keep all or a part of only 8 of the 17 options, and pick up more options in the areas offering the greatest strip potential which we are now better suited to choose.

Below is a summary of each of the tracts we have options on in the Roodhouse Field. The drilling in this field was done by John Hoskins Company.

1—Wagner, 160 acres. The minimum overburden is 60′ and the ratio is 40 cu. yds. The cost per ton would be 10¢ on 561,000 tons estimated. Earned royalty is 15¢ per ton. Recommend that this be dropped because of the high overburden.

2—L. Gilmore, 65 acres. This would be cropline mining in hollows only. Recommend we drop this.

3—K. Henneberg, 120 acres. This tract is in the estimated 5,000,000 ton area as mentioned above and should be kept. There is 100 acres of coal and 337,000 tons. The overburden is from crop to a maximum of 71′ with an average ratio of 26 and a cost per ton of 12.5¢ or an earned royalty of 15¢ per ton.

4—W. VanSicson, 195 acres. There is 170 acres of coal. The overburden is outcrop to 90′ with an average ratio of 32. The cost per ton would be 11.5¢. The lower overburden in this estimate is crop-line mining, therefore I recommend it be dropped.

5—M. Tillery, 160 acres. This is in the 10,000,000 ton area and I recommend that we keep only 40 acres. This is an isolated 40 acres from the other 120 acres in the option and contains all the coal. Cost per ton on 160 acres is 39¢, but the cost per ton on the 40 acres would be approximately 10¢ or 15¢ earned royalty. Average ratio is 20 and the overburden is 35′ to 52′. Estimated 144,000 tons.

6—P. Bell, 260 acres. Recommend that it be dropped. There are 225 acres of coal or 758,000 tons. Overburden is 40′ to 80′ with an average ratio of 31. Mostly cropline mining, but some of it is in the 5,000,000 ton area. Cost per ton is 12¢. Earned royalty is 15¢.

7—W. Gilmore, 618 acres. Recommend that this be dropped. 160 acres of coal or 557,600 tons under 70′ of overburden, but would be cropline mining. Cost per ton would be 39¢.

8—E. Spencer, 417 acres. This is divided up into several separate tracts. Recommend that it be dropped. Practically all would be cropline mining and hollows or mining of deep overburden over 70′.

9—H. Strammat, 120 acres. Recommend that it be dropped. Only 30 acres of coal or 105,000 tons. Would be cropline mining and cost per ton would be 40¢ and the average ratio is 23.

10—A. Ontousn, 80 acres. This tract is in the 5,000,000 ton area. Recommend that we keep it. There is 75 acres of coal or 253,000 tons. Cost per ton would be 11.1¢ or 15¢ earned royalty. Average ratio is 26. Overburden ranges from 30′ to 70′.

11—J. Sheppard, 172 acres. Recommend that we keep 80 acres which is in the 10,000,000 ton area. This 80 is separate from the other 92 acres in the option. There are 26 acres of coal or 91,000 tons. The cost

per ton would be 66¢ on the 172 acres, but 30.8¢ on the 80 acres. Average ratio is 15 and the overburden is from outcrop to 45′.

12—M. Townsend, 42 acres. Recommend we drop this as it will be all cropline mining.

13—L. H. Hubbard, 160 acres. This option is divided into two separate tracts. I recommend that we drop the 90 acre tract which contains only 10 acres of coal or 34,850 tons. Cost would be 90¢ per ton, however, if we plan further prospecting in this area we recommend we keep the 70 acre tract since it is lying in the 5,000,000 ton area. There is not enough drilling on this to provide an estimate at this time.

14—W. L. Allen, 40 acres. Recommend that we keep this. Contains 30 acres of coal and is located in the 10,000,000 ton area. It is estimated to be 105,000 tons with an overburden range from cropline to 44′ and the average ratio is 16. The cost per ton would be 13.3¢ or 15¢ earned royalty.

15—R. A. Smith, 202 acres. Recommend that this be dropped. 179 acres of coal would be cropline mining and the plus 70′ of overburden, however, there is 582,000 tons with an average ratio of 23. Cost per ton would be 12.2¢ or 15¢ earned royalty.

16—S. Steckel, 260 acres. Recommend that we keep this tract. It is the isolated tract in the Apple Creek bottom and contains 189 acres in less than 70′ of overburden. The estimated tons is 659,000 with an average ratio of 25. Cost per ton would be 13.8¢ or 15¢ earned royalty.

17—R. Pollack, 240 acres. Recommend that this be kept. There are 147 acres of coal or 512,000 tons. It is located in the 10,000,000 ton area. The average ratio would be 20. Overburden ranges from outcrop to 56′. The cost per ton would be 16.4¢ or 15¢ earned royalty.

It should be kept in mind however that if we do keep any of these tracts, we, under previous agreement are obligated to take the Bacon option. On the Bacon tract we had estimated 181,000 tons. The cost per ton here

would be 19¢, but if you include the Model 702 Kochring dragline, the cost per ton would be 23¢.

It should also be noted that on the list of options that should come up before the Board meeting, those listed beginning with Albert Bateman in Green County expire in September rather than August as stated on the list. If there was another Board meeting in August we still would have approximately 90 days to decide on these 8 tracts. These represent 6 of the 8 tracts that we would consider keeping if we intend to prospect this field further. The other 2 that we recommend to keep—Hanneberg is in the 5,000,000 ton area and the Kenneth Tillery which we suggest we keep only 40 acres possibly could be dropped and if anything developed we could pick these up at a future date. In the meantime this would give us approximately 90 days before the others were expired to pick up additional tracts where we feel the greatest potential lies and give us a better chance to rule on the Roodhouse Field. I had only noticed that these dates were wrong since we last talked about the Roodhouse Field.

Attached are 2 copies each of the analyses of 4 cores taken at the Roodhouse Field. Also attached is an average of these 4 analyses along with the comparison study of the No. 2 coal in other areas of Illinois.

We now have on file, Corps of Engineer maps and 15′ quadrangles of the area.

P-2003303

For thirty-eight years your Company has been engaged in a single business—mining bituminous coal by the strip or open pit method and marketing that coal in the Midwest.

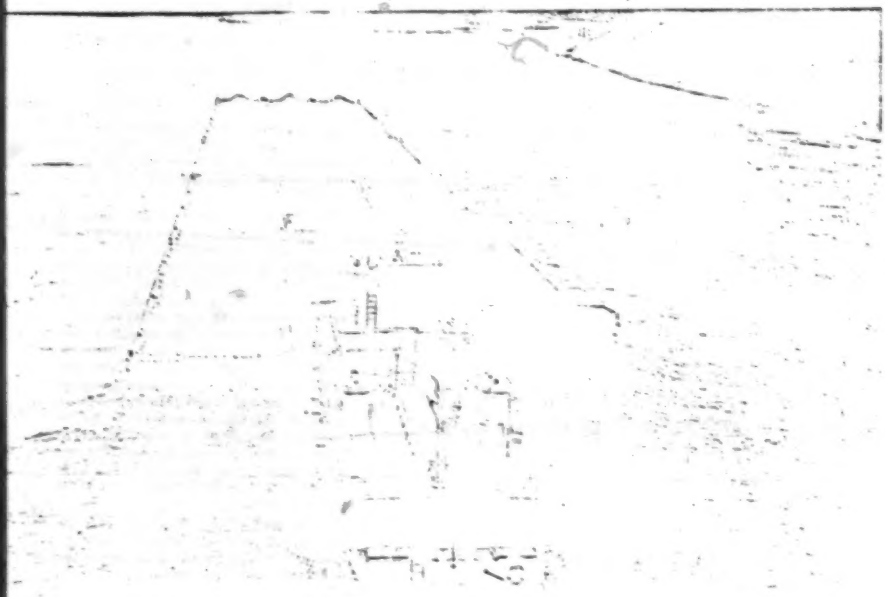
The coal seam in a strip mine must lie closer to the surface than in an underground mine. In our method of mining, the coal is uncovered by removing the dirt, rock, and shale with large earth moving machines. These machines represent a larger investment in equipment than would be necessary for a comparable operation in underground mining. Strip mining, however, has resulted in a higher output per man-day which, in the face of constantly increasing labor costs, has placed these mines in an excellent position competitively in the industry. The increase by your Company in tons produced per man-day has been two and one-half times the gain by all bituminous mines in the United States in the last ten years.

The progress of your Company over the past several years may be more clearly understood by noting some of its specific developments and improvements.

The use of this excavator in a pit with a shovel makes possible the recovery of coal with overburdens up to 100 feet. Three or four times as much material is moved in a month with "wheels" as was moved with the draglines they replaced. The use of a "wheel" with a shovel permits the shovel to operate at its greatest efficiency. Drilling and blasting from the ledge created by a "wheel" on the digging side of the pit reduces those costs because the material moved to form the ledge does not have to be drilled or blasted. The much wider pits made possible with the use of wheel excavators has improved the operating performance of the entire pit including the coal loading shovels and truck haulage units. The "wheel" and a shovel working together can economically strip coal which could not have been mined before at a profit.

HAULING COAL In order to reduce the cost of transporting coal from the pit to the preparation plant, we are using larger truck haulage units than formerly. We have recently acquired our first fifty-ton trucks which will haul about 50% more than the units they replaced.

PREPARATION OF COAL FOR MARKET Modern industrialization makes great demands on the washing, sizing, and quality preparation of coals. All of our mines are equipped with preparation plants designed to meet these demands. Our two most recently constructed plants are of the new "heavy media" design. These "heavy media" plants provide a finer,



DRILLING At some mines rock present in the ground overlying the coal adds a problem to the removal of the overburden—the material above the coal. The rock must be drilled and blasted before it can be moved.

We have met this problem by designing and developing a new rotary type drill. This drill, using compressed air rather than water to bring up the drill cuttings, is completely self-propelled and has a single drill stem long enough to permit the drilling of a complete hole. The footage drilled per man-hour has doubled in the last three years with the use of this drill.

BLASTING ROCK When the drilling is completed, the holes are filled with explosives which, when detonated, break the rock material to a size that can be moved. During the period of a year we use several million pounds of explosive for this purpose.

The cost of this operation was substantially reduced when we inaugurated the use of a new explosive a year ago. After years of research we discovered this compound, called Unimite, which had the qualities of strength, compactness, and safety so valuable for our needs. We are making this explosive from its basic ingredients on our mine property. Unimite not only gives us a cost savings per pound but permits drilling fewer holes—over 50% greater recovery per hole drilled.

STRIPPING Stripping is essentially a tremendous earth moving process and is performed by developing a long ditch or pit down to the coal, moving the material off the coal along one side of the pit and depositing it on the other side. By continuing this operation, always working in the same general direction, the open pit is gradually moved along exposing the coal which can then be removed. In stripping overburden, which is usually the most costly operation at a strip mine, your Company has made particularly important progress.

The conventional machinery used for this work has been a shovel or a dragline in pits of about 50 feet or less. In pits higher than 50 or 60 feet a dragline may be able to operate alone but usually a shovel and a dragline are necessary. These shovels are highly efficient machines but experience has shown that draglines usually result in high cost operations. As low overburden stripping reserves become increasingly difficult to find, this cost problem has become more important.

Your Company's answer to higher overburdens and a faster and cheaper method of moving dirt is the Kolbe wheel excavator and our three principal mines are equipped with these machines. The wheel excavator was conceived by your Company's president, Mr. Frank F. Kolbe, and developed by him and our engineers.

Although the machine itself is very complicated, the principle of the wheel excavator is easily understood. Material is taken off one side of the pit by a revolving wheel and moved across the pit continuously by a belt conveyor system.

more uniform control over preparation than other types and thus produce a better product. This is accomplished with less waste refuse and consequently at cost savings.

WATER TRANSPORTATION Transportation to the consumer is a major part of the delivered price of coal. Water movement of commodities, when practical, is considerably less expensive than other means of transportation. United Electric recognized the importance of low cost transportation of our coal and consequently were pioneers in the development of water facilities for coal in our area.

All of our principal mines are located along the Illinois or Mississippi rivers. About 50% of the coal from these mines is moved by water. We have recently invested in a barge line to further expand the markets for our coal through water transportation. We are also developing the first all-water movement of coal from Illinois mines to ports on both banks of Lake Michigan which will provide an additional outlet for our coal during the summer months. This is being accomplished by means of a barge to boat transfer operation.

These developments and improvements have been pursued to strengthen our position in the coal industry and in the overall industry of energy and fuel.

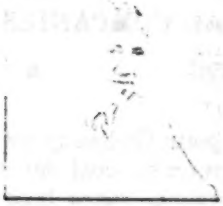
Kolbe Deposition Exhibit 4
The United Electric Coal Companies - 1958 Annual Report



To the Stockholders of The United Electric Coal Companies

THE PRESIDENT'S LETTER

During the past year American business and industry felt the impact of a general slackening in economic activity. United Electric's production in this period was off 7 per cent.

National production of coal during our fiscal year was about 420 million tons – 80 million tons less than during the previous year. The steel industry and export markets took 50 million tons less than in 1957 and this represents 63 per cent of the total decrease for the year. We serve neither of these two markets, however, and consequently that reduced demand resulted in no loss of business to your Company. Our decrease in output was limited to the effects of lower industrial production and resulting reduced power requirements by industry. Power requirements for residential use increased.

The expanding electric utility industry makes the outlook for coal very encouraging. Utilities are now the leading consumer of bituminous coal and prospects are bright for a continued strong growth in coal requirements for the generation of electric power. Utilities have about doubled their consumption of coal from 1949 to 1957. The Federal Power Commission has recently predicted that energy requirements for all utilities in the United States will double from the present time to 1970 and almost triple by 1980. The gain forecast for our area is slightly more than this.

KOLBE DEPOSITION EXHIBIT 7

THE UNITED ELECTRIC COAL COMPANIES

1961 Annual Report

* * * *

COAL DEPOSITS/At the year end your Company owned or controlled 122 million tons of recoverable coal deposits. This tonnage is greater than in previous years because, for the first time, we are including underground coal. The total amount that can be mined by the strip method is 86 million tons and 36 million tons are suitable for underground mining. We have confidence in the future of coal and we continue to add to our holdings when worth-while deposits are offered to us.

* * * *

This growth is important to the coal industry and is particularly significant for our Company. Last year one half of our total output was sold to utilities. Numerous large utility plants are under construction, or are being planned, in our area and we will benefit from that expansion.

It has been our objective to develop electric utility business to take advantage of the inherent stability and growth in that industry. This type of business enables us to invest in capital expansion with a minimum risk of excess productive capacity. In supplying this expanding demand for our product we avoid the serious price fluctuations which occur in widely varying and cyclical markets.

While oil for utility and industrial consumers is not a cause for concern in our market area, as our prices are below those for oil, "dump" gas does pose a serious problem for our Company. It is difficult to compete with the by-product price of this gas dumped on the market during the summer months. The Company subscribes to the view that it is a waste of a valuable natural resource by the gas industry to sell below cost to industrial consumers during the summer period and has favored legislation to prohibit such sales. We also feel it is inconsistent to have existing gas reserves dissipated in this manner when our Federal Government is encouraging with favorable tax laws the exploration for new reserves.

I take this occasion to express my sincere thanks to all the employes of United Electric for their continuing and loyal efforts which are always so important in determining the success of the Company.

Respectfully submitted,

Frank F. Kolbe

President

KOLBE DEPOSITION EXHIBIT 12

February 27, 1957

Mr. W. B. Hillery
Greenwood Cut Stone Co.
Box 54
Greenwood, Arkansas

Dear Mr. Hillery:

We have gone over the maps and drill records of the Central Coal and Coke property in Sebastian County, Arkansas. I think that since it is a completely different type of market from that in which we are now engaged, it is too far out of our line for us to become interested at the present time.

Thank you, though, for bringing it to our attention, as it apparently has considerable merit.

It was nice to hear from you and to see that you are keeping yourself busy. We have been doing well, but at the moment the coal demand has been softening somewhat.

Very sincerely yours,
President

Mr. T. H. Latimer

KOLBE DEPOSITION EXHIBIT 13

February 18th
1957

Mr. F. F. Kolbe:

I have gone over the maps and drill records of the Central Coal & Coke property in Sebastian County, Arkansas. This was submitted through W. B. Hillery.

This is but a few miles northeast of our Pine Mountain, Oklahoma field, and lies partly under Potoau Mountain, which you may remember seeing just east of Potoau, and partly under Sugarloaf Mountain. It is on the Rock Island Railroad, adjoining the town of Hartford, Arkansas.

This coal outcrops near the base of the mountain, apparently at an altitude of about 750 feet. There is apparently a small amount of stripping around the crop, but the coal dips under the mountain, and then flattens out. The drill records have no elevations on them, so I cannot determine the pitch, said to be 10%.

Analysis of the coal (Hartshorne seam) is given below.

Moisture	.81%
Volatile Matter	18.50
Fixed Carbon	74.48
Ash	6.31
Sulphur	.79
BTU	14,691

According to Central Coal and Coke, the thickness is about four foot, and the roof is good.

The drill records do not quite bear out the four foot thickness, and quite a number of check holes should be put down. These would run from 25 feet to perhaps 1300 feet in depth.

They own over 12,000 acres of mineral rights, and almost as much surface, and show over 85,000,000 tons in place.

This is an excellent grade of coal, and apparently is suitable for the type of coke the Western steel mills need badly, it is strictly an underground mining proposition, and I do not know how well it will lend itself to mechani-

(1) Assets estimated as of 12-31-57

(2) Income does not include special credit of $920,068—principally gain on sale of land

(3) Income for year ended 1-31-58

The 500 largest industrial corporations in the United States earned 9.2% on their assets in 1955, 6.2% in 1956 and 7.8% in 1957. About one-fourth of these 500 corporations earned 10% or more on their assets.

As indicated on the attached schedule Ayrshire Collieries, Old Ben, Peabody, and United Electric earned as a group 6.5% on assets in 1957. If sales realization had been about 15¢ a ton higher, which would have increased profit after taxes 10¢ a ton, those companies would have earned 9% on assets—about the average of the 500 largest corporations. If it is assumed that the four coal companies should earn 10% on assets, the before tax income would have to be increased by 35¢ to 40¢ a ton by either higher realization or lower costs.

Some of the coal companies have substantial interest charges on long term debt. In order to make all companies comparable this is eliminated in the last column and an appropriate adjustment is made in taxes. If it is assumed that the above four coal companies should earn before interest charges but after taxes an amount equal to 10% of assets, the 1957 income before taxes would have to be increased by about 25¢ a ton.

KOLBE DEPOSITION EXHIBIT 17

November 21st
1957

Mr. F. F. Kolbe

RE: Number 5 Coal in North Canton Field
(Specifically, an area 1½ miles north of Canton, west to Fiatt, north to Fairview, thence northeast to Farmington, south to 1½ miles north of Canton.)

Figures are based on information received from the Illinois State Geological Survey.

This area has been very sparsely drilled and there is a possibility of some faults in this area which are unknown in extent. However, with what information is available, it appears the coal dips 60 feet from Fairview to Brereton, a distance of 8 miles. There is a similar dip from the Truax-Traer property, which is approximately 6 miles.

Using this information, I feel there is possibly 10,000 acres of coal with less than 100 feet of overburden, or 50,000,000 tons of coal in this area northwest of Canton. In this same field, there should be another 50,000,000 tons of coal with 100 to 170 feet of cover. *The above acreage consists of the best farm land in Fulton County.*

It should be noted here, that in the area between Canton and Glasford, there is possibly 6,000 acres of coal with less than 100 feet of cover. This area has not been drilled either.

Attached is a small map showing the relative position of properties and overburden contours.

Mr. R. J. Hepburn

INDUSTRY FIELD

We have examined our drill records at Industry and have compiled the average overburden.

The study was confined mainly to what is our present area and 80′ was the maximum overburden. I then went back over the field and made an estimate of the reserves under 65′ excluding all over 65′ except that which I feel is necessary to mine for accessibility.

The entire field has a reserve of 16,810,000 tons with an average ratio of 27.4.

Excluding that area with over 65′ of overburden not necessary to mine, the field reserves are 14,300,000 tons with a ratio of 26.2. This is an average overburden of 52.4′. Using averages only, the following is a typical drill hole.

	Percent	Feet
Surface	41.1	21.5
Gray Shale	25.5	13.4
Sandy Shale	25.6	13.4
Sand Rock	6.1	3.2
Sand	1.2	0.6
Mud	0.5	0.3

In looking over the drilling we have numerous holes which do not have any sandrock, but there are some with 3.0′ to 35′ of sandrock; where this does not appear we have sandy shale. I feel any future study should include core samples of this sandy shale.

I tentatively pick a spot of no coal area south and east of the center of the field for possible tipple location. This location would have an average haul of 1¾ miles.

Enclosed is a breakdown by sections of the coal reserves and the haul distance from above mentioned tipple location. Also enclosed are the drill logs per quarter section.

1939

ANNUAL REPORT

The United Electric Coal Companies

CHICAGO

YEAR ENDED JULY 31st 1939

PRESIDENT'S REPORT

To the Stockholders of
THE UNITED ELECTRIC COAL COMPANIES:

The annual report of The United Electric Coal Companies is submitted herewith.

Notwithstanding the depressed business conditions during the year ended July 31, 1939, your Company produced 2,078,606 tons of coal, an increase of 13 per cent above the production of 1,838,656 tons for the preceding twelve months. Total production of bituminous coal in the United States during the same period was 358,798,000 tons, compared with 361,559,000 tons for the twelve months ended July 31, 1938, a decrease of 3/4 of 1 per cent. The production of 2,078,606 tons of coal during the last fiscal year was the largest production in the history of The United Electric Coal Companies, the best previous year being 1930 when production was 1,897,319 tons.

The net income for the year ended July 31, 1939 was $167,196.98, (before deducting write off on contracts acquired in 1929, now expired or abandoned, $146,240.57) as compared with $226,795.10 for the previous year. This decrease in net income is due to a reduction of 10 cents a ton in the selling price of our coal, partially offset by a reduction of 6 cents a ton in operating cost.

The average wage rate per hour paid to its mine labor by The United Electric Coal Companies in the year ended July 31, 1939, was 93.0 cents as against an average of 92.5 cents for the bituminous coal industry in the State of Illinois. This compares with 68.5 cents, the average wage of all industry in the State of Illinois, also with 92.6 cents for the average wage in the automobile industry and 64.6 cents for all manufacturing industries in the United States.

During the year, the Company operated four mines with the following production in tons:

Fidelity	992,026
Freeburg	244,614
Cuba	271,250
Buckheart	570,806

All mines are in excellent physical shape and are well equipped to take advantage of any increase in sales. The Buckheart Mine continues as one of the lowest cost producers in the United States, and it has the further advantage that its production is now moving to new markets through the completion last November of the 8-mile railroad to our loading terminal on the Illinois River.

The total reserves of coal owned or controlled by the Company are estimated at 65 million tons, divided among the different mines as follows:

Fidelity	24,288,983 tons
Freeburg	2,225,655 tons
Cuba	2,959,718 tons
Buckheart	11,079,896 tons
Other properties	24,766,017 tons

These reserves may be further increased through purchase or lease of additional areas adjacent to each of the above mines.

In October of last year, in accordance with plans previously submitted to stockholders, $2,100,000 was borrowed from banks. With the proceeds the old Creditors' Agreement notes were paid in full, all outstanding equipment notes were redeemed, and the balance was used in building the railroad to Liverpool, and to increase the Company's working capital. As of September 15, 1939, this debt had been reduced to $1,703,823.51.

The officers of the Company, together with the officers of other coal companies throughout the United States, have devoted considerable time and effort to the work of establishing minimum prices under the provisions of the Guffey Act. There is, however, nothing definite to be reported to the stockholders at this time.

Since the close of the last fiscal year, your Company has cooperated in the formation of two marketing agencies, one in the Fulton-Peoria District, where the Buckheart and Cuba mines are located, and the other in the Belleville District which includes the Fidelity and Freeburg mines. It is expected that these agencies, to which most of the strip mine operators in these areas belong, will do away with some of the unfavorable conditions that have existed in the past. These organizations are sanctioned by the Guffey Act.

Respectfully submitted,
FRANK F. KOLBE,
President.

September 16, 1939.

A TEN YEAR RECORD OF GROWTH IN SERVICE

Even though you have an unusual interest in coal, it may never have occurred to you that, with the exception of food and water, coal is perhaps the most important and vital product known to man and is our greatest and most dependable source of useful energy.

Our economy is designed to function on power. In a handful of coal weighing less than a pound there is enough power to raise a weight of 33,000 pounds sixty feet. All the potential power of our reserves of oil and natural gas and of the water in our dams combined is only a

* * *

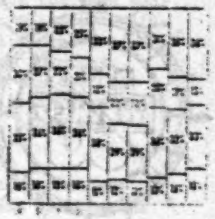
During the last two years we expended $3,094,165 for plant and equipment and $808,388 for lands. We have paid for these improvements with earnings and $735,278 of the proceeds of bank loans made in November, 1952. The remaining portion of these bank loans of $1,540,000 has been added to our working capital resulting in a net increase in working capital for the two years of $804,722.

PRODUCTION AND CONSUMPTION Last year was a period of considerable readjustment in the coal industry. Production for the country as a whole during our fiscal year was 404,000,000 tons, a decrease of 12% from the year before. The national production has been on the down trend for several years from its peak of 630,000,000 tons in 1947. In that year the railroad demand was 113,000,000 tons, and during our last fiscal year it was 21,000,000 tons. Residential consumption has also decreased from 99,000,000 to 59,000,000 tons in the same period. The decrease in railroad and residential business probably constitutes a permanent loss.

The bright feature in the coal industry has been the great increase in the coal used by the utilities. In 1940 this was 49,000,000 tons, and in our 1954 fiscal year it was 113,000,000. Thirty-six percent of our business is now with utilities and this percentage will increase.



Consumption of coal by various classes of customers during the past ten years

Attention: Mr. J. H. Morris, President

Dear Sir:

You have requested us to give you an opinion of the value as of December 31, 1959 of the physical assets owned by your corporation. Accordingly, we have made the studies deemed by us to be necessary to give you such an opinion.

Insofar as possible, our findings are presented in Exhibits A to G, inclusive. The text of the report is at a minimum. Our findings are related to the book values of the physical assets as shown on your December 31, 1959 balance sheet. There are several considerations to which we direct your attention.

The principal factor we use in arriving at an opinion of the value of an individual active mine as an operating entity is the anticipated amount of cash generation that may be reasonably expected to accrue during the remaining life of the recoverable coal reserves available to the mine. Obviously, no value except that of salvage attaches to a mine operating at an out-of-pocket loss.

The estimation of the amount of cash generation for each year of remaining life of the mine involves the estimation of sales realizations, of total costs, and of the amount of federal income tax on profits, if any, calculated without any deductions for interest. Obviously, value is a factor independent of the means employed in financing. It also involves the estimation of additional investment necessary for replacement equipment and sometimes for additional equipment and/or additional coal reserves.

The estimation of future profits after federal income tax involves an analysis of past profits and the conditions under which profits accrued. Future profits must reflect anticipated changes in overburden ratios and other conditions that affect sales volume, total costs and sales realization.

The value of an operating mine when based on cash generation includes its proportional share of the value of all company-owned facilities at head and branch offices such as automobiles, furniture and fixtures that do not in themselves produce an operating profit. Excluded only are those items such as the recently acquired steel barges, farm buildings and equipment, Kingston River Terminal and inactive coal reserves. The profit-producing potential of the steel barges is unknown. Farm buildings and equipment are not profit-producing. Income from Kingston River Terminal is nominal.

The value that we assign to property, plant and equipment at an active mine represents that amount in dollars as of December 31, 1959 on which, out of the estimated net cash generation at the end of each year, there will be available an amount which is sufficient to provide a return of 10 percent on the amortized value at the end of each year and leave a remainder which, if applied to reduce the value, will extinguish it during the life of the mine.

We point out that when and if 10 to 12 percent of the sales realization from an individual mine is recovered as a profit after federal income tax without considering any deductions for interest, the operating results are invariably satisfactory. Above this zone of 10 to 12 percent, the operating results are very satisfactory. Below this zone of 10 to 12 percent, the mine is probably marginal.

We also point out that approximately 59 percent of the total values are represented by active mines. The value of inactive coal reserves alone represents approximately 8 percent of the total value.

Appended to this report are Exhibits A to G, inclusive. These present details of the compilation of our values. We make these specific comments:

Exhibit A - Buckheart

This includes the railroad and dock installation. The cash generation pattern is well established. The operation is exceedingly profitable.

Exhibit B- Cuba

The cash generation pattern has been changed to a minor extent by the installation of a Kolbe Wheel in mid 1959. For our purpose we have assumed that $1,000,000 remains in the capital account six years hence, also that the salvage value of equipment other than the wheel will be $300,000. This mine is a profitable operation.

Exhibit C - Fidelity

This operation has been and continues to be a marginal one. Our value of $3,463,939 is less than the book value of $3,698,821. While the earnings record does not support the book value, we believe that the property could be sold for the book value.

Exhibit D - Mary Moore

The coal reserves at this mine will be completely depleted during September 1960. Our value reflects cash generation for nine months plus a salvage value, the chief part of which is concentrated in the 7400 dragline.

Exhibit E - Banner

There is no earnings record on which to project values. We recognize that the inherent quality of the coal moves it into a higher price bracket than that of Fulton County coal. However, the coal seam is thin and stripping ratio is high. There are certain to be some unanticipated problems. We believe that our value, which represents a write-up of approximately $1,700,000, is a reasonable expectation.

Exhibit F

This is a summary of values assigned to the physical assets.

Exhibit G

This represents the Inactive Coal Reserves. Our opinion is that the present value of these coal reserves is that shown as the book value. Our procedure on active mines has been based on an after-tax return of 10 percent. It is unlikely that there will be any substantial amount of depletion of these reserves during the next decade. On a 10 percent compound basis, the investment in the reserves may be said to be $4,961,450 ten years hence. We do not believe the present book value is excessive. At the same time, we see no logical basis for any write-up in value.

The North Cantus and Industry Fields will have substantially higher stripping ratios. In time, competitive conditions will permit their profitable development.

Advance Royalties

The December 31, 1959 balance sheet shows the amount of advance royalties to be $687,554. Almost 90 percent of this is charged to Buckheart and Banner Mines. While this item is not a "physical asset" we do comment that we believe the asset is sound.

General

We have made exhaustive checks on estimates of recoverable coal reserves. We believe the estimates prepared by the Company are accurate. We have checked the anticipated future stripping ratios. Some increases are indicated but we do not believe that the increases will have more than a nominal effect on our projections and then only during the late years when the present worth factor is low.

We have made careful checks on plant and equipment. In our opinion, operating results represent a reasonable expectancy from the equipment in use.

Our value of $23,446,225 as of December 31, 1959 exceeds the book value of $16,902,703 of that same date by $6,543,522. The amount of $16,902,703 is the sum of $16,321,169 and $581,534, the amount actually paid on option contracts. If this excess were added to the shareholders' equity as of that date, the total would have been $26,669,388.

Respectfully submitted,

FWH

REGARDING NEED FOR ADDITIONAL STRIPPING EQUIPMENT AT FIDELITY MINE

In the so-called Green Pit where we are currently working, the overburden is such that the 1650-B can mine nearly all of it without any additional stripping equipment. Toward the end of the field, a helper would be desirable to maintain production and costs.

This Green Pit will be mined out within two to two-and-a-half years. Beyond that, the estimated reserves at Fidelity that can be stripped is 23,000,000 tons. Investigation of the three different areas comprising this 23,000,000 tons shows overburden depths and hard rock requiring a helper for the 1650-B to mine it out economically and to mine all of the 23,000,000 tons. Without a helper, our production would be reduced from the current rate of 180,000 tons per month to about 125,000 tons, with a resultant increase in cost. Also, of this 23,000,000 tons, there is approximately 10,000,000 tons that could not be mined at all with the one machine (1650-B). Therefore the need for additional equipment has been established.

We feel a wheel, properly designed to work with the 1650-B, is the answer. The following information and estimates have been developed.

1. Bucyrus-Erie has a standard design and has built a wheel for Peabody and one for Truax. It is high enough for us, but for our purpose certain modifications of design seem necessary. They put a price on their standard design of $2,500,000, and an estimate on transportation and erection of $400,000. While we don't know exactly what the change in design we would need would cost, they have indicated that the engineering and other factors involved would cost somewhere in the neighborhood of another $400,000. So it appears we are thinking about something over $3,000,000 for a Bucyrus machine in place and ready to operate.

2. We have built four wheels, three of which are now in operation. The W-2 is at Buckheart, the W-3 at Banner, and the W-4 at Cuba. The W-3 was originally at Fidelity Mine but because of the design of this particular machine, never proved successful there.
It was redesigned and moved to Banner and our cost and profit record there will indicate its satisfactory performance.
The wheels at both Buckheart and Cuba are doing a very satisfactory job.
3. We have all of the engineering information, blueprints and so forth necessary to build the type of wheel we need at Fidelity. This, of course, is quite a cost saving.
The machine would be built higher, the digging end longer, and the stacker end some longer and higher to place the dirt back far enough in deep overburden to avoid slides. We would use the base, motors and quite a lot of other material from the 5561 Marion shovel which is now used as a stand-by at Fidelity. You will recall the details of trading this machine in and then buying it back at a cost of $250,000, including all parts.
4. Utilizing our engineering knowledge, blue prints, and experience, and building the machine on the site, would effect considerable savings. The repair parts in inventory for the 5561 and also repair parts in inventory for Wheels 2, 3 and 4 would be available for the W-5 machine.
5. Our estimate of the total cost, using our own people for the engineering and supervision, and contracting for the welding, erection and so forth, is $1,500,000. This does not include any capital charge for the material used from the Marion 5561. This is on our books at $_____ today.
We feel our estimates are within reason but for contingencies and unexpected difficulties, we could add considerably and still be way below the cost of buying a wheel from Bucyrus-Erie.

In our five-year budget for capital expenditures, we included $_____ in 1966 and $_____ in 1967.

We can build this machine and have it in operation within fourteen months. The best estimate from Bucyrus is eighteen months and probably longer.

6. John Murray has prepared financial data on return on investment and so forth, which is attached hereto.

GOVERNMENT EXHIBIT Kol. Dep. 61

THIS AGREEMENT made and entered into at Pittsburgh, Pennsylvania the 5th day of September, 1956, by and between THE UNITED ELECTRIC COAL COMPANIES, a Delaware corporation having its principal office in Chicago, Illinois, (hereinafter called "United"), and ALUMINUM COMPANY OF AMERICA, a Pennsylvania corporation having its principal office in Pittsburgh, Pennsylvania, (hereinafter called "Alcoa").

WITNESSETH:

WHEREAS, Alcoa desires to obtain options to purchase the coal and coal mining rights in and under certain lands located in Perry County, State of Illinois, together with all other available minerals and mineral and mining rights in said land, and

WHEREAS, Alcoa desires that said options be obtained without disclosing the identity of Alcoa, and

WHEREAS, United has indicated its willingness to obtain said options in the name of United and hold said options in trust for Alcoa and thereafter at the request of Alcoa, assign and convey said options to Alcoa, and

WHEREAS, Alcoa shall, from time to time, desire United to perform or cause to be performed certain prospecting, drilling, exploration and other work on said lands or relating to said lands, and

WHEREAS, United has indicated its willingness to perform or cause to be performed such prospecting, drilling, exploration and other work,

NOW THEREFORE, United and Alcoa, in reliance upon the covenants herein contained, hereby covenant and agree as follows,

intending to be legally bound thereby:

1. United shall undertake to obtain, in its own name and without disclosing that it is acting for Alcoa, recordable and assignable options for the purchase of the coal and coal mining rights, together with all other available minerals and mineral and mining rights, in at least Eighteen Thousand (18,000) acres but not more than Twenty-Five Thousand (25,000) acres of land located east and north of Pinckneyville, Perry County, Illinois as outlined in red on the map marked "Exhibit A" and attached hereto, paying to the owner or owners of said land as consideration for each option so obtained the sum of One Dollar ($1.00) per acre of land. United shall, in so far as is practicable, obtain said options in such a manner that the optioned tracts of land will be contiguous and constitute a solid block.

2. Until United is otherwise directed, in writing, by Alcoa, each option so obtained by United shall be in the form marked "Exhibit B", attached hereto, and shall provide for the payment to the owner or owners of said land, in the event the option is exercised, of a total purchase price not to exceed the sum of Fifty Dollars ($50.00) per acre of land.

3. United shall without undue delay cause each option so obtained to be recorded in the appropriate records of Perry County, Illinois.

4. United does hereby acknowledge and declare that it will hold said option in trust for Alcoa, and that United will not claim to have any right, title or interest in said options to its own use or benefit. United does hereby covenant with Alcoa that it will, immediately after the same has been recorded, convey and assign and deliver each option so obtained by United to Alcoa or to such other person or corporation as Alcoa shall in writing nominate or appoint.

(5) At such time as Alcoa shall designate, United shall cause the optioned lands to be properly drilled on approximately one-half mile centers and shall cause the cores to be examined and logged by a competent consulting engineer. United shall cause the coal samples to be analyzed by Commercial Testing Laboratory in Chicago, Illinois and shall promptly deliver to Alcoa the results of such analysis.

(6) On or before the tenth day of each month, United shall invoice Alcoa for, and Alcoa shall thereafter promptly pay, such charges as shall be due and owing to United by Alcoa on account of performance hereunder by United during the previous month. Such charges shall consist of the following:

A. Payments made to the owners of land optioned in accordance with the terms hereof and the cost of recording the options.

B. Payments made for salaries and wages of persons employed by United solely for the purpose of obtaining options hereunder.

C. An amount which is equal to one and one-half times the portion of the salaries of United's engineering and land acquisition employees which is attributable to United's performance hereunder on the basis of actual time spent by such employees in performance hereunder.

D. The actual cost of causing the drilling, examination and logging of cores, and analysis of samples to be performed pursuant to Article 5 hereof.

E. Expenses incurred for meals, lodging, transportation, telephone and telegraph messages, engineering supplies and office supplies.

7. United shall, at any time upon receipt of written notice from Alcoa to do so, immediately cease, or temporarily suspend, the obtaining of options hereunder.

8. This agreement may be terminated by either United or Alcoa by giving thirty (30) days prior written notice of such termination.

9. In the event Alcoa decides to drop the options acquired under this Agreement, said options shall at the election of United be reassigned by Alcoa to United upon the reimbursement by United to Alcoa of all charges theretofore paid by Alcoa to United pursuant to the provisions of Paragraph 6 hereof, plus any renewal payments theretofore made on said options by Alcoa.

10. Notices to United provided for herein shall be deemed to be properly given when deposited in the United States mail, registered and postage prepaid, addressed to:

T. H. Latimer
The United Electric Coal Companies
307 North Michigan Avenue
Chicago 1, Illinois

Notices to Alcoa provided for herein shall be deemed to be properly given when deposited in the United States mail, registered and postage prepaid, addressed to:

R. F. Miller, Mining Division
Aluminum Company of America
1501 Alcoa Building
Pittsburgh 19, Pennsylvania

11. This agreement shall inure to the benefit of and shall be

binding upon the parties hereto and their respective successors and assigns.

IN WITNESS WHEREOF the parties hereto have caused this agreement to be executed by their duly authorized officers the day and year first above written.

COMPARISON BETWEEN TRUAX-TRAER COAL COMPANY

AND

THE UNITED ELECTRIC COAL COMPANIES

October 8, 1968

Herewith a comparison of ourselves and Truax-Traer based primarily on tons produced in each locality per annum showing what we would get in a merger and what we might be giving. The earnings by United and Truax per ton from the coal in each area should be the same over a period of time, as the overburden in each area is about the same on the average. Some years overburden will be much lower at one mine than another, resulting in lower stripping cost and lower blasting cost, but it will average out.

At present in Fulton County we are producing the same tons as Truax, but our potential reserves are 65 per cent greater, and ultimately this will be represented in production and sales. We are now building a new, larger wheel at our Cuba mine which will increase our capacity there 600,000 tons a year, and we are also considering the acquisition of a mine in the Banner area on the Illinois River just below Peoria. This mine is now producing 200,000 tons a year, and we might increase this to 700,000 tons. If we did this, our total capacity in Fulton County would be 3,300,000 tons, as compared with Truax's present 2,100,000. In Southern Illinois Truax has much larger reserves than we do, but I do not think this is a particularly good place to have reserves. Our Danville and Buffalo creek mines are very profitable mines, as profitable as or more profitable than similar mines in Fulton County. The Truax mines in West Virginia and North Dakota are out of our territory, and I do not know anything about them.

More of the benefits would come from the Truax properties than from our own. At present the tonnage from the Little Sister properties goes to the Little Sister washer and then goes by Burlington Railroad to the Truax dock. We would take this to Buckhorn and then down our railroad. At the Shakerag mine of Truax, the combined company might save money by putting in a washer to prepare only two sizes of coal, 2 x 6 and 2 x 0. The various other sizes could be produced at the Fidelity washer. This would mean for a cheap and economical-to-run washer at the Shakerag properties.

For a consolidated company, the West Virginia tonnage does not have as much purpose as in the present Truax company, as in a consolidated company it would be only a fifth of the total output, instead of a third, and if certain expansion that we are contemplating were put through, it would be only a sixth. Under these circumstances, it would be only the tail of the dog, with its own mining and selling problems that would be completely different from the problems of the other 80 per cent. I doubt whether under these circumstances it would get the same progressive, forward-looking attention that the other 80 per cent would, and whatever it did get might detract from the attention that should be given to the properties in the Middle West. With the present move toward consolidations in the East and toward acquisitions of property, it might be that this property could be sold and the funds distributed to the present Truax stockholders, or they might be given preferred stock.

If the Eastern properties were taken out, our relative productions would be as follows:

	United's Production	Trumm's Production	Excess of Trumm's Production Over United's
Fulton County Railroad - Profits in Tons of Coal Equivalent	300,000	-	(300,000)
Danville	300,000	-	(300,000)
Buffalo Creek	300,000	-	(300,000)
Total	3,000,000	2,100,000	(900,000)
Southern Illinois	1,500,000	2,500,000	1,000,000
Total	4,500,000	4,600,000	100,000
North Dakota	-	1,500,000	1,500,000

The earnings from the 6,100,000 would not be far different from the earnings from the 4,600,000.

We are in a position now to go ahead with some expansion, and if we did so, we would be sharing the benefits of this with Trumm. On the other hand, they would be paying their share of it. We have the possibility now of earning $3.50 or $4.00 a share from our present properties and of opening new mines which would increase these earnings. I just want to be sure that in a merger our earnings per share per annum would be increased.

COMPARISON OF NET INCOME IN YEAR ENDED JULY 31, 1956

United Electric earned $1,631,055 or $2.45 a share on 677,920 shares for the year ended July 31, 1956. Truax-Traer during its fiscal year ended three months earlier - April 30, 1956 - earned $3,212,618 which, after preferred dividends, was equivalent to $2.81 a share on the 1,149,530 shares of common stock outstanding at April 30, 1956. Included in the Truax earnings of $3,212,618 is $567,816 after taxes or 49 cents a common share realized from the sale during the year of coal lands in Western Kentucky. Excluding the capital gain and changing the year to July 31, Truax's earnings were $2,991,169. This is $2.20 per share on the 1,358,840 shares outstanding allowing for full conversion of the preferred but does not include shares recently issued for the acquisition of Little Sister. Based on earnings for the year ended July 31, 1956, United should get 1 1/10 shares of Truax but United's earnings last year do not reflect the present and future situations.

ESTIMATED NET INCOME FOR UNITED IN YEAR ENDED JULY 31, 1957

For the present fiscal year ending July 31, 1957, it is estimated that United Electric's earnings will be as follows:

Mine	Tonnage	Operating Income Per Ton	Operating Income Amount
Cuba	800,000	$1.00	$ 800,000
Buckhoart	1,300,000	.85	1,105,000
B.R. & R.T.	(1,200,000)	.25	300,000
Fidelity	1,500,000	.50	750,000
Mary Moore	300,000	1.00	300,000
Buffalo Creek	300,000	1.00	300,000
	4,200,000		$3,585,000
Less - Federal income taxes			1,100,000
Net income			$2,486,000
Net income per share on 677,920 shares			$ 3.62

United Electric is building a new wheel for Cuba which will increase the capacity of that mine by 800,000 tons. It is estimated that Cuba's costs will be reduced 10 cents to 15 cents a ton using the new wheel, and when the added capacity is sold, that will result in an additional cost reduction.

The north field at Buckheart has been opened, and United is about to move to that area. When this move is completed, Buckheart's costs will be reduced, as the average overburden ratio is 14 to 1 in the north field, compared with 15.9 to 1 during the past year.

At Fidelity the deepest overburden ratio is now being stripped. The average depth of overburden was 64 feet this past year, and some was 80 feet with very heavy rock. Across the road is 11 million tons under 80 feet.

CASH THROUGH AND WORKING CAPITAL POSITION

United Electric's working capital was $3,179,296 at July 31, 1956. An estimate of the increase in working capital for the fiscal year 1956 is as follows:

	Amount	Per Share
Additions:		
Net income from operations	$2,435,000	
Add depreciation and depletion	1,480,000	
	$3,905,000	$5.76
Reductions:		
Land payments	$ 460,000	
Plant and equipment purchases	500,000	
Dividends	678,000	
	$1,628,000	2.40
Estimated increase in working capital before other capital expenditures	$2,277,000	$3.36

At the end of the present fiscal year United Electric's working capital could be over $5,000,000, or the anticipated increase would be available to add new mines or for other purposes.

Truax-Traer's working capital April 30, 1956, was $9,886,184. Long-term indebtedness, of which United has none, was $3,816,622. Deducting cash received from this, to make figures comparable, would reduce Truax's working capital to $6,069,638.

United has followed a different policy in the purchase of coal lands in Fulton County. Truax has an investment in lands in Fulton County of $977,927. United has an investment of $4,095,068. United is now negotiating for the sale of this land which, if done, would increase its working capital.

United Electric's present mines are equipped to handle all the overburden at those mines without additional equipment, except for the expenditure of $1,250,000 for a new wheel at Cuba, which will increase the capacity of that mine by a half-million tons a year.

RESERVES

Fulton County and Adjacent Area

Fulton County is often called the most profitable coal-mining district in the United States. A comparison of the Fulton County area reserve tonnages of United Electric at July 31, 1956, and of Truax-Traer as of about a year earlier is as follows:

	Reserve Tons	Overburden Ratio
Cuba	6,505,939	18.6 to 1
North Canton	8,251,630	15.7 to 1
	14,757,569	
Duckheart	21,694,771	14.0 to 1
Banner	3,421,921	17 to 1
McDonough County	8,978,117	22.7 to 1
	12,398,038	
	48,720,608	

In addition to the above tonnage, United can probably acquire 10,000,000 additional tons in the North Canton area, 9,000,000 tons for Duckheart,

6,500,000 tons in the Banner area, and 1,000,000 tons in McDonough County - a total of 28,500,000 additional reserves. United Electric's reserves in this area would then be:

	Reserve Tons	Overburden Ratio
Cuba	6,805,239	
North Canton	18,251,630	
	24,737,569	
Buckheart	30,536,771	
Banner	9,621,021	
McDonough County	9,978,117	
	19,893,068	
	75,230,408	

United is now selling 2,100,000 tons per annum from Fulton County. The above reserves would give United a life in the Fulton County of 35 years. United is now building a wheel at Cuba which will increase this capacity to 2,600,000 tons per annum and is also considering the purchase of a mine in the Banner field with a present production of 200,000 tons a year which will later be increased to 700,000 tons making a total for this area of 3,300,000 tons per annum.

The Truax reserves in Fulton County are:

	Reserve Tons	Overburden Ratio
Platt	20,644,339	13.5 to 1
Little Sister	10,000,000	
	30,644,339	
Probable Future Acquisitions	15,000,000	
	45,644,339	

Truax is now selling 2,100,000 tons per annum from Fulton County. These reserves would permit Truax a life in Fulton County of 22 years.

Southern Illinois

In Southern Illinois United Electric and Truax-Traer have the following reserve tonnage:

	Reserve Tons	Overburden Ratio
United Electric:		
Fidelity	27,661,489	10.2 to 1
Annual Production	1,500,000	
Trunk-Treer:		
Shawnee - Pyramid	31,603,594	12.5 to 1
Burning Star - Strip	6,672,169	15 to 1
Sparta	10,571,000	11.2 to 1
Jamestown	18,302,400	9.3 to 1
Total Strip	67,152,143	
Burning Star - Drift	12,510,027	
Total Trunk	79,662,170	
Annual Production	2,500,000	

The foregoing reserve tonnages are as of July 31, 1956, for United Electric and as of about a year earlier for Trunk-Treer.

Mary Moore

At July 31, 1956, United Electric had reserve tonnage at the Mary Moore mine near Danville, Illinois, amounting to 1,118,583 at an average overburden ratio of 10.2 to 1. We are now obtaining options on an additional several million tons in this field.

Buffalo Creek

United Electric has reserve tonnages at Buffalo Creek at July 31, 1956, as follows:

	Reserve Tons	Overburden Ratio
Strip Coal	1,540,166	17.3 to 1
Deep Coal	5,762,668	

United as an option to acquire on a royalty basis from Jenkins Coal Mining Company additional reserves of #6 coal which are located about five miles from the Buffalo Creek property. The Jenkins property has possibly the largest reserves of #6 coal in Western Kentucky. About 2 million tons of #4 coal are also included in the option.

West Virginia and North Dakota

In addition to its Illinois mines, Truax has West Virginia and North Dakota properties:

West Virginia:	
Reserves	187,280,153
Production Year Ended April 30, 1956	2,489,905
North Dakota:	
Reserves	103,209,828
Production Year Ended April 30, 1956	1,676,836

Miscellaneous

United Electric owns or controls 1,724,998 tons of strip coal in Ohio County, Kentucky; 2,301,872 tons of strip coal in Oklahoma; 1,795,360 tons of deep coal in Vermilion County, Illinois; and 883,084 tons of deep coal in Perry County, Illinois, leased to Union Electric.

RECAP

United Electric with its present mines can produce 4,500,000 tons and could earn $2,700,000 or $4.00 a share on this production. These earnings assume that we can build up our summer business in Fulton County.

United Electric in 1958 will increase its capacity 800,000 tons per year through the operation of its new wheel at the Cuba mine. It is believed this additional coal can be sold to the new power plant to be built by the Central Illinois Light Company in Peoria or to other customers.

United Electric may also open a new mine in the Banner Field on the Illinois River near Peoria. This coal, when washed, would have 12,000 B.T.u's. This would be West Kentucky coal on an Illinois River freight rate. This coal would have a market value at utility plants on Lake Michigan of $4.50 a ton. Our profit might run $1.50 a ton and be greater than at any mine we now have. The total profit in this field might be $1,050,000 a year, or $700,000 after taxes.

If the Jenkins field works out as we think it may, it would be a very substantial earner, as this coal sells for $5.50, and with the sort of equipment that we are thinking of for this field, we should earn $2.00 a ton before taxes. We could probably sell 600,000 tons a year from this mine on which the earnings after taxes would be $500,000.

The additional net income from these two properties might be $2.00 a share on our stock.

TRUAX-TRAER COAL COMPANY
AND
THE UNITED ELECTRIC COAL COMPANIES
ANNUAL SALES IN TONS

Year Ended April 30, 1956

		Truax-Traer	United Electric
Fulton County:			
Pratt	1,521,547		
Little Sister	636,502	2,158,049	
United Electric			1,900,231
Mary Moore			200,023
Buffalo Creek			312,725
		2,158,049	2,412,979
Southern Illinois		2,379,581	1,217,025
		4,537,630	3,630,004
West Virginia		2,469,805	
North Dakota		1,476,966	
Total		8,484,401	3,630,004

Our railroad has a net profit before taxes of $300,000 which is the amount of profit that could be made from 300,000 tons of coal.

Profitwise we now have the equivalent of 3,950,000 tons of coal from present production and with Banner and Jenkins present production added this would be 4,450,000 tons. With Banner and Jenkins operating the way we might develop them, our production would be greater.

Present United Electric and Truax-Traer-Little Sister Properties
(Does not include Banner or Jenkins acquisitions)

If United Electric were to receive 1 1/10 shares for each share of Truax, the consolidated company would have 2,280,000 shares, of which United would have 750,000 shares, or a third:

	United's Present Production	Consolidated Companies' Production	United's Share in Consolidated Production 1/3 of Total Tons
Fulton County	2,100,000	4,200,000	1,400,000
Railroad - Profit in Tons of Coal Equivalent	300,000	400,000	150,000
Danville	300,000	300,000	100,000
Buffalo Creek	300,000	300,000	100,000
	3,000,000	5,200,000	1,750,000
Southern Illinois	1,800,000	4,000,000	1,335,000
	4,800,000	9,200,000	3,085,000
West Virginia	-	2,600,000	833,000
North Dakota	-	1,500,000	500,000
Total Tons	4,800,000	13,200,000	4,418,000

United would give up the earnings from 1,280,000 tons of Fulton County or equivalent production and 167,000 tons of Southern Illinois production; it would receive the earnings of 1,333,000 tons of West Virginia and North Dakota production.

Present United Electric and Truax-Traer-Little Sister Properties
(Does not include Hamer or Jenkins acquisitions)

If United were to receive 1 1/2 shares of Truax-Traer, the consolidated company would have 2,500,000 shares, of which United would have 1,000,000 shares, or 40 per cent:

	United's Present Production	Consolidated Companies' Production	United's Share in Consolidated Production 40 Per Cent
Fulton County	2,100,000	4,200,000	1,680,000
Railroad - Profit in Tons of Coal Equivalent	300,000	450,000	180,000
Danville	300,000	300,000	120,000
Buffalo Creek	300,000	300,000	120,000
	3,000,000	5,250,000	2,100,000
Southern Illinois	1,500,000	4,000,000	1,600,000
	4,500,000	9,250,000	3,700,000
West Virginia	-	2,500,000	1,000,000
North Dakota	-	1,500,000	600,000
Total Tons	4,500,000	13,250,000	5,300,000

United would give up 800,000 tons of Fulton County production or equivalent production and receive 100,000 tons of Southern Illinois production along with 1,600,000 tons of West Virginia and North Dakota production.

United Electric with Banner and Jenkins mines and Truax-Traer with Little Sister

If United Electric were to receive 1 1/10 shares for each share of Truax, the total capitalization of the new Truax would be 2,250,000 shares, of which United would receive 750,000 shares, or a third:

	United's Present Production with Banner and Jenkins Developed	Consolidated Companies' Production	United's Share in Consolidated Production 1/3 of Total Tons
Present Production:			
Fulton County	2,100,000	4,200,000	1,400,000
Railroad - Profit in Tons of Coal Equivalent	300,000	450,000	150,000
Danville	300,000	300,000	100,000
Buffalo Creek	300,000	300,000	100,000
	3,000,000	5,250,000	1,750,000
Likely Production			
Banner	700,000	700,000	233,000
Jenkins	600,000	600,000	200,000
	4,300,000	6,550,000	2,183,000
Southern Illinois	1,500,000	4,000,000	1,333,000
	5,800,000	10,550,000	3,516,000
West Virginia	-	2,600,000	833,000
North Dakota	-	1,600,000	500,000
	5,800,000	14,550,000	4,849,000

United would give up 2,284,000 tons of Midwestern production for 1,333,000 tons of West Virginia and North Dakota production.

United Electric with Banner and Jenkins Mines
Truax-Traer with Little Sister

If United were to receive 1 1/2 shares of Truax-Traer, the total new capitalisation would be 2,600,000 shares, of which United would get 1,000,000 shares, or 40 per cent:

	United's Present Production with Banner and Jenkins Developed	Consolidated Companies' Production	United's Share in Consolidated Production 40 Per Cent
Present Productions:			
Fulton County	2,100,000	4,200,000	1,680,000
Railroad - Profit in Tons of Coal Equivalent	300,000	450,000	180,000
Danville	300,000	300,000	120,000
Buffalo Creek	300,000	300,000	120,000
	3,000,000	5,250,000	2,100,000
Likely Productions:			
Banner	700,000	700,000	280,000
Jenkins	600,000	600,000	240,000
	4,300,000	6,550,000	2,620,000
Southern Illinois	1,500,000	4,000,000	1,600,000
	5,800,000	10,550,000	4,220,000
West Virginia	-	2,600,000	1,000,000
North Dakota	-	1,500,000	600,000
Total Tons	5,800,000	14,665,000	5,820,000

United would exchange 1,580,000 tons of Midwestern tonnage for an equivalent amount of West Virginia and North Dakota tonnage.

January 30, 1956

Mr. A. H. Truax
President and Chairman of the Board
Truax-Traer Coal Company
111 North Wabash Avenue
Chicago, Illinois

Dear Mr. Truax:

In this cover are my findings and estimates of the strip mining possibilities and economic opportunities in the Fulton and Perry County areas of Illinois.

I believe the report to be realistic, conservative and to present a fair estimate of operational opportunities together with indicated savings possible, based on current information.

In my opinion the operational savings possible contained in this report, together with economies indicated and apparent which should be developed from a separate tax and financial study, make the proposed merger most attractive and sound. Every effort should be made to consummate the combination.

Yours very truly,

/s/ Theron G. Gerow

PART I

SUMMARY AND CONCLUSIONS

This section is presented first rather than at the end to aid in a quick digest of the report and to serve as a ready reference to the more important points of its contents.

SUMMARY (Operational)

Fulton County

1. The combined Fulton County tonnage of Truax-Traer, United Electric and Little Sister was 4,040,936 tons for the 12 months period December 1, 1954 to November 30, 1955. (See Exhibit I)
2. This tonnage was processed over 4 preparation plants from 4 mining operations.
3. The combined reserves of the three companies total about 59,000,000 tons.
4. The combined potential tonnage is estimated at 76,000,000 tons or a life at the present rate of production of 19 years.
5. Unlike most mergers the reserves and operations of the three companies are extremely closely related and their reserves practically contiguous. Such a close interlocking of interests presents many opportunities for operation improvements and economies.
6. Of the combined Fulton County production 2,466,728 tons moved over the Illinois River facilities.
7. River tonnage other than from Buckheart moved at a freight disadvantage over Buckheart's cost of operating their own rail and river facilities.
8. 1954 production at Buckheart has demonstrated a potential single shift capacity at 225 operating days of 1,125,000 tons. This tonnage can be

increased either by improving daily capacity or by working more days.

9. Without question a double shift operation at Buckheart would be more economical in every way; would more than take care of the present combined river tonnage and would provide a foreseeable life of about 10 years. The mine has a reserve of approximately 25,000,000 tons.
10. Of the remaining Fulton County reserves totalling about 51,000,000 tons in the Canton-Fiatt-Cuba triangle, 11,500,000 tons lie within a 3 mile radius of the Fiatt Tipple and a total of at least 17,500,000 tons within a 4 mile radius.
11. At 1954 rates of production, Fiatt has demonstrated a production capacity of 1,460,000 tons based on 225 working days, and in the 12 month period to November 30, 1955 produced 1,503,850 tons working 235 days, almost exactly the difference between present Fulton County requirements and the Buckheart double shift capacity.
12. The Fiatt and Buckheart Tipples can produce the present Fulton County combined tonnage requirements for the next 11 to 12 years.
13. Two tipples will adequately produce the present combined Fulton County tonnage requirements. The St. David and Cuba Tipples can almost immediately be shut down.
14. The balance of the reserves or about 33,500,000 tons (Exhibit III) center on a point near the old Eagle Mine just west of Canton. In addition there are about 1,000,000 tons in the Skyrocket area which should logically be produced through the Buckheart Tipple.
15. Of the 33,500,000 tons concentrated in a block just west of Canton about 80% lie within a 2 mile radius and almost 100% including most of the Cuba reserves lie within a 3 mile radius of the proposed East Field Tipple site. More coal property is adjacent to the block and is available.

16. There is a logical location for a new tipple to handle the 33,500,000 ton reserve directly west of Canton near the T.P. & W. Railroad where a C.L. & Q. connection is also possible.
17. If a T.P. & W. rail connection is desirable or important, such a route has previously been surveyed into the Fiatt Tipple.
18. Discussion of the Cuba Tipple and other operational problems are carried in Part III—Mining Operations.
19. The opportunities and possibilities of operational advantages and economics are very apparent under merged interests of Truax-Traer, United Electric and Little Sister in the Fulton County area.
20. In addition to general merged interests there are many economies possible such as better application of the several units of stripping equipment available, the use of higher capacity trucks, double shift, etc.

Perry County

1. The combined Perry County tonnage of Truax-Traer and United Electric was 2,245,613 tons for the 12 month period December 1, 1954 to November 30, 1955. (See Exhibit I)
2. This tonnage was processed over two cleaning plants from three mining operations.
3. The combined reserves of the two companies in Perry County are 54,379,389 tons with a combined potential of at least 56,000,000 tons or a life at present rates of production of about 25 years.
4. Again, as in Fulton County, these reserves are very closely integrated, being only separated by the Illinois Central Railroad and are practically all contained within a circle of 3 miles radius centering along the I.C. tracks near William Creek.

5. The Pyramid Mine is within about a year of working out.

6. Burning Star Mine No. 2 is under a 25¢ per ton burden in shipping coal to the Pyramid Tipple for cleaning. This cost will also be added to the Pyramid tonnage unless a new tipple location becomes available promptly.

7. Truax-Traer must definitely make a decision very shortly as to a new tipple site.

8. The Fidelity Tipple has a demonstrated capacity based on 225 working days of about 1,135,000 tons. Double shift, it would more than take care of combined present tonnage requirement. However, it is a relatively high cost tipple.

9. The Fidelity Mine is now hauling on radii of 3 and 4 miles with most reserves at the 4 mile radius. It cannot reach Truax-Traer reserves under a 5 to 6 mile radius.

10. One Tipple on a double shift basis properly located can adequately process Perry County tonnage requirements.

11. It seems logical for maximum economy, operational advantages and long range planning to consider a new modern and throughly efficient tipple near the center of some 56,000,000 tons of coal reserves.

12. Discussion of the Perry County tipples is carried under Part III—Mining Operations.

13. There is a splendid opportunity for operational advantages and economies in merged Perry County operations of Truax-Traer and United Electric.

14. In addition to apparent economies from merged operations there are many other operational savings possible from the use of high capacity haulage units, double shift, more economical use of available stripping units, etc.

CONCLUSIONS

1. From the Summary above and the study carried in the body of the Report there seems every reason from an operational point of view to merge the interests of Truax-Traer, United Electric and Little Sister in Fulton County, Illinois and Truax-Traer and United Electric in Perry County, Illinois.
2. Operational advantages and economies resulting will be substantial.
3. Sales advantages will provide better coverage of the market areas at considerable savings in cost of sales per ton.
4. Administration and management should be able to function more capably and efficiently at a considerable savings in cost per ton.
5. Results of merged interests, without the scope of this report, such as tax advantages, write-off of obsolete or non-profitable equipment and operations, stock values, financial factors, etc., are all very fertile fields of investigation which will produce additional savings.
6. No adverse or detrimental factors which might affect the proposed merger have come to light in this preliminary study.

RECOMMENDATIONS

1. Merge Truax-Traer Coal Company, United Electrict Coal Companies and Little Sister Coal Company.
2. In Fulton County:
   (a) Double shift the Buckheart Mine for full production of river shipments.
   (b) Shut down the Cuba Mine and move its stripping and loading equipment to Buckheart for added mining capacity.
   (c) Process the Skyrocket reserves of Little Sister Coal Company over the Buckheart

Tipple. 60% of Little Sister's tonnage presently moves to the River.

(d) Shut down the St. David operations of Little Sister and make available the 40 yd. 5561 Marion stripping shovel to the Fiatt operation.

(e) Operate the Fiatt Mine full single shift capacity at about 235 working days for the balance of Fulton County tonnage requirements.

(f) Install 50 ton or larger haulage units at both Fiatt and Buckheart mines.

(g) Engineer and plan new tipple at a site directly west of Canton for production of remaining reserves, including Cuba and Little Sister, to be ready in about 10 years or sooner if production demand requires.

(h) Consider T.P. & W. rail connection to Fiatt Tipple.

(i) Consolidate and streamline all Fulton County supervision, engineering, management and administration.

3. In Perry County:

(a) Plan and build a centrally located tipple to handle the combined Perry County tonnage, to be ready as soon as possible.

(b) Shut down the Fidelity and Pyramid Tipples.

(c) Double shift the new tipple.

(d) Replace all haulage equipment with 50 ton or larger units for double shift service.

(e) Provide both Illinois Central and Missouri Pacific rail connections to the new tipple.

(f) Consolidate and streamline all Perry County supervision, engineering, management and administration.

4. Combine and streamline all sales, management, administration and accounting departments and functions of Truax-Traer and United Electric for maximum efficiency and economy.

5. Study, under capable direction, the possibilities under a merger of tax and financial advantages.

ESTIMATED SAVINGS

A summary of estimated savings possible under a merger of Truax-Traer and United Electric also Little Sister in Fulton County follows. Only the effect of advantages in Fulton County and Perry County, Illinois have been considered. Details and basis of estimates are carried in Part III—Mining Operations and Part IV—Selling and Administration.

Estimated Savings

Fulton County Operations	$2,022,515.00
Perry County Operations	1,178,935.00
Selling and Administration	575,240.00
Market Stability	730,000.00
Total	$4,506,690.00

It may be well to call attention to the fact that the above total on factors covered by this report represents $2.00 a share or more on the combined shares of stock of Truax-Traer and United Electric giving credit for the inclusion of Little Sister and perhaps some stock adjustment.

ESTIMATED CAPITAL EXPENDITURES

A preliminary estimate of capital investments required to accomplish the above savings is as follows:

Fulton County	$ 985,000.00
Perry County	2,453,000.00
Total	$3,438,000.00

It should be clearly pointed out, however, that Truax-Traer is faced with an estimated expenditure of about $2,688,000.00 in any event with only relatively minor savings resulting. Hence:

CAPITAL EXPENDITURES
CHARGEABLE TO MERGER—$750,000.00

In my opinion, based on the above study, such a merger would result in a substantial increase in both dividends and market value to stockholders of both companies due to increased efficiency of operations and substantial savings possible in practically all departments of the combined companies.

The present trend and ultimate solution to a sound and economic coal industry is fewer and larger coal companies under competent and far seeing management with a willingness to meet and solve the problems of the industry cooperatively.

Respectfully submitted,

/s/ Theron G. Gerow
THERON G. GEROW
Mining Consultant and
Engineer

PART II

SCOPE OF REPORT

This report attempts to evaluate the operational advantages and economics possible under merger operations and interests of Truax-Traer Coal Company, The United Electric Coal Companies and Little Sister Coal Corporation.

Interests of the three companies are only interlocked in Illinois. The three companies are very closely related in both mining and sales in Fulton County and Truax-Traer and United Electric in Perry County.

The nearly contiguous and interlocked situation of the mining operations and coal reserves in both counties presents unusual opportunities for economics and operational savings in practically all departments of the companies, a condition not generally found in the consideration of coal mergers.

Therefore, for the purposes of this preliminary report, its scope is limited to the following:

1. The report is limited to a study of Fulton and Perry Counties, Illinois.
2. All other operations of the companies involved are separate and must stand on their own as to final value to the proposed merger.
3. For the present such separate operations can be assumed to contribute to the merged company in proportion to their present contribution to the parent company.
4. The report is based on data and information furnished by Truax-Traer, United Electric and Little Sister coal companies, and estimates where exact information was lacking.
5. The reports attempts to form a basis for the most economical consolidated operation of the several Mines involved.
6. The report attempts to point out and evaluate combined long-term possibilities, advantages and economics of operation.
7. The report does not cover any tax or financial advantages that will undoubtedly result from such a merger.
8. The report does not cover the probable effect on stock dividends or market value of stock.
9. The report only covers in a general way the effect of combined management, sales and administrative functions, giving credit chiefly to the accrued benefits resulting from merged Illinois interests.
10. The report does not attempt to make any estimates or evaluate the probable equities of the three companies in the proposed merged company.

PART III

MINING OPERATIONS

Consideration of mining operations of Truax-Traer Coal Company, The United Electric Coal Companies and Little Sister Coal Corporation under a proposed merger

is limited to Fulton and Perry Counties in the State of Illinois.

Other mining operations of Truax-Traer and United Electric are, for the purposes of this report, assumed to contribute to the merged company in proportion to their present contributions to their parent companies. No major operational savings would be expected from such other operations as a result of a merger.

The situation in both Fulton and Perry Counties, Illinois is considerably different and probably unique in merger consideration. The reserves of the companies are contiguous and mining operations contained in a circle of relatively small radius in both counties. (See Exhibits III and IV).

Operating conditions, coal quality, preparation plants, equipment, methods of operation, costs, etc. are either identical or nearly so in each county.

Joint operations in Illinois naturally divide themselves for study into the Fulton County area (Exhibit III) and the Perry County area (Exhibit IV) and will be so analyzed.

FULTON COUNTY

The combined production of the three companies in Fulton County for the 12 months prior to November 30, 1955 was 4,040,936 tons, of which 2,466,728 tons were shipped via the Illinois River over dock facilities of the companies.

The coal was produced from 4 separate operations over 4 tipples. All operations and coal reserves are contained in a circle of approximately a 9 mile radius.

Owned and leased coal reserves in this area total 59,-000,000 tons and a conservative estimate of a potential reserve is 76,000,000 tons.

The Buckheart Mine of United Electric has its own rail and dock facilities for river shipments. The other mines are under a cost handicap on river shipments having to add either a Burlington handling charge to the Buckheart facilities or the established rail rate to the Liverpool Dock owned and operated by Truax-Traer.

This is important as over 60% of the combined Fulton County tonnage moves via the Illinois River.

Please refer to Exhibit III for a clearer picture of the mining situations of the several mines which follows.

Fiatt Mine (Truax-Traer)

The Fiatt Mine produced 1,603,850 tons in the 12/1/54 to 11/30/55 period and worked 235 days.

It has proven average tipple capacity of 6500 tons per shift which for 225 days of work indicates a single shift potential of 1,460,000 tons annually.

The Fiatt Mine has the best operating conditions and is the lowest cost operation in the area.

The Tipple has had recent improvements and additions which have brought its capacity up to the highest of the four tipples being considered and costs are well in line and actually slightly below United Electric's average Fulton County preparation costs.

The mine has a reserve tonnage of 20,444,339 tons, of which 11,500,000 tons of low overburden coal are within a 3 mile radius with an average radius haul of less than 2½ miles.

The potential tonnage adjacent to the Tipple, including Little Sister's Cuba acreage at a 4 mile average haul, will exceed 17,500,000 tons giving an indicated life of low cost coal at maximum single shift operation of about 11½ years.

Fiatt has already made a start on large capacity haulage trucks with six 45 ton units. A high capacity haulage fleet will materially reduce haulage costs at the mine.

To haul 6500 tons an average of 3 miles, ten 50 ton units are indicated plus two extra for repair and maintenance, making a total of 12 to replace 22 older units. Six more units will probably cost about $300,000.00.

The balance of Fiatt's coal reserves, approximately 9,000,000 tons, lies in the so-called East Field centering at a point 5 miles air line from the Fiatt Tipple, along the T.P. & W. Railway just west of Canton

and the old Eagle Mine and within reach of the "Yard Limits" of Canton.

The East Field in addition to the 9,000,000 tons of reserves has another 9,000,000 virtually surrounded by its acreage with another 3,000,000 tons or more of adjoining potential. Hence the East Field has a potential tonnage reserve of 21,000,000 tons.

The East Field operating conditions will not be as favorable as for the tonnage adjoining the Fiatt Tipple being more nearly comparable to the St. David area of Little Sister which joins on the south and the Cuba reserves of United Electric which likewise joins Little Sister reserves to the west.

Including Little Sister's St. David area and United Electric's Cuba reserves together with other available coal, presents a picture of at least 33,500,000 tons of reserves, about 60% of which lie within a 2 mile radius circle of the location described above, about 80% within a 3 mile circle and only 20% or less requiring a 4 mile haul.

With a foreseeable cost of the East Field substantially more than Fiatt's present cost, certainly it is logical to plan for recovery of this large reserve at the lowest possible cost over new facilities including high capacity mining units and a low cost tipple favorably located.

The suggested location west of the Canton city limits can be served by both the T.P. & W. and C.B. & Q. railroads, which will probably be a requirement.

A rail connection has previously been surveyed from the T.P. & W. tracks to the Fiatt Tipple, should such a connection become desirable for the next 10 years.

Cuba Mine (United Electric)

The Cuba Mine produced 751,575 tons in the same period (12/1/54-11/30/55) working 194 days.

It has an indicated average tipple capacity of 3875

tons per shift. On a 225 day year the indicated annual shift capacity is 872,000 tons.

From available information, Cuba's tipple and preparation costs are somewhat lower than the other mines but their total operating cost is 52¢ a ton higher than at Fiatt.

The mine has a reserve of 7,430,910 tons of relatively high stripping cost coal at about a 4 mile radius haul from the tipple, which at the present rate of production would indicate a life of about 10 years.

There are no other potential reserves available to Cuba other than the Little Sister reserves. Certainly operation of either of Little Sister's reserves, through the Cuba Tipple, would tend to increase rather than decrease operating costs.

There seems no other hope of a substantial reduction in Cuba's costs other than to produce the remaining reserves over a relocated tipple designed for maximum economy and working double shift for greatest efficiency.

It seems logical to consider future operations of the Cuba reserves in conjunction with the East Field for long range planning and greatest economy.

Little Sister Mine

The Little Sister Mine produced 668,319 tons in the 12 month period to 11/30/55 over the St. David Tipple working 173 days.

The indicated average tipple capacity is 3755 tons per shift which would give a maximum of 845,000 tons annually working 225 days single shift.

Coal was produced from two pits, the 550-B operating in the Skyrocket area and the 5561-M with dragline help operating the St. David area.

The Skyrocket area has about 1,100,000 tons in reserve with good pit conditions and an average radius haul of about 2 miles.

This pit should produce good costs and it seems logical to exhaust the reserves over the Buckheart

Tipple. A suitable underpass at the Burlington tracks and State Highway would have future value for right of way for a rail connection from the East Field to the River.

The St. David area joining the East Field of Truax-Traer has heavy pit conditions, a 4 mile radius haul and about 4,250,000 tons in reserve. It appears logical to shut this pit down and work it more economically at some future date in conjunction with the East Field.

Continuing as at present, the combined Little Sister reserves, excluding Cuba, would be exhausted in about 7 years.

Buckheart Mine (United Electric)

The Buckheart Mine produced 1,117,192 tons in the period 12/1/54 to 11/30/55 working 236 days.

It has an indicated average tipple capacity of 4734 tons per shift which at 225 single shift work days would give an annual single shift potential of 1,065,-150 tons. This capacity can be improved either by better daily capacity or working more days.

From presently available figures, Buckheart is operating at a 44¢ per ton higher cost than the Fiatt Mine of Truax-Traer. (See Exhibit I).

Buckheart has rail and dock facilities for river shipments which allows the mine to enjoy about a 30¢ per ton advantage over the other Fulton County mines.

Buckheart has a reserve of 22,380,668 tons and a potential of about 25,000,000 tons of relatively high stripping cost coal, most of it lying within a 4 mile radius haul with the average about 3½ miles straight line from the tipple. At present rates of production this reserve will last about 21 years.

The Buckheart Tipple has had recent improvements added. On a double shift basis, it should produce upwards of 2,400,000 tons which is approximately the combined River tonnage requirement of the three companies.

With an average pit haul of about 4 miles and a shift capacity of 4734 tons, 9 or 10 coal haulers of 50 tons capacity would be required. It would cost about $600,000.00 to modernize the truck fleet.

FULTON COUNTY CONCLUSIONS AND RECOMMENDATIONS

Conclusions

1. There is an unusual opportunity for substantial economic savings as well as physical operating benefits to be derived from a merger of Truax-Traer, United Electric and Little Sister in Fulton County.
2. The combined tonnage of 4,040,936 tons can within a short period of time be comfortably produced over 2 tipples.
3. It would seem entirely possible to bring the Buckheart Tipple up to 5000 tons capacity per shift, if not, more days can be worked all on a double shift basis to produce the 2,500,000 tons required for river shipments.
4. The Cuba stripping equipment should provide the necessary extra strip coal at Buckheart.
5. The Fiatt potential capacity of over 1,500,000 tons on single shift working 235 days almost exactly produces the balance of the Fulton County present requirements. (See Exhibit II). It is possible to work more days for added production.
6. With a total of 76,000,000 tons potential reserve in Fulton County, it becomes highly important to practice the most efficient operating procedures possible together with careful marketing. A fluctuation of 10¢ per ton on either sales realization or operating cost means a gain or loss of $7,600,000 in value.
7. The East Field should be carefully developed for maximum economy in operating costs and market conformity.

8. There are substantial savings to be realized in combined supervision, engineering and administration in Fulton County.

Recommendations

1. Merge the operations and interests of Truax-Traer Coal Company, The United Electric Coal Companies and Little Sister Coal Corporation in Fulton County.
2. Shut down the Cuba Mine and move its stripping equipment to Buckheart.
3. Shut down Little Sister's St. David area and make its stripping equipment available to Fiatt. Process the Skyrocket area coal over the Buckheart Tipple.
4. Double shift and improve capacity and mine costs at Buckheart for full production of River Coal.
5. Operate the Fiatt Mine for full single shift capacity of Fulton County rail requirements.
6. Put in T.P. & W. rail connection to Fiatt if required.
7. Plan a new tipple and site for the mining of the East Field to be ready to replace Fiatt in approximately 10 years, or earlier if market conditions warrant.
8. Modernize and improve costs wherever it is economically possible.
9. Consolidate Fulton County supervision, engineering and administration for best efficiency and economy.

ESTIMATED FULTON COUNTY SAVINGS

1. *Shut Down the Cuba Mine.*

About 86,000 tons of Cuba production moved via Buckheart and the River. This tonnage would be supplied by Buckheart.

Present Buckheart costs are 8¢ a ton lower than Cuba. (Exhibit I).

$.08 x 86,000 $ 6,880.00

A transportation item amounting to $1.03 was charged against Cuba River coal (excluding normal Buckheart River costs).

$1.03 x 86,000	$ 88,775.00

The balance of Cuba's production or about 665,500 tons of all rail coal will be supplied from Fiatt at a 52¢ lower operating cost.

$.52 x 665,500	$346,060.00

Cuba's tipple, track and haulage road maintenance runs over $175,000.00 a year. Assume 40% transferred to Buckheart for second shift operation. 60% of the cost would be saved.

.60 x $175,000.00	$105,000.00

Mine office salaries, supervisory, engineering and general overhead run upwards of $150,000 annually. Assume 35% transferred to Buckheart to handle second shift. 65% would be saved.

.65 x $150,000.00	$ 97,500.00
Total Savings	$644,215.00

2. *Double Shift Buckheart Mine.*

A full double shift operation at Buckheart to produce approximately 2,500,000 tons of River Coal will materially reduce operating costs.

Using Fiatt's unit stripping costs at a 9.26 ratio applied to a 11.57 ratio at Buckheart the stripping cost should average 71.2¢. Allowing a cost of 75¢ against Buckheart's present cost of 90¢. Saving per ton. $ .15

Preparation costs at Buckheart of 42¢ per ton are the highest studied. With the double shift operation and the added maintenance allowance from Cuba above, the cost should be reduced to about 30¢. However, allow 32¢ or a 10¢ per ton savings. .10

Haulage costs are relatively good at Buckheart but on a double shift basis with 50 ton units the cost will be reduced at least 5¢ per ton .05

With the overhead allowance from Cuba and the twice as large divisor due to increased production from double shift production, all general overhead items will be reduced at least 10¢ per ton .10

Total per ton savings $ .40

Such a savings would reduce Buckheart's present cost of $2.77 to $2.37 which is more nearly in line with Fiatt's operating cost of $2.33. Actually on a two shift basis and in spite of a heavier overburden ratio Buckheart should operate more cheaply than Fiatt, with approximately 1,000,000 tons more production.

The 40¢ a ton savings will apply on present Buckheart production of 1,117,192 tons plus the 86,000 tons of river coal from Cuba or a total of about 1,200,000 tons.

$.40 x 1,200,000 $480,000.00

3. *Shut Down Little Sister Operations.*

Of Little Sister's production, 390,000 tons of River coal will be produced at Buckheart at an estimated cost of $2.37 against present costs of $2.44 or 7¢ a ton savings.

$.07 x 390,000 $ 27,300.00

The balance or about 280,000 tons of all rail coal will be produced at Fiatt at an 11¢ lower cost.

$.11 x 280,000 $ 30,800.00

All general office administration and about 10¢ per ton of general overhead will be eliminated:

General office administration	$166,000.00	
10¢ x 668,000 general overhead	66,800.00	
		$232,800.00
Total Little Sister		$290,900.00

4. *Operate Fiatt Mine Full Capacity.*

There is little opportunity for any large savings at Fiatt. The mine now has the lowest cost in the field.

The largest single item of combined savings will be noted under "River Shipments" below.

Haulage costs are high at Fiatt using 20 and 25 ton coal haulers. The full use of a high capacity fleet will reduce costs at least 10¢ per ton. 40 ton units at Fidelity are hauling for 20¢.

$.10 x 1,500,000	$150,000.00

A benefit of 10¢ per ton will accrue on about 700,000 tons of production with the use of one of the large stripping units replacing the 750-B shovel.

$.10 x 700,000	$ 70,000.00
Total Fiatt	$220,000.00

5. *River Shipments.*

The Buckheart Mine which is scheduled to produce all Fulton County River coal reaches barges on the Illinois River at 20¢ per ton. On an explanded double shift basis this figure should improve.

Truax-Traer's River Terminal at Liverpool operates for 11¢ per ton and the rail rate to the river is 40¢ or a total of 51¢ to reach barges from either Little Sister or Fiatt.

Hence a savings of 31¢ a ton will be realized by making these shipments from Buckheart:

Little Sister	391,045 tons
Fiatt Mine	900,309
Total	1,291,345 tons

Use 30¢ savings— $.30 x 1,291,345	$387,400.00

RE-CAP FULTON COUNTY SAVINGS

1.	Shut down Cuba Mine	$ 644,215.00
2.	Double shift Buckheart Mine	480,000.00
3.	Shut down Little Sister Operations	290,900.00
4.	Operate Fiatt full capacity	22,000.00
5.	River shipments	387,400.00
		$2,022,515.00

PERRY COUNTY

The Elkville mines of Truax-Traer, Burning Star Drift (underground) and Burning Star No. 1 (strip) in Jackson County, although operating in the general vicinity of the Perry County mines, are too far distant to be considered for any economic operational savings from a merger.

The Strip mine has reserves of 6,672,149 tons, sufficient to carry it about 12 years at its present rate of production of 564,000 tons. The Drift has reserves for about 27 years.

It is, therefore, logical to consider their operation separately and assume the contribution to the merged company in proportion to the contribution to the parent company—Truax-Traer.

The Perry County mines of Truax-Traer and United Electric produced 2,245,613 tons in the 12 month period December 1, 1954 through November 30, 1955.

The coal was produced over 2 tipples and mined from 3 general operations, Fidelity, Burning Star No. 2 and Pyramid, the tipples being at Fidelity and Pyramid.

The reserves of the two companies total 54,379,389 tons with a potential of 56,000,000 tons all lying within a circle of 3 miles radius centering along the Illinois Central tracks (which divides Truax-Traer and United Electric) near William Creek.

About 30% of the reserve tonnage lies within this same circle at a 2 mile radius.

See Exhibit IV for a clearer picture of reserves and mining operations.

Pyramid Mine (Truax-Traer)

The Pyramid Mine is operating on property adjacent to the Pyramid Tipple. Pyramid has a small reserve of coal, which will be exhausted at the present rate of production in less than two years.

The Stripping unit is an 1150-B Dragline which normally will be moved to Burning Star No. 2 mine in a short time.

Burning Star No. 2 is now shipping coal to the Pyramid Tipple for preparation at about a 25¢ per ton penalty.

A prompt decision must be made as to a new tipple and tipple site to be ready to operate not later than the Fall of 1957.

Burning Star No. 2 Mine (Truax-Traer)

Burning Star No. 2 and Pyramid combined produced in the 12 month period 1,167,066 tons.

Burning Star No. 2 is presently shipping its tonnage to the Pyramid Cleaning Plant at a freight and dumping charge of 25¢ per ton. In spite of this handicap it is producing coal at a considerably less cost than the other two mines.

The mine has a coal reserve of 30,685,842 tons with a potential reserve exceeding 32,000,000 tons giving a life of over 27 years at present rates of combined production. (Pyramid and Burning Star No. 2).

Pyramid and Burning Star No. 2 are operating with a total of 17 coal trucks. A savings can be realized on a combined operation with the use of 50 ton coal haulers.

The primary stripping unit at Burning Star No. 2 is a 950-B stripping shovel.

Fidelity Mine (United Electric)

The Fidelity Mine produced 1,078,547 tons in the 12 month period (12/1/54 to 11/30/55) working 217 days.

The indicated tipple capacity is 4970 tons per shift which gives a potential annual production, working 225 days, of 1,118,250 tons.

The Fidelity Tipple is probably one of the oldest in the area but has been improved. Its present operating cost is 34¢ or 8¢ a ton higher than the Pyramid Tipple cost.

Haulage costs are good, both at Fidelity and Burning Star No. 2, when compared with Fulton County costs.

Fidelity's operating costs are 50¢ a ton higher than the combined Pyramid and Burning Star No. 2 costs.

The Fidelity Mine has a reserve tonnage of 23,693,547 tons with a potential of about 24,000,000 tons. Practically all of this reserve lies at a greater distance from the present tipple than the present haul of 3½ and 4½ miles. It takes a 5 mile radius to include all the reserves.

The stripping units at this mine are a 45 cu.yd. Shovel, a 35 cu.yd. Dragline and a recently added Wheel Excavator. Sixteen 40 ton coal trucks are used for haulage.

Perry County Conclusions

1. There is an excellent opportunity for operational savings and advantages in merged interests of Truax-Traer and United Electric in Perry County.
2. Truax-Traer is faced with an immediate decision and capital expenditures for a new tipple and tipple location.
3. Present Truax-Traer operations are substantially cheaper (50¢ per ton) in Perry County than United Electric.
4. The Fidelity Mine is faced with increasing costs due to gradually increasing haulage distances.
5. Combined production requirements can be handled comfortably through a double shift tipple of 3000 tons capacity per shift.
6. A modern tipple, streamlined for present and indicated future market requirements can prepare the coal cheaper than present tipples.
7. Haulage can be improved and shortened on a combined total reserve of over 56,000,000 tons.
8. With a reserve of this magnitude every effort must be made for economical operations, sales, administration, etc. Every fluctuation or change in either cost per ton or realization of

10¢ per ton means a change of $5,600,000.00 in value.

9. There are substantial savings to be realized from combined supervision, engineering, clerical and administration in Perry County.

Recommendations

1. Immediately engineer and plan a new tipple of about 5000 tons capacity per shift, located near the center of the combined 56,000,000 ton reserve.
2. Connect with both the Illinois Central and Missouri Pacific railroads.
3. Shut down both the Fidelity and Pyramid Tipples.
4. Move the Pyramid 1150-B to Burning Star No. 2.
5. Modernize all haulage equipment.
6. Centralize all operational functions.
7. Combine supervision, engineering, clerical and administration.
8. And, outside the scope of this report, conceive some scheme of economically reaching the river for an added outlet of production.

ESTIMATED PERRY COUNTY SAVINGS

1. *Central Modern Tipple*

A fully modern efficient plant streamlined for present day preparation demands without heat drying should produce coal for less than 20¢ per ton. Dual shifting will further reduce the cost per ton. A conservative figure would be about 18¢ per ton.

The new tipple would, therefore, save 8¢ per ton on Pyramid's cost of 26¢ and 16¢ per ton on Fidelity's cost of 34¢.

$.08 x 1,167,066	$ 93,565.00
$.16 x 1,078,547	$172,565.00

The Central Tipple will eliminate the 25¢ shiping and handling charge from Burning Star No. 2 to the Pyramid Tipple. The tonnage will include Pyramid's tonnage in about a year's time.

$.25 x 1,167,066	$321,765.00

Maintenance is running upwards of $180,000 a year at Fidelity on tipple and yard tracks, with Pyramid about the same.

A new modern tipple and yard will maintain for that figure, hence saving the full item. $180,000.00

Total Tipple $737,695.00

2. *Modernize Haulage Equipment*

The installation of 50 ton haulage units to replace the present 20 and 35 ton units at Pyramid and Burning Star will reduce haulage costs about 5¢ a ton on the present 18¢ cost. The resulting figure of 13¢ can be taken for the combined tonnage of both companies over a short haul to the new Central Tipple.

Although Fidelity is now using 40 ton units their cost is 8¢ a ton higher than at Pyramid and Burning Star No. 2. A shorter haul and modern units will correct the cost. Hense, the savings will be:

(.18-.13) $.05 x 1,167,066	$ 58,350.00
(.20-.13) $.07 x 1,078,547	$ 75,500.00
Total Haulage	$133,850.00

3. *Centralize Operating Facilities*

Central facilities and combined administration, supervision, engineering and general overhead will result in substantial savings.

A central shop and repair facilities will conservatively save $ 75,000.00

General overhead, supervision, etc., are running upwards of $175,000.00 at Fidelity and about the same at the Truax mines. 65% of one of the operations can be saved, transferring 35% of .65 x 175,000.00 $113,750.00

the expense to the combined operation.

Total Centralization $188,750.00

4. *Stripping*

There is entirely too much spread between Burning Star No. 2 stripping costs of *64¢* and Fidelity's cost at $1.01. United Electric has forecast a possible *75¢* cost at Fidelity. However, using Burning Star's unit cost at 7 to 1 ratio against a ratio of 10 to 1 at Fidelity, the cost should be about 90¢ on a comparable basis. Hence there should be at least a 11¢ savings on 1,078,547 tons $118,640.00

5. *Re-Cap Perry County Savings*

1. Central modern tipple	$ 737,695.00
2. Modernize haulage equipment	133,850.00
3. Centralize operating facilities	188,750.00
4. Stripping	118,640.00
Total Perry County	$1,178,935.00

RE-CAP FULTON AND PERRY COUNTY SAVINGS

Total Fulton County	$2,022,515.00
Total Perry County	1,178,935.00
Total Illinois Operational Savings	$3,201,450.00

PART IV

SELLING AND ADMINISTRATION

Selling

Both companies maintain sales coverage of the market areas served by Illinois coals. There is a complete duplication not only of expense but of sales effort.

Such sales efforts conscientiously and diligently pursued have an adverse effect on market prices.

Principal markets for Illinois coals are the industrial and utility demands. Supplying such customers usually runs to rather large contracts carrying a uniform shipping schedule. It is a distinct advantage to both the customer and supplier to have a large backlog of reserves as well as to have several mines able to back up shipping schedules in the event of mishap or forced shut down of any one operation.

Further, operating as separate companies, there is undoubtedly considerable sub-standard business taken in order to fill out operational tonnage volume. This has an adverse effect on realization even though operating costs may be maintained. Merged operations would eliminate to a large extent the necessity of booking such business unless economically sound.

Sales, policies, advertising and administration can all be consolidated with definite dollar savings, at the same time giving more effective and efficient service and coverage to customers.

It would be difficult without a detailed study of both companies' sales organiaztions, their outlying offices and a study of an organization chart for merged sales coverage, to more than estimate in a general way the indicated savings possible.

Administrative

Both companies maintain almost parallel administrative, financial and clerical staffs. It is safe to say that with modest additions to either organization the combined work load can be efficiently handled.

In a combination of forces the most competent talent and best practices of both companies can be used for the benefit of the merged company.

Indicated reductions and payroll savings will not all be possible promptly due to personnel of long service on or due soon for pension benefits. However, over a period of time the indicated economies will adjust.

Financial

Without question, as in previous mergers or consolidations, there will be many opportunities for tax savings, write-offs and more efficient use of funds and credit.

No attempt will be made to estimate such benefits as it is a separate study requiring full and complete information.

Estimated Savings

1. *Sales and Administration*

The United Electric's "Selling, General and Administrative Expenses" for the year ending November 30, 1955, totalled $1,020,081.00 for 3,375,529 tons of production or 30¢ per ton.

Truax-Traer's cost for the same period was $1,733,659.00 for 7,516,857 tons of production or 23¢ per ton.

The combined tonnage of the two companies was 10,892,386 tons and the combined cost was $2,753,740.00.

Allowing for about 40% or $400,000.00 of United Electric's cost to be added to the Truax cost to handle the combined tonnage, a total of $2,133,659.00 would result or 19.6¢ per ton. Use conservatively 20¢.

Present total cost	$2,753,740.00	
20¢ x 10,892,386	2,178,500.00	
Savings		$575,240.00

2. *Market Stability*

The combined sales effort and advantages will result in an increase in realization over a relatively short period.

In addition elimination of the necessity of bookkeeping sub-standard business will substantially improve realization.

Both factors will conservatively increase realization over a short period of time by at least 10¢ per ton. With a combined Illinois tonnage of over 7,300,000 tons the resultant savings will be at least $730,000.00

Total Estimated Sales, Administration and General Savings $1,305,240.00

Estimated Total Savings (Operating, Sales, Administration)

From Combined Illinois Operations	$3,201,450.00
From Combined Sales, Administration, etc.	1,305,240.00
Total	$4,506,690.00

PART V

CAPITAL EXPENDITURES

From the foregoing report, considerable operating savings are indicated from the merger being considered.

Certain capital investments will necessarily have to be made to accomplish the results forecast.

Although no detailed engineering studies have been made, it is possible to give an approximate idea of expected expenditures and it seems logical to include such an estimate at this time. It will be understood that any estimates made will be subject to correction as more definite engineering information is obtained.

Estimate of Major Expenditures Required

Fulton County

1. *Move Cuba Shovel and Wheel Excavator to Buckheart.*

The airline distance between the Cuba and Buckheart Pits is about 7 miles—allow 9 miles travel.

Most of the distance will be over jointly owned property. Little Sister haulage roads may be of great help in selecting a route and speeding up the move. The C. B. & Q. tracks and Highway 73 will be a critical crossing.

Very little additional right of way will be required. All calculations have been made separately and not included in the report. The work sheets are available if required.

	Operating Expense	Capital
Estimated cost	$ 75,000.00	
Move other required equipment	10,000.00	
(Operating Expense)	$ 85,000.00	

2. *Double Shift Buckheart Mine*

Several miles of main haulage road will be required for opening a new pit. Allow (Operating Exp.) $ 30,000.00

	Operating Expense	Capital
New main power lines will have to be established. Considerable line material and transformers can be salvaged from Cuba.		
Allow (Capital Expense)		$ 25,000.00
Present tipple capacity is indicated at 4734 tons per shift. The tipple should produce 5500 tons per shift.		
Increased capacity would be preferable over a tight operating schedule. Allow for increasing capacity (Capital Expense)		300,000.00
For an average main haul of 3 miles, 9 trucks of 50 tons capacity will just about haul 5500 tons per shift. Allow 2 trucks for maintenance and repair. 11 fifty ton coal haulers would be quite safe at about $50,000.00 each.		
Allow—$550,000.00		
Estimated salvage from 27 trucks now being used at the two mines of an average of $6,500.00 each or about:		
Credit — $175,000.00		
Net cost new fleet (Capital expense)		375,000.00
The River Dock will probably need some improvements for capacity, economy and double shift operation. Allow $50,000.00 or about the cost of extending the railroad to the Truax Dock (Capital Expense)		50,000.00

3. *Fiatt Mine*

Improve haulage equipment. Fiatt now has 6 new 45 ton caterpillar coal haulers. To haul up to 7000 tons per shift, 11 trucks will be required. Allow 2 for repair and maintenance gives a total of 13 or 7 more to be acquired.		
7 at $50,000.00 — $350,000.00		
Fiatt now has 7 — 25 ton units and 15 — 20 units. Allow salvage of —		
15 - 20 ton at $ 3,000 — $ 45,000.00 7 - 25 ton at $10,000 — 70,000.00		
$115,000.00		
Net new truck fleet (Capital Expense)		$235,000.00

	Operating Expense	Capital
Utilize Little Sister's 5561—40 cu. yd. shovel. Will require a move of either 5561 to north field or 5561 to 950-B pit and 950-B move to north field. In either case dead-head distance of about 5 miles entirely over owned property. Critical crossings are T. P. & W. Railway and Highway No. 9.		
Estimated cost of moves (Operating Expense)	$ 25,000.00	
Total Fulton County Operation, Expense	$140,000.00	
Total Fulton County Capital Expense		$985,000.00

In addition, about 8 years from now a new tipple will have to be built near the old Eagle Mine west of Canton. It will probably require $1,800,000.00 to $2,000,000.00. However, such a new tipple would be required in any event.

Perry County

Central Tipple Double Shift.

Estimated cost of a modern 5000-6000 ton per shift tipple streamlined for utility and industrial markets.		
(Capital Expense)		$1,800,000.00
About 5 to 6 miles of yard track and connecting spurs.		
(Capital Expense)		250,000.00
Centrally located shop and other facilities—salvaging from present operations.		
(Capital Expense)		150,000.00
New main line haulage roads.		
(Operating Expense)	$40,000.00	
Modernize truck fleet — 10 units at $50,000.00	$500,000.00	
Salvage—		
Fidelity 15-40 ton units at	$10,000.00	
	$150,000.00	
Pyramid & Burning Star No. 2—9-20 ton units at $3000.00	27,000.00	
7-25 ton units at 10,000.00	70,000.00	
Total Salvage	$247,000.00	

	Operating Expense	Capital
Net Total New Truck Fleet (Capital Expense)		$ 253,000.00
Move 1150-B to Burning Star No. 2. This will be done over about a 5 mile route previously used.		
Estimated Cost (Operating Expense)	$ 18,000.00	
Total Perry County Operating Expense	$ 58,000.00	
Total Perry County Capital Expense		$2,453,000.00

RE-CAP CAPITAL EXPENDITURES FULTON AND PERRY COUNTIES

Fulton County	$140,000.00	$ 985,000.00
Perry County	58,000.00	2,453,000.00
Totals	$198,000.00	$3,438,000.00

Against this figure will be salvage of the Pyramid, Fidelity and Cuba Tipples; also St. David Tipple of Little Sister in about 2 years. Such salvage will reduce the capital investment to a figure below $3,000,000.

This means that the investment will be amortized in less than one year by the estimated saving.

Set up as a depreciation, it will average less than $300,000.00 a year or approximately 6.7% of the savings forecast.

Of the above total capital expenditure, Truax-Traer would normally be required to make the following investments in any event:

Fiatt

New trucks	$ 235,000.00

Perry County

New Tipple		1,800,000.00
New trackage		150,000.00
Central Facilities		100,000.00
Truck Fleet for Single Shift		
Cost	$500,000	
Salvage	97,000	403,000.00
Total		$2,688,000.00

	Operating Expense	Capital
Hence to the merged companies the additional capital investment would be:		
Merged Capital Investment Estimated	$3,438,000.00	
Truax-Traer Investment Estimated	2,688,000.00	
Difference	$ 750,000.00	

Salvage of the three tipples would just about wipe out the difference.

KOLBE DEPOSITION EXHIBIT L

THE UNITED ELECTRIC COAL COMPANIES

307 North Michigan Avenue
Chicago 1, Illinois

September 12, 1960

Mr. Frank Nugent, President
Freeman Coal Mining Corporation
300 West Washington Street
Chicago 6, Illinois

Dear Frank:

Enclosed is copy of letter from Roy Miller of Alcoa which I thought you would like to see.

In line with our recent discussion, it appears worth while to make a study of possible investment and cost per ton that might be achieved in an underground mine on the coal acreage that has been acquired by the Aluminum Company.

There is, of course, no hurry about this but whenever you would like to do it, please let us know what information is needed and we will supply it.

With kindest regards,

Yours very truly,

/s/ Johnnie

JMM:EW

KOLBE DEPOSITION EXHIBIT N

October 3, 1955

Mr. R. J. Hepburn:

In regard to the North Canton Field, I have a date today with Mrs. Lillian Miller who owns 220 acres adjoining our Lynch property and her attorney and I are hopeful of winding this up fairly soon.

Three properties that we need to drill in this area are the Miller 220, Williams 231 and Houston 256 as this is where we are meeting strong competition from Ayrshire. Mrs. Williams, if she deals with anyone, will deal with us, and Don Houston, the President of the bank in Canton, is interested only in a trade and will give us an opportunity before he will Ayrshire. This will run into money and if we can keep Ayrshire from getting it I think for the time being I think we should let it remain in that state. The other properties in the vicinity are owned by Mrs. Biddie Ingersoll who at present will deal with neither of us on any portion of her 1000 acres and Mr. and Mrs. Fred Strawn, who own 320 acres that we need to drill, are about 75 years of age and will deal with no one at all but Mrs. Strawn has talked with her heirs and told them they should let us have it after they come into possession.

These tracts are in the eastern part of our North Canton Field and it is only here that we have had opposition. The west area, in which we own or control 868 acres, has had no competition. There are, however, several hundred acres that should be picked up but this will be a matter of attrition as none of the land owners want to sell at any price. We have been attempting to deal with these people for several years and it is a time consuming process. William Blakely, who is now retired and previously operated the Blakely Coal Company and was in the mining business for many years, lives on the hard road north of Canton right on the edge of the west part of our field. He is financially independent but wants some-

thing to do to occupy his time. He has done me several favors in the past out there and would like to work for us taking up options. I think this could be arranged either on a salary or a commission basis, and I believe he would be a valuable man to have. He knows every piece of coal in the county and is very well acquainted with and respected by the land owners and I would like to have you meet him and talk over the proposition. We have lost heavily in the past to competitors in Fulton County and it shouldn't happen again.

As you know we have competition in all of this area, from one source, and in the north are from two. Most of these people are amenable to talking, for two reasons; they know that if they have strippable coal they are going to have to sell eventually, and to meet the price appeals during this time of low farm income.

While we have too little definite information as to the reserves in the area, there is undoubtedly enough to keep a mine going for many years to come. No. 6 coal, we know is present over much of it, and No. 5 should be present in a larger part. Depth remains to be ascertained. There are a total of about 18,000 acres in the area under discussion. Should one third contain coal at 5,000 tons per acre this would yield 30,000,000 tons, and it could be greater.

Peabody, Truax-Traer, Ayrshire, Southwestern and Midland (together), all have reserves substantially greater than ours, and reserves are extremely difficult to find now that all the major fields are gone. I have kept out of this area since Feb. 10, and if you wish me to back out completely, I will advise these people that we are no longer interested. However, I should like to go back in immediately.

W. H. Latimer

KOLBE DEPOSITION
EXHIBIT 8

Patented July 27, 1943

2,325,064

UNITED STATES PATENT OFFICE

[illegible]

EXPLOSIVE COMPOSITION

Robert W. Lawrence, Wilmington, Del., assignor to Hercules Powder Company, Wilmington, Del., a corporation of Delaware

No Drawing. Application June 22, 1940, Serial No. 341,340

8 Claims. (Cl. 52—11)

This invention relates to explosive compositions of improved power and safety and more particularly to explosive compositions containing a liquid sensitizing agent which is insensitive to impact, and to explosive compositions which do not contain liquid explosives sensitive to friction.

Explosive compositions which have been used by the prior art have normally been divided into two classes: first, sensitive explosives which contain nitroglycerin or admixtures of nitroglycerin with other nitric esters which are sensitive to impact, and explosive compositions containing no explosive constituent which is sensitive to impact. The art has found the use of nitroglycerin explosives extremely useful in blasting operations. However, for a number of operations, it is preferable to use explosives that are relatively insensitive to detonation and are completely or almost completely insensitive to impact and to friction. The insensitive explosives usually comprise an explosive salt such as ammonium nitrate in admixture with other salts such as sodium or potassium nitrate and carbonaceous materials such as wood pulp, starch, ivory meal and similar substances together with a sensitizer such as dinitrotoluene, trinitrotoluene, or other materials that are insensitive to impact. These types of explosives are used in many operations where it is especially desirable to eliminate the hazards encountered by the use of sensitive explosives.

It is an object of this invention to provide an explosive which is relatively safe to handle. A further object of this invention is to provide an explosive insensitive to impact but which may be detonated with a commercial blasting cap. A further object of this invention is to provide an explosive composition that does not contain a liquid explosive sensitive to impact or friction.

A further object of this invention is to provide an explosive composition that is relatively safe during packing operations and during the loading of bore holes. A further object of this invention is to provide an explosive which is insensitive to impact and which is cap insensitive. Another object of this invention is to provide an explosive composition that contains a liquid nitroparaffin as the sensitizing agent. Other objects will become apparent hereinafter.

In general, the objects of this invention are accomplished by compounding an explosive composition which contains an admixture of oxidizing salts, such as, for example, ammonium, sodium or potassium nitrate; with a reducing or carbonaceous material, such as, for example, wood flour, ivory meal, bran or legume, meal and the like; and a liquid nitroparaffin, such as, for example, nitromethane, nitroethane, dinitropropane, dinitropropane or other liquid nitroparaffins which has an oxygen balance not less than about —50%.

The manufacture of explosives of this invention is carried out in any of the various manners well known in the art, and may include, for example, a procedure comprising the screening into a mixer, such as a Tulley mixer, an amount of an oxidizing salt, such as sodium, potassium or ammonium nitrate, alone or in admixture with one another along with an amount of carbonaceous or reducing material, such as wood flour, bran, legume, etc. The Tulley mixer bowl contains the desired amount of a liquid nitroparaffin alone or mixed with other nitroparaffins to obtain a mixture of the desired oxygen balance and sensitivity. The Tulley mixer after the ingredients are thoroughly mixed is dumped and the explosive composition packed into casual cartridges that may be manufactured from paper, plastic or metal. The cartridges may be of any convenient diameter, but normally will have a diameter greater than about 2 inches as the type explosives of this invention are generally found most useful in quarrying rock or in large operations where the large diameter cartridges are desired.

The liquid nitroparaffins in themselves are not explosives; i. e., they will not detonate with a commercial blasting cap. However, balanced explosive compositions containing liquid nitroparaffins produce a quantity of explosive energy approaching that of explosive compositions containing the same percentage of nitroglycerin. The oxygen balance of the nitroparaffins is very low, and, therefore, care in compounding an explosive composition must be exercised so, if the oxygen balance of the final explosive composition is too low, difficulty in effecting detonation is experienced. Thus, for example, nitromethane has an oxygen balance of —39.3%; nitroethane, an oxygen balance of —69%; dinitroethane, an oxygen balance of —39.9%; and dinitropropane, an oxygen balance of —49.7%. The liquid nitroparaffins having a similar proportion of oxygen than nitroethane have such low oxygen balances that they preferably are not to be used alone in explosives, but they may find use in conjunction with the lower nitroparaffins. For example, suitable mixtures may include a solution containing two parts of nitroethane and one part of nitrobutane by weight with an oxygen

balance of —81% or a solution containing equal parts by weight of nitromethane and nitropropane with an oxygen balance of —87%. Therefore, my invention does not contemplate the use of nitroparaffins or mixtures of nitroparaffins having an oxygen balance lower than —100% alone in explosive compositions.

As a specific example of carrying out my invention, I may admix 69 parts by weight of ammonium nitrate with 29 parts by weight of nitromethane and two parts by weight of balsa pulp. The admixture after thorough incorporation is packed into cartridges, and is sensitive to detonation by a No. 6 blasting cap and is found to be a very desirable explosive. Further, the same mixture when tested by the "halved cartridge method of propagation" will cause detonation across a gap as great as 10 inches. It is believed that the nitromethane causes detonation of the composition by interreaction with the oxidizing materials, especially the ammonium nitrate. The reaction may be initiated by a blasting cap but not by an impact and thus provides for the production of a very safe but cap sensitive explosive composition. However, this theory is not to be construed as limiting this invention.

A further advantage of the above type explosive over the nitroglycerin containing explosive composition is that nitromethane does not cause the operators to develop headaches when the explosives are handled; and, further, by itself it will not freeze above —15° F. so that when a composition containing nitromethane is used in normal operations, freezing can not occur until this temperature is reached, and often will not occur until a much lower temperature is reached. If freezing of a nitromethane powder occurs, the effect is not as hazardous as the freezing of nitroglycerin powders since the explosive is much less sensitive to thawing operations. Furthermore, the freezing point can readily be lowered by addition of suitable proportions of other liquid nitroparaffins.

In order to point out the invention more specifically, the following examples are given of explosive compositions containing liquid nitroparaffins in varying proportions as the sensitizing ingredients. The compositions of a number of explosives are given in Table 1, and their various properties are listed.

Table 1

	Sample			
	A	B	C	D
Nitromethane ..... per cent	5.0	10.0	40.0	20.0
Ammonium nitrate ..... do	95.0	74.0		60.0
Sodium nitrate ..... do			48.0	
Wood flour ..... do		6.0	12.0	
Coal ..... do	4.0			
Balsa ..... do				4.0
	100.0	100.0	100.0	100.0
Oxygen balance (ingredients) ..... per cent	+4.0	−1.5	−19.2	−4.0
Count, 1¼ x 8"/250	147	150	146	118
Sensitiveness [1]	10"	9"	10"	9"
Detonation rate ..... m./sec.		3,200	3,100	3,000
Sensitiveness to impact [2] ..... cm.		7 100	7 100	7 100
Sensitiveness to rifle bullet [3]	(4)	(5)	(5)	(5)

[1] Tested on impact machine, 2 kg. falling weight; P=partial shot in steel cracking.
[2] Tested by impact of 30-06 bullet from U. S. Army rifle at 120 yards.
[3] When primed with a No. 6 blasting cap.
[4] Not tested.
[5] Did not shoot.

Other cap sensitive explosive compositions may be prepared in which the nitromethane is replaced by dinitroethane or dinitropropane.

It has been found that other explosive compositions may be prepared, with nitroparaffins, which are not sensitive to detonation by a commercial blasting cap but are sensitive to detonation by a booster charge. Thus, for example, it is possible to produce an explosive composition which furnishes a high amount of power when it detonates, but which is so insensitive that a booster, such as a half stick of 40% dynamite or a charge of dinitrotoluene or tetryl must be used to prime the composition. In general, this type of insensitive explosive composition is prepared by decreasing the percent of the nitroparaffin present or by using a nitroparaffin having a lower oxygen balance or by combining these two features.

To illustrate the type of explosive compositions which are compounded to be insensitive to detonation by a commercial blasting cap, Table 2 is given wherein the composition and properties of an extra and straight dynamite are listed.

Table 2

Sample	A	B
Nitroethane	Per cent 12.0	Per cent 20
Ammonium nitrate	74.0	
Sodium nitrate	8.0	66.5
Balsa	6.0	6.5
	100.0	100.0
Oxygen balance (ingredients)	−3.0	−6.0
Count, 1¼ x 8"/250	110	232
Sensitiveness:		
Primed with No. 6 cap	Failed	Failed
Primed with ½ stick 5×8 dynamite	Shot	Shot

To illustrate gelatin type dynamites containing nitroparaffin, Table 3 is given wherein the composition and properties of a gelatin explosive are listed.

Table 3

Sample	A
Nitromethane	Per cent 12.0
Nitroglycerin	1.20
Sodium nitrate	67.0
Wood flour	5.37
	100.0
Oxygen balance (ingredients) ..... per cent	−2.7
Count, 1¼ x 8"/250	92
Sensitiveness:	
Primed with No. 6 cap	Failed
Primed with ½ stick 5×8 dynamite	Shot
Weight strength ..... per cent	68.3

[1] Determined with ballistic mortar.

It will be understood by those skilled in the art that similar explosive compositions may be prepared by using mixtures of nitromethane with the higher nitroparaffins such as nitropropane and nitrobutane, and that the sensitiveness of such explosive compositions may be controlled by varying the composition of the nitroparaffin mixtures as, for example, by altering the nitromethane and nitroethane content.

It has been found that the explosives containing nitroparaffins such as nitromethane, nitroethane and the like are advantageous because they are highly insensitive to impact and friction and in consequence are especially adapted for packing into metal cans. These nitroparaffin explosive compositions that are cap sensitive may

be manufactured and packed with automatic machinery into a metal can without the danger which this type of operation entails when nitroglycerin containing explosive compositions which are sensitive to impact and friction are manufactured and packed with automatic machinery.

The advantages of the nitroparaffin explosives over the known explosive compositions are insensitivity to impact, lack of causing headaches, and low freezing points, while still being capable of being manufactured to any degree of cap sensitivity.

The explosives of this invention have been found to be highly desirable in all blasting operations when packed in the desired size and type containers. The preferred use, however, is in large operations such as open pit mining and quarry blasting, where the explosive compositions may be used in large diameter cartridges of metal, paper or plastic.

The term "oxygen balance" used in the specification and claims is well known and accepted by the art. The "oxygen balance" of an explosive compound is calculated by determining the total weight of the compound and dividing this weight into the difference between the weight of the oxygen required to completely oxidize the elements of the compound and the weight of the oxygen actually present in the compound.

The "halved cartridge gap method" is a standard explosive composition test and is described fully in Bulletin 348 issued by the U. S. Bureau of Mines.

It will be understood that the details and examples hereinbefore set forth are illustrative only, and that the invention as broadly described and claimed is in no way limited thereby.

What I claim and desire to protect by Letters Patent is:

1. An explosive composition comprising an oxygen deficient liquid nitroparaffin containing not more than two nitro groups and having an oxygen balance in excess of about —100% in admixture with an oxidizing salt and a carbonaceous material.

2. An explosive composition comprising an oxygen deficient liquid nitroparaffin containing not more than two nitro groups and having an oxygen balance in excess of about —100% in admixture with ammonium nitrate and a carbonaceous material.

3. An explosive composition comprising nitromethane having an oxygen balance in excess of about —100% in admixture with an oxidizing salt and a carbonaceous material.

4. An explosive composition comprising nitroethane having an oxygen balance in excess of about —100% in admixture with an oxidizing salt and a carbonaceous material.

5. An explosive composition comprising between about 5% and about 45% of nitromethane having an oxygen balance in excess of about —100% in admixture with an inorganic nitrate and a carbonaceous material.

6. An explosive composition comprising between about 15% and about 25% of nitroethane having an oxygen balance in excess of about —100% in admixture with an inorganic nitrate and a carbonaceous material.

ROBERT W. LAWRENCE.

KOLBE DEPOSITION EXHIBIT T

HERCULES POWDER COMPANY
INCORPORATED

June 27, 1956

The United Electric Coal Companies
307 North Michigan Avenue
Chicago 1, Illinois

Attention: Mr. Frank F. Kolbe, President

Gentlemen:

Reference is made to the license agreement of May 1, 1956, entered into by Hercules Powder Company and The United Electric Coal Companies covering Hercules' United States Letters Patent No. 2,325,064 relating to explosive compositions. Among other things, the reference license agreement provides for the payment of royalties at the rate of three-quarters of one cent ($0.0075) for each pound of explosive composition covered by the claims of the patent. You have requested that Hercules Powder Company waive the royalty payments provided for in the license agreement of May 1, 1956, in consideration of The United Electric Coal Companies making available to Hercules for its use the results of the research and development work conducted by Mr. Frank F. Kolbe with respect to the use of the explosive compositions covered by United States Letters Patent No. 2,325,064.

Hercules Powder Company hereby waives the royalty payment of three-quarters of one cent per pound of explosive composition resulting from the practice of the inventions claimed in United States Letters Patent No. 2,325,064 made and used by you, which would become due under the reference license agreement, so long as Mr. Frank F. Kolbe continues the development and experimental work in the practical application and use of explosive compositions covered by United States Letters Patent No. 2,325,064 at the facilities of The United

Electric Coal Companies, and so long as you make available to Hercules for its unlimited use written reports of such development and experimental work, and so long as you permit authorized representatives of Hercules Powder Company, at Hercules' election, to visit your plants and observe such development and experimental work. You further agree to grant and do hereby grant to Hercules an irrevocable, non-exclusive, royalty-free license, with the right to grant sublicenses without accounting to you, under any invention first conceived or reduced to practice by you in the performance of the development and experimental work contemplated by this agreement, but such license shall be limited to those inventions conceived or reduced to practice while this letter agreement is in effect.

Either party to this letter agreement may terminate the same upon ten (10) days' written notice to the other party. Upon termination of this letter agreement the waiver of royalty payments under the license agreement of May 1, 1956, as herein provided, shall terminate and all royalties provided for in the license agreement shall thereafter accrue and shall be due and payable by United Electric Coal Companies to Hercules Powder Company in accordance with the terms of that agreement.

If the foregoing conditions as to the waiver of royalty payments are acceptable to you, please indicate your acceptance thereof by signing and returning one copy of this letter to us for our files.

Very truly yours,

HERCULES POWDER COMPANY
By /s/ [Illegible]

KOLBE DEPOSITION EXHIBIT W-1

February 25, 1958

Mr. Harry La Viers, President
South-East Coal Company
Paintsville, Kentucky

Dear Harry:

We have a mining operation in West Kentucky that produces a high grade coal selling on the average for $6.25. After we get the coal uncovered, it costs us about $2.50 to transport the coal to the washing plant, wash it, pay royalties, and pay selling and administration expenses.

At our present location, we are running into deeper overburden and therefore have been considering an underground operation.

The coal averages 42 inches and has a good roof and a fair bottom. It is somewhat rolling. The high wall is in good condition.

Do you know of anyone with equipment who would care to come in and mine this coal at a price that would give him and us a profit?

Very sincerely yours,

President

Dear Frank:

This letter is in reply to yours of February 25th with reference to some possibility of underground mining on your properties in West Kentucky and to tell you that right at the moment I am sorry I can't be helpful.

I hope you are planning on coming to Boca Raton to the next meeting of the Coal Executives so that I can discuss this matter with you personally and see if I can't come up with some suggestion. If you do not attend the Florida meeting, I will be in Chicago before too long, I think, and will drop in and visit with you for a while.

Yours truly,

December 3, 1957

Memorandum to: Mr. Robert J. Hepburn

In reply to your memorandum of November 29 regarding deep coal in southern Illinois, I think for the present we can employ our money better other places.

President

KOLBE DEPOSITION EXHIBIT X-1

November 29, 1957

Mr. F. F. Kolbe:

I am attaching copy of a letter from Tom and a map showing the deep coal that was brought to our attention by Bill McCulloch of Roberts & Schaefer.

If I am informed correctly, I would estimate that this No. 6 coal would run around 3% sulphur. However, the ash and Btu should be better than our DuQuoin coal. Of course this does not compare with the 1% ash that Old Ben have under control. It may be that if we would not be interested in deep coal of this type we might be able to offer it to the aluminum company.

I would appreciate your advising me what you think of deep coal of this type.

KOLBE DEPOSITION EXHIBIT X-2

November 25th
1957

Mr. R. J. Hepburn

Bill McCulloch was in the office this morning discussing the 4 blocks of coal he is trying to dispose of in Franklin County. These consist of the following:

Block #1, 2194.45 acres owned by Franklin County Mining Company in north and east of Benton. This should contain at least 14,000,000 tons of recoverable #6 coal, running from 7′ to 8′ in thickness at a depth of about 600′. It may be that the fact that some of this is under the City, the reserve will have to be cut considerably. This coal is adjoined on the west by the holdings of Old Ben and on the south by the Freeman Coal Company. The entire eastern boundary adjoins the U. S. Steel Company holdings. While the territory to the West is open, and the holdings could be extended, the majority of the reserve could be mined by Old Ben. Their mine #14 probably is within 2 miles of the western edge. About 2,800,000 tons could be mined from a new opening of the Freeman Coal Company, which is about 1¾ miles from the southern edge. The field is served by the C. & E.I., Mopac and the Eldorado branch of the I. C. At the closest point, Big Muddy River is about 2 miles away.

Block #2 consists of something over 1100 acres or 7,700,000 tons of recoverable #6 coal about 700′ deep and lies west of Blocks 3 and 4. This is bound on the north by Freeman, on the west by Peabody's abandoned mine #18, which still has some reserve, and on the south Old Ben's mine #9, whose location is probably between 2 and 3 miles away. The Eldorado branch of the I. C. cuts through this area. It is 7 miles away from the Big Muddy.

Block #3 consists of 660 acres of scattered holdings of the Burr Oak Coal Company, which lies between blocks 2 and 4.

Block #4 consists of 5,025 acres or probably 35,000,000 tons of recoverable #6 coal from 6′10″ to 8′7″ thick at

a depth of 700', owned by Franklin County Coal Corporation. This is on the Edgewood cutoff of the I. C. and close to the Eldorado branch. It is about 15 miles from the Big Muddy.

I pointed out above that Block #1 could be valuable to Old Ben and Freeman, but Blocks 2, 3 & 4, if filled in by the acquisition of coal owned locally by individuals, would contain approximately 12,620 acres or at least 88,340,000 tons of recoverable #6 coal, as there is approximately 153,000,000 tons in place. In addition, scattered drilling shows the presence of #5 coal 4' to 5' in thickness or approximately 78,600,000 tons in place, of which about 47,000,000 tons should be recoverable.

The coal north in Block #4 is owned by the U. S. Steel Corporation, but the other three sides are open as far as I can tell except for the scattered Burr Oak holdings.

Blocks #1 and #4, as stated above, are owned by the Franklin County Coal Corporation. Ira Westbrook, attorney, is a Trustee and is handling the affairs.

Black Star, which has Block #2, is owned by Roy Carter, who is President of the Company.

Burr Oak is handled by Louis Francour of Francour & Company, investment bankers.

Newton Luarco with the Carter Harrison interests, represents the bond holders of the Franklin County Coal Corporation, and I believe, is Secretary of Burr Oak.

Olin Mathison is a minority stock holder of Burr Oak, that acquired this as a liquidated debt some years ago.

There is some oil production on the Burr Oak and Franklin County properties, but as far as the coal is concerned, the three organizations have agreed to sell as a package. McCulloch has been offerred a commission for handling this, but we are at liberty to talk with the principals at any time. Bill has made no concerted effort to sell this, but has discussed it all over the coal field. He has offerred it to U. S. Steel and as far as I can tell, his price was $50.00 per acre. He would not give me a firm price, but insinuated that $50.00 would take it. He does not know whether or not all cash would be required. This would take $446,000 at the $50.00 price. He tells

me that certain operators have scoffed at this figure. Of course, the acreage to be purchased from individuals is not figured in the price of $446,000.

A map showing the area is attached.

KOLBE DEPOSITION EXHIBIT Y

November 7, 1955

Mr. R. J. Hepburn:

I think it best to put down in writing some of our problems in order that we can discuss them intelligently at a later date.

Years ago we had a fairly good Engineering Department. We handled the acquisition of all reserves, the prospect drilling, mapping, building of railroads, bridges, haulage roads, projection of the pits, monthly surveys and reports, planned all drainage work, saw to it that all obstacles to our stripping were removed, kept up not only the topographic but the maps of the various plant areas showing all changes in railroad tracks, pipe lines, power lines, hoppers, etc., analyzed the efficiency of the shovels as well as preparing a shovel report, did the same with the drills, and in general formed a base on which the mines operated. This deteriorated throughout the years from lack of direction and inadequate help.

We now have only two engineers in the field. In Fulton County we have Riley who can be used to good advantage if handled properly. He is capable and willing and I think is learning that the Superintendent is boss. Inman when he arrives will help a great deal. The set-up is not too good regardless of who is there and the engineer continues operating entirely out of the Canton Office.

Cuba is an easy problem in that the present pit will be extended for the life of the mine. We have no new fields to enter as the remaining coal is in a solid block. We will acquire no more property from individuals and once our mapping is completed little engineering work will be required unless major changes are made. It would be wasteful to have an engineer at the mine constantly as long as the mine is under its present set-up.

Buckheart has been in a state of flux ever since it started. It has been a high production mine since 1938. It is a difficult field in that the coal is and has been in many

divided areas. There is much more property to be acquired and the plans for mining in the remaining acreage must be completed and this is a major job. A good engineer really should have his headquarters at the mine and he should be much more than a transitman. He can make himself the most valuable man at the mine next to the Superintendent if he will. There are no facilities for an engineering office there and it should be near the Superintendent. As long as an engineer is in the Canton Office rather than at the mine he will not be used nearly as much as though he was right underfoot.

Mine No. 19 requires little engineering work outside the mine other than transit work and 40 or 50 acres of topography that must be done when our crop line drilling is a little more complete. Donaldson is an engineer himself and does more engineering work than he wants anyone to know about.

Mine No. 25 requires little work at the moment.

At Mine No. 11 we have one man who has some value but is an architect rather than an engineer and as far as I can determine has no particular ambition or desire for responsibility. This is a difficult position to fill and should be held by a man with considerable force. A confident engineer could make himself more valuable here than any mine I know but with our present help we are limited to roughly measuring yardage, shooting in blast holes, making monthly surveys and a few miscellaneous odd constructions jobs and running errands. Holloway is fairly good on structural work and has been a help there.

Our Office Engineer can do beautiful drafting work for reports, etc., but little or no experience in stripping or with any of the problems at the mines, and is not too much inclined to get along well with others. The monthly reports and annual reserve reports are prepared here and there is considerable room for improvement in this line. However, our engineers in the field have been lax in the past in submitting full information with their surveys but I believe this will be corrected.

As to myself, because of lack of help I am neglecting more work than I am doing and have for some time. Traveling alone taken up far too much time. In the past twenty-one months I have driven 77,000 miles at an average of 50 miles per hours. This figures out to 64 days of 24 hours each, or over 10% of the time. This does not include a substantial amount of plane and train travel. This is caused principally by having too many irons in the fire with insufficient help and it means that everything necessary cannot be done. Frankly I would be lost without too much work but the way it is handled at present is not very fair to the Company.

We had until about two years ago a Land Man in Fulton County who kept in touch with everything going on. He was never replaced. I think that Inman can be broken in on this to a considerable extent but, of course, he cannot spend full time at it. We need a local man who either knows or can know everyone and every piece of property in the coal bearing area. Most of our competitors keep someone in each locality where property is to be acquired, either on a salary or a commission basis. On one job in Kentucky Sinclair had such a man for a scout, then when they wanted to acquire the property selected, they brought in 21 oil scouts from Oklahoma and took up the field in two or three days. This was at a time when they had competition in the area.

We have during the years examined something over 200 coal fields. Of those we have taken up, either wholly or partially, only seven. Some of the best were dropped without going into. Some of them taken perhaps not too wisely. The constant search for and investigation of new properties should go on but someone should be broken in to help with this. While there is a report in the files on everything we have ever looked at, it is not necessarily complete as it is not practical to get complete information in a day. It takes someone with the ability to go up with a topographic map, note the outcrops and prepare a rough estimate, as well as dealing with the landowners or promoters. A great deal of the information on topography, coal seams, operations, the various

promoters, prices of land, etc., can hardly be put down on paper. Someone else should be trained to know what he is looking for when he goes into a prospective coal field.

Practically all of our competitors have a far better organization for prospecting than we. Ayrshire, for instance, has at least six drills generally in operation and all under the supervision of a Drilling Superintendent. They also have an engineer following up on the drills at all times so that the surveys of locations, elevations, etc., are always up-to-date. I have seen Sinclair prospect a field with eleven drills while probably that many more were in other fields. While these eleven drills were working the Drilling Superintendent was pushing them and there were several engineering parties in the field. They were able to have their complete estimates in a very short time. Incidentally, this was in a field we turned down for certain reasons but has made a profitable operation for them.

I would like to discuss the entire problem at length with you, either here at the office or some place where we can have plenty of time to go over it thoroughly as I am afraid we are not building up properly the basis on which our future lies.

T. H. LATIMER

* * *

	Plant	Type of Reactor	Installed Capacity (thous. kw)	Net Generation (million kwhr)	Kind of Fuel Used
12	Haddam #1	Pressurized water	600.0	524.1*	Enriched uranium
	*Consists mainly of test generation during late 1967. Plant was placed in commercial operation in December, 1968.				
12a	Rowe	Pressurized water	185.0	1,272.8	Enriched uranium
12b	Indian Point	Pressurized water	275.0	1,622.0*	Enriched uranium
	*Includes kwh generated by oil. (Plant is designed for production of electric energy by both nuclear and conventional fuels.) Used 228,307.66 grams of uranium at 27.767¢ per million Btu and 863,788 bbl of oil at 149,112 Btu per gal., $2.04 per bbl and 32.7¢ per million Btu "as burned."				
12c	Shippingport	Pressurized water	100.0	455.6	Natural and enriched uranium
12d	Saxton Nuclear	na	10.0	6.9*	na
	*Generation by Saxton (non-nuclear) plant from steam supplied from small nuclear reactor adjacent to plant and owned by Saxton Nuclear Experimental Corp.				
12e	Peach Bottom #1	High temp., helium cooled, graphite mod.	46.0	144.2	Uranium
	Plant used 12,394 grams of uranium at 29.7 cents per million Btu.				
12f	Dresden	Boiling water	208.7	807.0	Enriched uranium
12g	Big Rock	Boiling water, high power density	75.0	502.0	Uranium dioxide
	Plant used 67,157 grams of U235.

KURTZ DEPOSITION EXHIBIT 9

BITUMINOUS COAL FACTS 1966

• • • •

The transportation revolution is not limited to the carriers of bulk coal. Another comparatively new development is the mine-mouth generating station that uses a coal-by-wire technique. A single huge generating station, built almost atop a coal mine, can serve several utility systems through extra-high-voltage transmission line interconnections.

Mine-mouth generating stations are becoming more numerous in such states as Pennsylvania, West Virginia and Illinois where the reserves of coal are available and consumer demands are rapidly increasing. • • •

Figures are for resources in the ground, about half of which may be considered recoverable. Includes beds of bituminous coal and anthracite 14 in. or more thick and beds of subbituminous coal and lignite 2½ ft. or more thick.[a]

[a] By Paul Averitt, U.S. Geological Survey.

[b] Estimates from published reports of the U.S. Geological Survey and individual State Surveys reduced by production and losses in mining from date of estimate to Jan. 1, 1967. Losses assumed to be equal to production.

[c] Estimates by G. H. Ashley (Pennsylvania), H. C. Beekman (Washington), M. L. Corbett (Montana), J. Hazel and C. A. Brant (Ohio and North Carolina), W. C. Culbertson (Arkansas), N. A. Eby (Pennsylvania), D. R. Hasey (Arkansas), E. R. Landis (Colorado and Iowa), E. T. Luther (Tennessee), R. S. Vasser (Oregon), F. C. Peterson (Kaiparowits Plateau, Utah), J. A. Simon (Illinois), J. V. A. Trumbull (Oklahoma), C. E. Weir (Indiana), and Paul Averitt for the remaining States.

[d] Small resources of lignite included under subbituminous coal.

[e] Small resources of anthracite on the Dering River bed believed to be too badly crushed and faulted to be economically recoverable.

[a] Small resources of lignite in beds generally less than 28 in. thick.

[b] Arizona, California, Idaho, Nebraska, and Nevada. Bituminous coal in Black Mesa bed, Arizona included under subbituminous coal.

[c] Arizona, California, Idaho.

[d] California, Idaho, Louisiana and Nevada.

LATIMER DEPOSITION EXHIBIT 25

September 25th
1964

Mr. R. J. Hepburn

GRUNDY COUNTY, ILLINOIS

North of Morris there are approximately 3200 acres north of Interstate 80 and west of Illinois 47, which is indicated as No. 2 coal under the 75′ overburden line. West of this the coal continues for one-half mile to a mile before the 100′ overburden line is reached. I can find no ownership by any coal companies. This is very good farm land, but probably not quite as high value as that mentioned northwest of Ottawa.

In and around the town itself Sentry Royalty Company owns a considerable acreage consisting mostly of old strip pits formerly operated by the McElvains. This was acquired when Northern Illinois, Broken Arrow, Homestead, Sunlight and Wilmington Coal Mining merged with Sentry.

South of Morris the Sentry holdings are shown on the plat book and I can find nothing that they acquired since the merger. We have wondered why the old Northern Illinois pit stopped in Sections 17 and 20-33-7, and did not mine the coal between that line and the Mason River. I find that Northern Illinois showed several pieces in here when they were operating, but the tracts were all owned by people who also owned land in the old Northern Illinois area. All but one of these pieces were sold off and Sentry has only 40 acres in the SW¼ of Section 18. This may indicate that the coal is either not there or not mineable.

East of Route 47 and west of the Mason River, there are approximately 1000 acres under 75′ indicated and this can be increased by about 2460 acres by going to the 100′ cover line. All of this is a moderate grade to good farm ground and over 50 owners are involved. There is another 640 acres north of and adjoining this

which is under 75', but it contains many small homes, a new subdivision and a cemetery and I don't think there would be much chance to get it. Adjoining this on the east side of the Mason River there are about 1500 acres of pretty good farms probably under 75' of overburden.

South of Morris, west of Route 47 in the only mineable coal shown under 75' is the Material Service gravel pit on which you already have a report from Bob Inman. South of this there is less than 1000 acres between 75' and 100' and I don't think you would want to try to mine it. Most of it is very poor grade, but it too is probably a future gravel pit.

There is no ownership by any coal companies that I can find other than that shown on the plat book.

LATIMER DEPOSITION EXHIBIT 38

July 19th
1966

Mr. R. H. Inman

As I understand it we are only planning to take up three of the options to lease we presently have. One of these, Tillery, must be renegotiated as his present contract covers 160 acres and we only want 40 of it. These contracts are as follows.

Tillery expires August 15th—160 acres—$5440.00 payment *

Allen expires September 1st—40 acres—$1360.00 payment

Pollack expires September 24th—240 acres—$8160.00 payment.

* Renegotiate or drop

Exercising of any of these will make us liable to take up the Mason contract of $42,350.00 on November 8th. This contains 182,000 tons.

As I have reported to you we are having very little success in taking up additional leases in the field. We are in an area of better and independent farmers who are tired of having optioned and will not take royalty contracts. Some of them also want an amount equal to a years taxes for permission to drill and will only grant short time options to purchase and higher prices, perhaps $500.00 or more with the right to take other property in exchange instead of cash. They are difficult to deal with, but we might drop the Tillery contract and let him know we will try to make a deal on 40 acres later and this would give us until a week or so before September 1st to try to negotiate new contracts and drill them all out. Otherwise, I think we will have to drop the field.

1961

Mr. R. J. Hepburn

HUNTSVILLE FIELD—SCHUYLER COUNTY

Rusty and I have covered this area pretty well, and as you have been informed, several of the land owners would like to option. While it is impossible to make an estimate of the field without drilling, judging from the many strip pits and outcrops, we should have options in each of the following sections:

3, 4, 5, 6, 7, 8, 9, 10, 11,
14, 15, 16, 21, 22, 23, 28.

I do not mean that we should option the entire 10,240 acres at this time, but as people from each section come to us it would be well to have an option in each section. Should 60% of the area be coal bearing and under 80' of overburden, this would give a potential of 18,340,000 tons of coal.

North and west of Huntsville township there is also an area of perhaps 5,000 acres extending over to a point very close to the Burlington Railroad.

From the center of the Huntsville township field it is 7 miles air line to the Burlington on the northwest and 9 miles to the Wabash to the southwest.

GOVERNMENT EXHIBIT Mag. Dep.

GENERAL DYNAMICS
CORPORATION

445 PARK AVENUE, NEW YORK 22, N.Y.

To the Share Owners: November 24, 1959

Your proxy is being requested to vote in favor of the merger of Material Service Corporation of Chicago, Illinois, a leading Midwest producer and supplier of building materials, concrete, coal and limestone, into General Dynamics Corporation as the Corporation's Material Service Division.

The Directors of Dynamics believe that the merger of MSC into Dynamics is not only to the immediate and long-term financial advantage of the share owners, but serves well a basic corporate objective of Dynamics, namely, to generate commercial earnings that will balance earnings from defense projects.

Position of Dynamics in Defense

Since the security of the nation is of paramount importance, the Directors of Dynamics are satisfied that large-scale defense activities must be a major and long term function of the American economy.

The Directors are equally satisfied that Dynamics will continue to contribute in large and important measure to the aircraft, missile, space, electronic and nuclear programs of this nation.

Position of Dynamics in Commerce

Despite the long term needs of the nation's various defense programs, considerations of growth and stability dictate that a conservative corporate management actively seek diversification in commercial, non-defense business.

The Directors expect to achieve this diversification through development of commercial products stemming from present programs, such as: the Corporation's Convair 880/600 jet transports; Canadair's commercial turbo-prop CL-44 and CL-540 aircraft; General Atomic's nuclear research, maritime and power reactors; Liquid Carbonic's industrial gases; and Stromberg-Carlson's telephone and high fidelity sound equipment; and from the acquisition of companies which, because of technical capability, quality products and managerial competence, have demonstrated substantial earning power in industries basic to the nation's commercial future. The Directors are of the opinion that MSC is such a company.

Advantages of Merger to Dynamics

Members of the Board of Directors and the Board of Management, after careful study and inspection of the organization, management techniques, properties, equipment and skills of MSC, believe that the earnings record of MSC is due to management competence, and to a high degree of mechanization of mines, quarries, plants and transportation equipment, resulting in competitively lower-cost operations.

Dynamics would acquire an enterprise with an experienced management team of proven capability accustomed to operating under vigorous competitive conditions and with the most modern of extraction and transportation equipment, supplying basic materials to the steel, utility and construction industries.

The acquisition of a supplier of materials to the steel, utility and construction industries would give Dynamics basic participation in the expansion of the nation's physical plant and facilities to meet the demands of the growing economy and the accelerating population growth.

* * *

3. Freeman Coal Mining Corporation:

Freeman Coal Mining Corporation, an Illinois corporation and a wholly-owned subsidiary of MSC, operates directly or through a subsidiary 4 coal mines, namely, Crown Mine, Orient #3 Mine, Freeman Mine #4 and Orient #2 Mine, and has a fifth mine, Orient #5 Mine, under construction. All of such mines are located in Illinois. Each of the mines has an adjacent preparation plant. Effective as of the merger, all the coal reserves in and adjacent to each mine which are owned or controlled, directly or indirectly, by members of the families of Henry, Irving, Herman and Edward A. Crown ("Crown families") will be leased to Freeman on a royalty basis.

According to "Coal Age" for February, 1959, Freeman, with the production of these mines, ranked ninth among coal companies in the United States for tonnage produced in 1958. The production of these 4 mines in 1958 aggregated 6,872,541 tons, as follows—Crown Mine—1,578,623 tons; Orient #3 Mine—3,032,634 tons; Freeman Mine #4—1,071,377 tons; and Orient #2 Mine—1,189,907 tons.

The Crown Mine is located about 27 miles south of Springfield, Illinois, in Montgomery County. The coal reserves in and adjacent to this mine include a block of approximately 130 million tons of Number 6 seam coal, 6 to 8 feet in height and of relatively uniform quality. The sulphur content is approximately 3½% and the BTU value is approximately 10,700 per pound. The estimated life of the deposit is approximately 70 years based on the rate of production in 1958. The coal produced by the Crown Mine is used principally for consumption by utilities. The most important contract for the sale of the Crown Mine's production is with one public utility. The lessor of the coal reserves is comprised of several trusts, the principal beneficiaries of which are members of the Crown families. The surface lands around the mine are owned by Freeman.

The Orient #3 Mine is located in southern Illinois. The coal reserves in and adjacent to this mine include a block of approximately 220 million tons of low sulphur, Number 6 seam coal, 7 to 12 feet in height. The sulphur content is about 1% and the BTU value is approximately 12,200 per pound. The estimated life of the deposit is approximately 65 years based on the rate of production in 1958. The lessor of the coal reserves is a wholly-owned subsidiary of The Chicago, Wilmington and Franklin Coal Company, a Massachusetts corporation, which is controlled by members of the Crown families.

The Freeman Mine #4 is located in southern Illinois. The coal reserves in and adjacent to this mine include a block of approximately 30 million tons of Number 6 seam coal, 6 to 7 feet in height. The sulphur content is about 2½% and the BTU value is approximately 12,300 per pound. The estimated life of the deposit is approximately 20 years based on the rate of production in 1958. The lessor of the largest of the three leases covering the reserves of this mine is comprised of several trusts, the principal beneficiaries of which are members of the Crown families.

The Orient #2 Mine is located in southern Illinois. The coal lands are leased and cover a block of approximately 2,800,000 tons of Number 6 seam coal, approximately 8 feet in height. The sulphur content is about 1¾% and the BTU value is approximately 12,150 per pound. The lessor of the coal lease is a wholly-owned subsidiary of The Chicago, Wilmington and Franklin Coal Company. The surface lands around the mine are owned by Orient Number Two Coal Company, a wholly-owned subsidiary of Freeman. It is contemplated that the operation of this mine will be continued for approximately 18 months at which time it is anticipated Orient #5 Mine will be in operation.

The Orient #5 Mine is located in southern Illinois. This mine is under construction and will be in operation in approximately 18 months. The coal reserves in and adjacent to this mine include a block of approximately 32 million tons of Number 6 seam coal, 8 to 10 feet in height. The sulphur content is about 1¾% and the BTU value is approximately 12,150 per pound. The planned rate of production is 1,600,000 tons per year. If this rate is maintained, the life of the deposit is estimated to be approximately 20 years. The surface lands around the mine are owned by Freeman. There are 2 coal leases. The lessor under one of the leases is a wholly-owned subsidiary of The Chicago, Wilmington and Franklin Coal Company. The lessor of the other lease is comprised of several trusts, the principal beneficiaries of which are members of the Crown families.

The royalty rates provided for in the leases covering these 5 mines range from 7.5¢ to 13.1¢ per ton; only a minor portion of the tonnage is subject to a royalty in excess of 10¢ per ton. The

* * *

(c) As of October 31, 1959, MSC owned 231,503 shares of Common Stock (approximately 34% of the issued and outstanding shares of such stock) of The United Electric Coal Companies, which shares will be acquired by Dynamics upon the merger.

(d) Forty-one stockholders of MSC, consisting of Henry, Herman, Irving and Edward A. Crown, of members of their families, of trusts of which certain members of their families are the beneficiaries, and of the Arie and Ida Crown Memorial, a charitable foundation of which Henry, Irving and Edward A. Crown are directors, own of record 74,323 shares of Common Stock of MSC, or over 97% of the 76,543 shares of such stock outstanding at October 31, 1959.

REMUNERATION OF CERTAIN DIRECTORS AND OFFICERS OF GENERAL DYNAMICS CORPORATION AND OF MATERIAL SERVICE CORPORATION

General Dynamics Corporation

The following information with respect to the remuneration of Directors and officers of Dynamics for the year ended December 31, 1958 and with respect to the estimated annual benefits upon retirement of the persons named appeared in the Proxy Statement of Dynamics dated March 27, 1959, which was mailed to stockholders of Dynamics in connection with the Annual Meeting of Share Owners held on April 23, 1959:

The following tabulation sets forth the direct remuneration of each Director, and of each of the three highest paid officers, of Dynamics whose direct aggregate remuneration from Dynamics and its subsidiaries exceeded $30,000 in 1958, and of all Directors and officers as a group, and the estimated annual benefits upon retirement of the persons named:

Name of individual or identity of group	Capacities in which remuneration was received	Aggregate remuneration for the fiscal year ended 12/31/58(b)	Estimated net remuneration after current income taxes (c)	Estimated annual benefits under applicable retirement plan(d)
Frank Pace, Jr.	Director and President of the Corporation; Chairman of the Board and Director, Canadair Limited	$ 144,167	$89,386	$66,000
Earl D. Johnson	Director and Executive Vice President of the Corporation; Vice Chairman of the Board and Director, Canadair Limited	126,750	55,497	35,450
Joseph T. McNarney (a)	Director and Senior Vice President of the Corporation; Consultant to the Corporation	80,282(e)	42,957	(e)
J. V. Naish (a)	Senior Vice President of the Corporation; President, Convair Division	105,750	50,348	31,768
All Directors and officers of the Corporation as a group (including the above named, but excluding assistant officers)		1,448,234	not applicable	not applicable

(a) Mr. McNarney retired as a Senior Vice President of the Corporation and as President of the Convair Division of the Corporation, effective March 31, 1958, and continued as a consultant. On April 25, 1958 Mr. Naish who had previously been Executive Vice President of the Convair Division, was elected a Senior Vice President of the Corporation and President of the Convair Division.

(b) Includes incentive compensation payments made in 1958 with respect to 1957 operations as follows: Mr. Johnson, $40,000; Mr. McNarney, $35,000; Mr. Naish, $35,000; all Directors and officers of the Corporation as a group (including the foregoing, but excluding assistant officers), $315,500. The Incentive Compensation Plans of the Corporation and Canadair Limited provide for the distribution of a maximum of 5% of the profits before taxes with respect to any given year after deducting therefrom an amount which after taxes is equal to a 6% return on capital employed, as defined in said Plans; persons eligible to participate are those employees of the Corporation or of Canadair Limited, respectively, who are mainly responsible for management operations.

(c) After Federal income taxes, assuming no other income during 1958, each individual being married, having two dependent children and filing a joint return, and 1958 tax rates.

(d) These estimates computed as of December 31, 1958 assume retirement at normal retirement age and include the amount of benefits provided by the individual's own contributions as well as those made by the Corporation.

(e) Mr. McNarney does not participate in the Retirement Plan of the Corporation, but, in addition to a consulting agreement, has a contingent deferred remuneration agreement under which he qualified on April 1, 1958 for additional compensation, provided that he complies with the conditions of his contract of employment. The amount of $3,779 of such compensation was accumulated during 1958 through the date of Mr. McNarney's retirement, after which date no further accumulations were or will be made under said agreement. As of December 31, 1958 the unpaid balance of such compensation amounted to $86,644, payable over a period of years at the rate of $453 per month; upon death, any unpaid balance is payable to his beneficiary.

MAGUIRE DEPOSITION
EXHIBIT 35

7. United Electric Coal Companies - Purchase of Stock

The Chairman referred to the discussions at the last Board meeting regarding the purchase of additional stock of United Electric Coal Companies. He reported that, as authorized by the Board, the Corporation had acquired 48,400 shares of UEC from Material Service Employees Profit Sharing Trust at $50.50 a share, which represented the cost to the Trust of acquiring and carrying the stock.

The Chairman then stated that management had considered further the advisability of acquiring the remaining minority interest in UEC and, for various reasons, had concluded that the Corporation should proceed with a plan of acquisition at this time. He asked Mr. Sargent to present the management's views.

Mr. Sargent reviewed for the Directors the charts containing financial data on UEC which had been presented at the

last Board meeting, and noted the amounts that would be required on various assumptions to acquire the remainder of the UEC stock. He stated that the management still felt that the most direct method of acquiring the balance of the UEC stock was through a combination of a tender offer for an additional 170,000 UEC shares, which would bring the Corporation's holdings to slightly more than 90%, and a "short form" merger, available under Delaware law to a 90% holder, under which any remaining minority would be paid the fair value of their shares. He stated that under the "short form" merger provisions, UEC could be merged directly into the Corporation or into a new Delaware subsidiary to which the Corporation would first transfer its UEC shares, in either case by action of the Board of the parent. He stated that if the tender offer were a success the merger would be effected as promptly as possible and steps would be taken to provide management for UEC and to combine UEC and Freeman marketing and other administrative functions and staffs where efficiencies and cost reductions could be achieved. He stated, however, that in the first instance the UEC coal properties and contracts would be held separately from those of Freeman, most probably in the new Delaware subsidiary.

Mr. Sargent then reviewed the various considerations in support of the management view that the minority interest in UEC should be acquired and that Freeman and UEC should be combined as soon as possible, including a review of UEC's limited coal reserves and the resulting problems UEC had encountered in obtaining and keeping long term contracts, the ability of Freeman to provide a back-up of reserves over the long term and finally

the requirement for a new chief executive officer and other key personnel on which action should be taken promptly. He also reported that the New York Stock Exchange indicated its intention to delist UEC within the next few weeks. He stated that, in general, the combination of the two operations made good business and operating sense and would insure the ability of the enterprise to compete more effectively in its market. He stated further that, under all the circumstances, the Corporation's legal staff was not aware of any legal reason why the Corporation should not proceed with the plan.

The Directors discussed the matter of a tender offer price, in the course of which it was pointed out that it is normal in tenders of this kind to offer a premium over market of between 15% and 20%. Mr. Sargent then reviewed the market action of UEC stock over the last few months in which he noted that in July, when the possibility of a tender offer was first discussed, UEC was selling at 39-1/2, and that on August 3, the day before the meeting of the Board at which the tender offer was to be considered, the price of UEC had risen to 49. He stated that subsequent to the August meeting the price of the stock dropped sharply. The current market is about 42. Mr. Sargent then stated that, in his opinion, the Corporation should not, under present conditions, pay more than $50 a share on the tender offer, which provided a sufficient premium over the market. The consensus of the Directors was that $50 a share would be a proper offering price at this time.

Mr. Sargent answered questions by various Directors about the Corporation's cash position, the status of bank loans,

the effective rate of interest being paid, compensating balances, and all other factors relating to the Corporation's ability to finance the tender offer and the payout to the minority stockholders on the "short form" merger. The remaining Directors were polled and, in view of the business considerations detailed by management, all concurred in the recommendation to proceed with the tender offer.

Mr. Sargent stated that, as he had noted earlier, on a Delaware "short form" merger, the minority are entitled to be paid the fair value of their shares, exclusive of any element of value arising from the merger. In the first instance the Corporation or the Board of the new subsidiary would set the price, and any UEC share holder objecting to the price could seek appraisal under Delaware law. He stated that management did not have a final recommendation on the price to be offered on the merger, but that he was certain that it would not exceed $50 a share and might be less.

Mr. Sargent stated that it was proposed that Chase Manhattan Bank be designated as Tender Agent, that Georgeson & Co. be retained to assist on the tender offer and that a fee of 50 cents a share be paid to soliciting brokers. He then submitted to the meeting the proposed Invitation for Tender and Form of Tender and Assignment. He stated that these documents were substantially as submitted and reviewed at the August Board meeting, except that UEC earnings data for the first nine months of the year had been included. He stated that the documents had also been cleared with the New York Stock Exchange. The Chairman

directed that copies of the proposed Invitation for Tender and Form of Tender and Assignment be filed with the records of the meeting.

Mr. Sargent stated that, in addition to authorizing the tender offer and related action, it would be appropriate at this time for the Board to authorize the management, in its discretion, to organize a new Delaware subsidiary, to transfer the UEC stock to such subsidiary and to take such other action as would be required to effect the "short form" merger on the basis proposed. He stated that it was expected that the definitive plan for the combination of UEC and Freeman would be developed in time to permit its consummation by the end of the year.

After further discussion, on motion duly made, seconded, and unanimously carried, it was

RESOLVED, that the Corporation make an offer (hereinafter in these resolutions called the Tender Offer) to purchase shares of Common Stock of The United Electric Coal Companies (hereinafter in these resolutions called UEC) by inviting tenders for such shares at a price of $50 per share in the manner and on the other terms set forth in the instruments hereinafter in these resolutions approved; and further

RESOLVED, that the form, terms and provisions of the proposed Invitation for Tenders and the proposed Form of Tender and Assignment to be used in connection with the Tender Offer, copies of which have been submitted to this meeting, be, and hereby are, approved, with such changes therein as the President or the Vice President-Finance of the Corporation and Counsel for the Corporation may deem necessary or advisable and approve; and further

RESOLVED, that The Chase Manhattan Bank, N.A., be, and hereby is, designated as Tender Agent of

the Corporation for the purposes of the Tender Offer; and further

RESOLVED, that the President, the Vice President-Finance or the Secretary of the Corporation be, and each of them hereby is, authorized to

(a) engage The Chase Manhattan Bank, N.A., as Tender Agent of the Corporation in connection with the Tender Offer;

(b) extend the termination date of the Tender Offer to such date (not later than November 21, 1966) as they or any of them shall determine;

(c) pay commissions or fees to brokers responsible for soliciting tenders of shares of Common Stock of UEC;

(d) retain solicitors to assist in connection with the Tender Offer;

(e) deliver to the Tender Agent such instructions as they or any of them shall deem necessary or proper in connection with the Tender Offer (which instructions shall designate the persons authorized to act for and on behalf of the Corporation in connection therewith); and

(f) take all such other action as they or any of them shall deem necessary, proper or advisable in connection with the Tender Offer and the implementation of these resolutions or any of them; and further

RESOLVED, that the President, the Vice President-Finance, or the Secretary of the Corporation be, and each of them hereby is, authorized to take all such action, in the name and on behalf of the Corporation, as shall be necessary or proper to

(a) at such time as the Corporation shall own not less than 90% of the outstanding stock of UEC, cause UEC to be merged into the Corporation and, in connection therewith, set the terms and conditions of the merger (provided that the consideration to be paid for shares of UEC shall not exceed $50 a share) and execute and file a certificate of ownership and merger, all in accordance with Section 253 of the Delaware General Corporation Law;

(b) form a new corporation under the laws of the State of Delaware (hereinafter called New Corporation);

(c) execute, in the name and on behalf of the Corporation, a subscription agreement with New Corporation providing for the purchase by the Corporation of all the authorized capital stock of New Corporation for not more than $1000;

(d) as an alternative to the actions authorized pursuant to (a) above, transfer to New Corporation, as a capital contribution, all the shares of Common Stock of UEC owned by the Corporation (including, but not limited to, the shares of Common Stock of UEC to be purchased by the Corporation pursuant to the Tender Offer); and

(e) at such time as New Corporation shall own not less than 90% of the outstanding stock of UEC, cause UEC to be merged with and into New Corporation in accordance with Section 253 of the Delaware General Corporation Law upon such terms and conditions as said officers or any of them shall deem advisable, and in connection therewith to cause the Corporation to advance to New Corporation such funds as may be necessary to enable New Corporation to effect the terms of said merger.

experimental installation. Evaluation of the economic feasibility and effectiveness of this system must be deferred until after shakedown runs are complete.

Electrostatic precipitators - Electrostatic precipitators are the most common gas cleaning devices used to remove particulates from the flue gases of large stationary combustion sources. Such devices are capable of collection efficiencies of at least 99.5 percent, and it is quite possible that even more efficient systems can be provided if necessary. Electrostatic precipitator systems are usually applied to large pulverized coal-fired power boilers. The cost of these systems has limited their use on smaller combustion sources.

Electrostatic precipitators are highly sensitive, and if not properly designed, small changes in the properties of the particles and the gas stream can significantly affect their collection efficiencies.[22] Allowance should be made for possible changes in fuels, in fuel composition, and in gas temperature when consideration is given to the use of electrostatic precipitators. It has been established that low-sulfur fuels adversely affect the particulate collection efficiency of electrostatic precipitators designed for high-sulfur fuels.[23]

Fabric Filters - Fabric filters are not commonly applied to stationary combustion sources. Factors which limit the use of these devices are uncertainty of performance and reliability, and availability of other effective gas cleaning devices.

MORRIS DEPOSITION EXHIBIT 3

December 17, 1959

Mr. J. M. Morris:

We have made another checkup or study on the amount of coal left in our Danville property. Producing as we are at this time, we estimate that our coal will run through the month of June. It is possible there will be some to take out after the miners' holiday, but it will depend on how the requirements of the light company are between now and then. If we come up to vacation time and it looks as if there is a small amount of coal left, we probably would be better off to work through the vacation period and complete it rather than go on vacation and then come back.

We have made a further study of the acreage just north of us on which we had hoped to pick up 250,000 to 300,000 tons of coal. In our previous drillings we had put some holes down for checking this possible amount of tonnage and evidently were unfortunate enough to have several of our drill holes go through some pillars. After plotting from an old map obtained of some underground workings and doing some additional drilling, we found that a considerable amount of what we thought could have been coal had previously been mined by underground methods. Taking this map, therefore, as being correct, and taking into consideration the gas line that crosses this property, there would be a small area of approximately eleven acres that could be mined without removing or moving the gas line, but to do this, box cut spoil would have to be thrown over the line and then leveled. This area, being of the nature it is, already congested with homes and businesses, would be very hard to mine without doing extensive reclamation and leveling. Taking for granted that the royalty we would have to pay for this coal would be offset by depreciation for an additional three months of operation, we theoretically should make 65¢ a ton on the one hundred thousand tons available. However, we would have to extend our power lines, drainage, a haulage road, and other incidentals, which could run easily $15,000 to $20,000, and we in operations feel that from a mining standpoint we should not consider mining this area and therefore have come to

the conclusion that the Danville mine will terminate as a strip mine the middle of the summer.

Another suggestion that we may have for Danville might be the purchase of the V-Day Coal Company, operated by Mr. Zamberletti. He has an underground operation across the hard road from our Mary Moore property which he has been mining as he desires during the winter months, producing No. 6 underground coal which underlies our Mary Moore property and the Peabody Estate property to our south, where we have removed the upper or No. 7 vein. This No. 6 vein underlies the No. 7 seam 30-35 ft. which we have not drilled out but which from some of our drill holes seems to have pretty fair cover, some shale and rock. Under our Mary Moore property there could be a million two hundred thousand tons in place and an additional eight hundred thousand tons in place under the Peabody Estate. Mr. Zamberletti has other coal leases, and south of him we know that U.S. Steel controls underground No. 6 coal. Mr. Zamberletti has been approached and I believe his property would be for sale. It might be well to take this up with Mr. Nugent. They can make an inspection for us and engineering-wise help us. It might be the thing to do to purchase this property to continue our Danville light contract. If we could get an estimate of what the underground cost might be, this coal could be trucked from the slope opening in our trucks to our plant to be crushed for loading on the C. & E.I. Otherwise it would have to be crushed in his plant and then trucked to the light company. If this could be put into operation, I feel a slope could be put on or near our property, which would shorten the overland road, maintenance and haul, and cut out the crossing of a highly traveled state route.

I would be glad to discuss this situation with you or Mr. Nugent at any time.

Mr. Frank Nugent, President
Freeman Coal Mining Company
Division of General Dynamics Corp.
300 West Washington
Chicago, Illinois

Dear Frank:

Here's something that may be worth looking in to. You recall our sales agreement with Ruby, Chandler-Jordan on the production of the Ruby Mine. This was a strip—went into operation in 1953 and mined out all of the #11 strip in the area in 1961.

They control the underground #9 in the same area approximately 1200 acres which would mine out about six million tons of raw coal. Coal appears to be from 100 to 150 feet deep, average 4.75 feet thick, slate roof and good average quality #9 coal comparable to that mined by West Kentucky Coal Company now at their East Diamond property. This field joins the East Diamond workings.

The tipple, washing plant, shop, store house and office buildings are still there and about 10,000 feet of railroad track. All of the above are in good condition and the original cost of the plant and buildings was approximately $500,000.00. For income tax purposes this was all charged out when the mine worked out the available acreage. So rather than re-open this tax case, the owners would sell to a prospective Lessee all of the above including land, for $10,000.00.

While the mine is local on the Illinois Central Railroad, the market for coal with the TVA at present is better for L&N origin coal. A connection could be built with the L&N requiring about 2′ miles of track, if you don't cross the IC. If permission could be secured to cross IC, there would not be over ½ mile of track necessary.

The present owners of the coal rights make the following offer: 20¢ per ton royalty on any coal sold at 3.25 per ton f.o.b. mine or loss; six percent of the increase in price on coal sold above 3.25; thus, with a 3.50 realization royalty would be 21½¢, with 4.00 realization, 24¢.

Advance royalty of $2,000.00 per month starting June 1, 1966, would be required; this to apply against earned royalty when mining commenced. Under the terms of their lease on this coal a slope must be started prior to May 1, 1966, to show good faith that coal is actually going to be produced and of course, the advanced royalty starts one month later.

Of course, for underground coal this royalty is rather high. Whether or not this is subject to negotiation, I don't know.

The six million ton reserves is not large, but with everything there, except underground equipment, necessary amortization might be such that over a 10 year period would justify operation.

Also, I have another coal field in mind which I think we can acquire and after we are through here, equipment that is movable could be put into production at the other spot.

It occurred to me that this might offer an opportunity to gain a foothold in the West Kentucky Field and while it is not exactly what we would want, still, it has some possibilities.

George Chandler, 400 Country Club Lane, Madisonville, telephone 821-3188, is the man to contact and Abe Moore, attorney, MOORE, MORROW & FRYMIRE, telephone 821-6165, handles their legal affairs.

If this appears interesting you can contact either one of the above and arrange for some of your people to investigate it further.

I will be leaving here tomorrow and should arrive at St. Pete sometime Thursday. My telephone number there is area code 813, 898-8868.

Best regards.

CHICAGO, ILLINOIS 60601

March 14, 1966

Mr. Frank Nugent
Boca Raton Hotel & Club
Boca Raton, Florida

Dear Frank:

I will see you next week but in the meantime wanted to bring you up to date on the No. 9 seam underground coal near Clay, Kentucky, about which I have given you some information.

Joe Davis, who owns this, is now in a frame of mind to discuss turning it over to some company like Freeman for a future mine on the property. In the meantime two oil companies have entered the scene and are making a determined effort to get control of the reserves. He realizes, however, that this is a long-range proposition and probably will not mean a coal mine in the foreseeable future.

He also is still discussing with both Georgia and Alabama Power a long-term contract but has not as yet been able to get the kind of freight rate on a volume basis that appears necessary.

The TVA has a bid opening on March 29 and he may put in a price on this. He is talking in terms of $3.60 f.o.b. mine for raw No. 9 mine run, on which I am sure he can safely guarantee 11,900. This would be somewhat near recent award made to Bell & Zoller and might result in a contract. If he did get a contract, I think he would still be willing to discuss leasing the coal rights to someone else to operate.

I told him we were somewhat interested but it would take time to investigate and we would not commit ourselves until a thorough investigation and discussion could be had.

I will talk to you more about it when I see you.

Yours very truly,

Johnnie

GOVERNMENT EXHIBIT
Mor. Dep.
14

Mr. Frank Bogust, President
Freeman Coal Mining Corporation
A Division of General Dynamics Corporation
300 West Washington Street
Chicago, Illinois 60606

Dear Frank:

The attached statement shows the strip coal reserves at our various properties at the end of our fiscal year July 31, 1959 and as of April 30, 1965.

You will note approximately 10,000,000 tons more as of now, and during that period we produced at all mines 27,504,006 tons. This indicates that during the past six years we have acquired a total of approximately 37,000,000 tons assignable to strip operations.

The reserves shown for Cuba Mine ... 2,038,370 tons ... includes the present pit of about 500,000 tons which will be mined out the end of this year. The balance of approximately 1,500,000 tons is in the No. 6 field near the Cuba tipple. We do not plan on going into this area until after mining out that we hope to acquire from Truax in their West Cuba field, which we estimate will keep us operating for some eight or ten years.

Assigned to the Bushkeart property is the following:

Present Bushkeart area.	12,596,860 tons
South Bushkeart	11,256,275 "
North Canton field	17,518,958 "
	41,372,093 tons

If we complete our trade with Truax-Traer, because of the difference in overburden depth and thickness of coal seam, we will give up nearly 2,000,000 tons more in the North Canton area than we get back from them in the West Cuba field. Our reserves picture would then change by reduction in the 41,000,000 tons at Bushkeart and gain at Cuba, so our Bushkeart reserves will then total approximately 39,000,000 tons and our Cuba reserves approximately 8,000,000 tons. At an estimated 2,500,000 tons per year production at Bushkeart, we then would have about fourteen years life there and, as indicated above, from eight to ten years at Cuba.

You will note we have been unable to add any strip reserves of any consequence at Fidelity. We show 25,000,000 + tons April 30, 1965 against 28,000,000 tons July 31, 1959. Fidelity production should average about 2,000,000 tons per year and the present strip area on this basis would last about twelve years.

At Banner we mined during this period about 3,000,000 tons and show 8,006,781 tons now against 5,700,000 in 1959, so we have added there roughly 6,000,000 tons in the last six years. We think Harry Kitaljerg has around 1,500,000 tons which we should eventually get. Banner's production of approximately 700,000 tons annually, if we get Harry Kitaljerg's property, would give us a life there of about thirteen years.

I thought these figures would be of interest to you.

Yours very truly,

JHH:BF

GOVERNMENT EXHIBIT
Mor. Dep.
31

January 24, 1961

Mr. J. M. Morris:

With reference to your memorandum of January 24 concerning the Industry-McDonough No. 2 coal field, we had as of July 31, 1960, under our control approximately 4700 acres, of which 3300 acres contained coal amounting to approximately 12 million tons. This area is shown in orange and is covered by purchase contract, and that shown in yellow is now owned by the Company. We are showing where we think this No. 2 coal may lie within the blue outlines of the accompanying map. You will notice that this covers quite a distance in area of some fifteen or twenty miles from our present field. This is due, of course, to the estimated depth of the coal that we figure without drilling might be stripped. Our estimate, of course, is based on the contours from the Geological Department of the State, and in checking our drilling on the property we own with the contours in that location, they check fairly close. We therefore assume that these contours would be fairly close in these other areas, but it would not be our final opinion that this depth is accurate until we could be in a position to option some of this land and drill it out.

At this time we are having in mind a large area which might constitute 40 to 50 million tons of coal. If we have in mind a field of this type we must realize that we must have at least 20 thousand coal acres, which might consist of 30 to 35 thousand land acres. We must remember that for a mine of this type we would have to have several pits and no doubt several pieces of stripping equipment to maintain the production that might be desired. We feel that if all of this land were to be acquired, presuming that

the coal is there, we would have an investment of approximately $200 an acre. Some of this land might be purchased for $110 to $150 an acre; some may run $200 to $250. You can see from this that we would eventually have an investment of five to six million dollars in land. If this were purchased under a royalty agreement, I think we would still have the same investment because you would have to guarantee a certain royalty. However, the cost to the Company in an operating mine would naturally be reduced. We probably would spend 15 to 20 thousand dollars at least just in acquiring options of this magnitude, and to properly drill this entire area would be an estimate of $300,000. We figure that it would be $ per acre.

We should keep in mind that the land that we now control has a ratio of approximately 20-25 to one, and we naturally would try to obtain the same ratio throughout the No. 2 coal field, if possible, but no doubt to obtain a large tonnage we might go up to 35 or 40 to one readily. We of course will have to get some options in locations other than our present vicinity and get a few drill holes down to give us a better idea.

Also shown on this map in blue color is the property that we understand has been optioned by Ayrshire Collieries. We do not know that they have taken these options but we do know they are active in this field. The outer perimeter or circle covers what we think might be the entire No. 2 coal field. We must understand that in areas now included in our blue lines the coal could be 150-200' deep.

RJH:LJ

Mor. Dep. 32

February 24, 1960

Mr. T. J. Tarry
Mr. J. M. Morris

Springfield

With further reference to your information that the CIPS is very interested in building a power plant near Springfield if cheap coal is available, and asking if we could put anything together in any amounts or volume in this area:

We have done some drilling west of Springfield, which is deep coal, and our drill records do not show the best of roof conditions. However, I would want to check that with people more familiar with it than ourselves. I feel a considerable amount of tonnage could be put together as underground coal west and northwest of Springfield. We would, however, like to go a little further west to see the depth of the coal in that area.

If you think an opportunity might come up, we might get an option further west and get some drill holes which will assist us in spreading out in that area.

R. J. Hepburn

RJH:J

cc: Mr. R. H. Inman
Mr. P. H. Latimer

Mor. Dep. 35

July 17, 1962

Mr. J. M. Morris:

We are informed that there are approximately 12,200 acres of underground coal controlled by O. Stuart Jenkins of St. Louis located about six miles west of Greenville, Illinois. This is the No. 6 seam, having a thickness of 6-7 ft. and being approximately 350-400 ft. deep. We know nothing of the roof conditions nor have we seen any drill logs on this property, but it is for sale at $35.00 per acre.

This immediately joins a Peabody area of approximately the same size that I believe they acquired twenty years ago. Two miles south of this location at Pocahontas this coal was mined up to 1943 - the shaft being 420 ft. deep. Samples taken from this mine in 1921 by the Illinois Geological Survey show thicknesses of 6'8", 7'1", and 7'9", with the following analysis:

Moisture	11.9
Volatile	35.2
Fixed Carbon	42.2
Ash	10.7
Sulfur	3.4
B.T.U.	10,800

This is located between the Nickel Plate, the Burlington, and the Pennsylvania railroads, and Shoal Creek passes through the tract and might have water for a power plant.

I am wondering if you would want us to look into this and see what might be developed.

Morris Dep. Exp. 35
10-1-68
CBS

Mor. Dep. 38

February 3, 1960

Mr. John Davis,
Abraham Lincoln Hotel,
Springfield, Illinois.

Dear Johnny:

Montgomery County, Ill. (Coordinate field)

Sorry I have been so long in getting you some information on the drilling we did on your property. I do not have as yet an analysis from the outside concern. I will advise you of the analysis a little later on.

We did not get quite as many holes as we had hoped to due to weather and sickness. However, we did put down five holes, logs of which and a map are attached, showing the locations. From this drilling and from what coal we have found we feel that your farm would be underlaid with the Springfield #5 coal, the seam averaging approximately 5'-10" in thickness. This coal should run in place 10,000 tons to the acre. By underground methods we figure 60% recovery at the present time, however, with good roof conditions and up-to-date equipment this recovery could be improved. However, we would figure there would be 6,000 clean recoverable tons per acre. Figuring your acres as being 847, which shows on the plat book, you would have around 5¼ million tons of coal in place, and between five or six million tons of washed coal.

While we are not actually in the deep mine business at the present time and are not too experienced in it, we are looking forward to the time when we are underground. From our experience and the drill holes it appears that your roof is not of the best, about 2 feet of slate and 1 foot of rock on most of the holes. A little further study would and should be made on a definite decision. We drilled 90 foot below the first seam of coal and found the #2 coal seam which, however, was very thin and would not be profitable to mine under any circumstances.

I will send you the analysis as soon as it arrives, and while I am not making an offer to you for the coal under your property today I would say that I am interested and I know that you certainly would give me an opportunity in case something would come up in the near future. We want to do some more testing in and around the vicinity and it is possible that we might want to give you an offer someday. I would appreciate it if you would keep this information to yourself and not give it to anyone else. As a rule we do not give the property owner this much information.

Yours very truly,

Vice President

THE UNITED ELECTRIC COAL COMPANIES
307 NORTH MICHIGAN AVENUE
CHICAGO, ILLINOIS 60601

October 27, 1965

Mr. Frank Nugent, President
Freeman Coal Mining Corporation
A Division of General Dynamics Corporation
300 West Washington Street
Chicago, Illinois 60606

Dear Frank:

No doubt you kept a copy of report prepared by your Mr. J. E. Matheson, Jr. on cost estimates to try out underground mining at Fidelity. Estimates were as follows on total cost in trucks in the Fidelity pit:

300 Tons per Shift	$3.077
400 Tons per Shift	$2.610
500 Tons per Shift	$2.385

The attached sheet shows costs accrued in trucks in the pit for the periods indicated.

Our fiscal year ended July 31, 1964 was the best in the history of the Company and Fidelity Mine was in very good stripping and operating conditions and achieved a cost of $1.45¢ for that period. For the period beginning August 1, 1964 and ended December 31, 1964, you will notice a sharp increase in our total stripping cost from 67.1¢ to 89.0¢, and for the nine months ended September 30, 1965, we again went up sharply due to opening the new Green pit, increase in drilling and blasting, and the necessity for operating two machines while we were developing this new pit.

I think a fair estimate of total cost in trucks is probably around $1.80 and this compares with the underground estimate, if we assume a middle-of-the-road basis of 400 tons per shift, of $2.61 in truck. It would appear that a difference of 80¢ per ton is too much to justify trying this method.

We can discuss this further sometime at your convenience.

Yours very truly,

JEMcM

Memorandum to Mr. J. M. Morris:

Re: *TVA Bid—Ruby Underground #9 Seam Mine*

Since talking with you regarding our proposed bid to be opened February 14th, I have talked to both Frank Nugent and Edwin Ruby regarding this proposition.

We had originally planned to put in a contingent bid on a long-term basis to develop this underground coal after the strip mine was exhausted. Later, after discussing this matter further, we felt that it may be best to delay making a bid until the next opening, and, in the meantime we could proceed with an up-to-date cost study to investigate the feasibility of developing this property.

Edwin Ruby says that he would be ready to go into this matter with us at our convenience.

/s/ T. J. Tarzy
T. J. TARZY

cc: Mr. Frank Nugent

P.S. to Mr. Nugent:

I believe you have read the Davis Read report on this property made in 1954. This report showed that there is approximately 6 million tons of recoverable #9 seam coal underlying 1,206 acres controlled by the Ruby-Chandler, Jordan-Moore group.

We can give you a copy of this Davis Read report for your preliminary studies if you so desire.

Mr. G. I. Grasty
Dixie Realty
P.O. Box 4252
Richmond Virginia

Dear Mr. Grasty:

Your letter of November 15th regarding coal lands in West Virginia and Kentucky has been referred to me, and I will be glad to receive full particulars and if possible, maps and any engineering reports you might have on both the coal in West Virginia and Kentucky. Before expressing any interest, it will be necessary for us to have as much information as possible on the names of the seams, thickness and quality of seam, actual areas of coal, in other words, a full and complete description of each property.

As you undoubtedly know, we are primarily engaged in stripping, but we are also interested in underground coal where mining and market prospects are attractive.

Very truly yours,

T. H. LATIMER

Dear John:

I wonder if you would ask your Engineering Department to tell you where and how far the limestone is from the coal, and the thickness of the limestone, in the Round Perry Field.

It would also be helpful to know whether or not you have subsidence waivers. Possibly the Longwall System could be used in mining the coal.

Yours very truly,

FRANK NUGENT
President

GOVERNMENT EXHIBIT Mor. Dep. 59

Mr. Robert S. Overbeck, General Manager
Aluminum Company of America
1501 Alcoa Building
Pittsburgh 19, Pennsylvania

Dear Mr. Overbeck:

It was a pleasure to meet with you and Phil Dorrance on November 14th to discuss our mutual interests in the coal reserves being put together in Perry County, Illinois.

In looking back through our files I find it was on September 1, 1960 that Mr. Morris, Mr. Sherrill and I met with the following Alcoa people:

B. J. Fletcher
H. C. Erskine
J. D. Harper
B. H. Sloane
H. R. Althauser
Roy F. Miller

and it was at this meeting that two of the subjects discussed were -

(a) When Alcoa wishes to make use of the coal in Beaucoup Field for its own purpose, United Electric would like to have prior consideration for the mining operation on a basis to be decided on at that time, and

(b) Should United Electric have the opportunity to make use of the coal in Beaucoup Field for a consumer other than Alcoa, for instance, an electric generating station, we would like for Alcoa to agree to allocate up to, say, 50 million tons, to United Electric for that purpose. A method of payment for the coal could be worked out at that time, and at the same time the area from which the coal could be produced would be designated.

The total tonnage in situ for the field should be well over 200 million tons.

In general these are the two areas in which there was agreement and we should like to have acknowledgment in writing that Alcoa concurs in this understanding.

We have also given some thought to the idea that Alcoa might like to lease up to 50 million tons to United at the present time in an area and at a price to be mutually agreed upon. Such an arrangement would permit United to include the tonnage as reserves. We shall appreciate your comments on this.

Again thanking you for your courtesy, and with kind regards.

Sincerely yours,

Secretary

Mr. G. H. Utterback
Secretary
The United Electric Coal Companies
307 North Michigan Avenue
Chicago 1, Illinois

Dear Mr. Utterback:

Thank you for your letter of November 29. As I informed you at our meeting on November 14, I am relatively green on the subject of past understandings between our two companies and, therefore, agree with you that any such understandings should be clarified for the future by an exchange of letters. Consequently, I have discussed your letter with those still available who were present at the meeting on September 1, 1960 and particularly with Mr. Roy F. Miller.

Generally speaking, Alcoa's purpose in going into the Beaucoup Field was to acquire a coal reserve in a favorable location with no strings attached. Keeping this in mind, we do not know of any commitments made by Alcoa to United Electric other than those spelled out in our written agreements, but we do acknowledge the follow understandings:

(a) When Alcoa wishes to make use of the coal in the Beaucoup Field for its own purposes, United Electric will be given serious consideration for undertaking the mining operations on a basis to be decided on at that time, and

(b) At any time that United Electric should come up with a specific proposition for leasing part of the coal in the Beaucoup Field, Alcoa is willing to consider seriously such a lease.

Although our wording of these understandings varies somewhat from yours, it represents our considered opinion of what was discussed at the meeting of September 1, 1960.

Kolbe Dep. U.S. 10-28-68 and Morris Dep. Ex. 60 10-1-68

As regards the next to last paragraph in your letter, under Item (b) above, we will be glad to give serious consideration to any specific proposal that you might make at a time and place to be suggested by you.

We would appreciate your comments, but hope that the above is satisfactory and that you will confirm it in writing.

With best personal regards.

Sincerely yours,

R. S. Overbeck

AGREEMENT

WHEREAS, the relationship between ALUMINUM COMPANY OF AMERICA and THE UNITED ELECTRIC COAL COMPANIES, respecting certain property located in Perry County, Illinois, has been governed by a certain Agreement entered into by the parties September 5, 1956, and

WHEREAS, the said Agreement of September 5, 1956, has subsequently been amended by the letter agreement between the parties dated August 20, 1957, by another letter agreement dated January 27, 1960, and by a third letter agreement between the parties dated March 23, 1960, and

WHEREAS, the said parties to the above Agreement dated September 5, 1956, are desirous of both adding certain additional matter to this Agreement as amended and also of consolidating the above Agreement and its amendments into one document,

NOW, THEREFORE, THE UNITED ELECTRIC COAL COMPANIES, a Delaware corporation, having its principal office in Chicago, Illinois (hereinafter called "United") and ALUMINUM COMPANY OF AMERICA, a Pennsylvania corporation, having its principal office in Pittsburgh, Pennsylvania (hereinafter called "Alcoa"), intending to be legally bound, do hereby agree and covenant as follows in this AGREEMENT, made and entered into at Pittsburgh, Pennsylvania, this 3rd day of May, 1965.

1. United and Alcoa agree that this AGREEMENT shall supersede and replace the Agreement between the parties dated September 5, 1956, as amended by letter agreements dated August 20, 1957, January 27, 1960, and March 23, 1960, but shall not modify, alter, or release any of rights or duties which have heretofore arisen under the said Agreement as amended and which have not been fully performed or fulfilled.

2. In the course of performing the obligations contained in Articles 3, 4, 5, 6, 9, 10, 11, 12, 13, 14, and 15, and in all dealings with others not a party to this AGREEMENT, United shall act in its own name and without disclosing that it is acting for Alcoa.

3. United, acting in good faith and with reasonable diligence, shall undertake to obtain recordable and assignable options for the purchase of the coal and coal mining rights, together with all other available minerals and mineral and mining rights, in at least Eighteen Thousand (18,000) acres but not more than Twenty-Five Thousand (25,000) acres of land located east and north of Pinckneyville, Perry County, Illinois as outlined in red on the map marked "Exhibit A" and attached hereto, paying to the owner or owners of said land as consideration for each option so obtained the sum of One Dollar ($1.00) per acre of land. United shall, insofar as is practicable, obtain said options in such a manner that the optioned tracts of land will be contiguous and constitute a solid block.

4. Until otherwise directed by Alcoa, each option so obtained shall be in the form marked "Exhibit B", attached hereto, and shall provide for payment of a total purchase price to the optioner or optionors not to exceed Fifty Dollars ($50.00) per acre of land.

5. Whenever United, acting pursuant to the provisions of Article 3 hereof, shall be unable to obtain an option to purchase the coal underlying any tract or tracts of land within the area outlined in red on "Exhibit A", it shall undertake to obtain a recordable and assignable lease of coal and coal mining rights with respect to said tract or tracts of land in the form marked "Exhibit C" and attached hereto.

6. United shall without undue delay cause each option and each lease obtained to be recorded in the appropriate records of Perry County, Illinois.

7. Immediately after each option or lease has been recorded, United shall convey, assign, and deliver each such option or lease to Alcoa or to such other person or corporation as Alcoa shall in writing nominate or appoint, without recording such conveyance or assignment.

8. United does hereby acknowledge and declare that it will hold

the leases, options, deeds, titles, properties, and interests obtained pursuant to this AGREEMENT in trust for Alcoa; that it will continue to hold any leases, options, deeds, titles, properties, and interests obtained pursuant to the Agreement dated September 5, 1956, in trust for Alcoa; and that United will not claim to have any right, title, or interest in any of said leases, options, deeds, titles, properties, or interests.

9. Unless otherwise notified by Alcoa, United shall give extension notices as provided for in each and every option agreement, and at the same time, shall pay to the respective optionors the consideration required by the option agreements. The extension notices will be in such form as Alcoa may prescribe. At the time of delivery of the notice of extension and payment of consideration, United shall obtain the optionor's written acknowledgment of receipt of notice and payment of consideration.

10. Unless otherwise notified by Alcoa, United shall make annual payments as provided for in each and every lease obtained pursuant to Article 5 hereof, and at the same time, shall obtain the lessor's written acknowledgment of receipt of payment.

11. Upon Alcoa's request, United shall procure abstracts of title to the properties leased pursuant to Article 5 hereof, deliver these abstracts to title examiners designated by Alcoa, and assist in work reasonably necessary to curing any and all defects in the title to these properties.

12. Whenever Alcoa shall so request, United shall cause the optioned or leased properties to be properly drilled on approximately one-half mile centers and shall cause the cores to be examined and logged by a competent consulting engineer. United shall cause the coal samples to be analyzed by Commercial Testing Laboratory in Chicago, Illinois and shall promptly deliver to Alcoa the results of such analysis.

13. Unless otherwise notified by Alcoa, United shall take such steps as are necessary to exercising the options immediately prior to their

respective expirations and to taking good title of record to the coal and other interests previously optioned. In connection with the performance of this work, United hereby agrees to perform, upon Alcoa's request, such other work as is necessary or convenient to carrying out these purposes, such as but not necessarily limited to the procuring of abstracts, the delivering of these abstracts to title examiners designated by Alcoa, and the assisting in work reasonably necessary to cure any and all title defects. Thereafter, United shall convey these interests so obtained to Alcoa by deeds of special warranty without recording said deeds.

14. After United has conveyed the titles or assigned the leases to Alcoa as provided herein, United agrees that it shall continue to act as if it were the owner of all these interests so conveyed or so assigned until otherwise notified by Alcoa. In accordance with the foregoing it shall manage the properties, list the properties for taxes with the appropriate authorities, pay all taxes and charges accruing with respect thereto, and take any and all other steps as are reasonably incident to the ownership of the property and necessary to the maintenance of good title thereto.

15. Upon United's receiving notice of an application for a permit to prospect for oil and gas through any of the properties covered by this AGREEMENT, or on the surface above these properties, it promptly shall so notify Alcoa. Thereafter, United shall take such action with respect to preventing the issuance of a drilling permit to the applicant as Alcoa shall request.

16. On or before the tenth day of each month, United shall invoice Alcoa for, and Alcoa shall thereafter promptly pay, such charges as shall be due and owing to United by Alcoa on account of performance hereunder by United during the previous month. Such charges shall consist of the following:

A. Payments made by United to the optionor or optionors

pursuant to the provisions of Articles 3, 9, and 13 hereof;

B. Payments made by United to the lessor or lessors pursuant to the provisions of Articles 5 and 10 hereof;

C. Payments made by United for salaries and wages of persons employed by United solely for the purpose of performing the agreements contained in Articles 3 and 4 hereof;

D. Payments made by United for fees in connection with the recording of options and leases pursuant to Article 6 hereof, and with the recording of deeds pursuant to Article 13 hereof;

E. Payments made by United to satisfy obligations imposed with respect to the properties held in accordance with Article 14, including but not necessarily limited to taxes and assessments imposed thereon;

F. Payments made by United for fees in connection with objecting to the issuance of a permit to drill for oil and gas through the properties covered by this AGREEMENT, or on the surface above these properties, as may arise pursuant to the provisions of Article 15 hereof;

G. An amount which is equal to one and one-half times the portion of the salaries of United's engineering and land acquisition employees which is attributable to United's performance of the agreements contained in this AGREEMENT on the basis of actual time spent by such employees in performance thereof;

H. The actual cost to United of drilling, examination and logging of cores, and analysis of samples performed pursuant to Article 12 hereof; and the actual cost of procuring such abstracts as shall be purchased by United pursuant to Articles 11 and 13 hereof;

I. Expenses incurred for meals, lodging, transportation, telephone and telegraph messages, engineering supplies and office supplies.

17. United shall, upon being so notified by Alcoa at any time, immediately cease, or temporarily suspend, the obtaining of either options, or leases, or both, pursuant to this AGREEMENT.

18. This AGREEMENT may be terminated by either United or Alcoa by giving thirty (30) days prior written notice of such termination.

19. In the event Alcoa decides not to extend any of the options, or not to exercise any of these options, or to abandon any of the leases acquired under this AGREEMENT, the said options or leases shall at the election of United be reassigned by Alcoa to United upon the reimbursement by United to Alcoa of all charges theretofore paid by Alcoa to United with respect thereto as provided in either Article 16 hereof or Article 6 of the Agreement dated September 5, 1956, or both, plus any payments made on any of said properties by Alcoa prior to September 5, 1956.

20. United has previously obtained and assigned to Alcoa certain options enumerated and described on Schedule A, attached hereto, covering lands lying only partly within the area outlined in red on Exhibit A. As to the options shown on Schedule A, notwithstanding anything to the contrary in other Articles of this AGREEMENT, United and Alcoa agree as follows:

(a) Alcoa shall reassign to United the options shown on

Schedule A, and United shall hold each such option and cause it to be renewed, assigned, exercised or allowed to expire as herein provided.

(b) Until otherwise agreed to in writing by United and Alcoa, United shall cause each option shown on Schedule A to be kept in force by timely giving all renewal notices and paying all renewal charges therein allowed or required. When any such option is renewed and renewal charges have been paid by United as herein provided, United shall give Alcoa notice thereof, and Alcoa shall reimburse United for Alcoa's share of such renewal charges, which share is agreed to be the amount shown under "Alcoa Renewal Cost/Year" on Schedule A.

(c) If at any time either United or Alcoa shall desire that any such option be allowed to expire, it shall so notify the other in writing and the party receiving such notice shall, within 10 days thereof, in writing, notify the party giving such notice whether it agrees with or dissents from allowing such option to expire.

(1) If the notices of United and Alcoa agree that such option be allowed to expire, no renewal payment shall be made and the option shall be allowed to expire.

(2) If Alcoa gives United notice that Alcoa desires that such option be allowed to expire and United gives Alcoa notice that United dissents from allowing such option to expire, all rights of Alcoa in and to such option shall terminate and United shall thereafter hold such option for its sole account

and shall reimburse Alcoa for all option payments and renewal payments relating to such option for which Alcoa has reimbursed United pursuant to this agreement or pursuant to the agreement of September 5, 1958.

(3) If United gives Alcoa notice that United desires that such option be allowed to expire and Alcoa gives United notice that Alcoa dissents from allowing such option to expire, United shall cause such option to be renewed by timely giving all renewal notices and paying all renewal charges therein allowed or required. Forthwith after such renewal United shall assign such option to Alcoa and Alcoa shall reimburse United for the renewal payment made pursuant to the preceding sentence and for all option payments and renewal payments theretofore made by United on account of such option for which Alcoa has not reimbursed United.

(d) If, during the term, or any renewal term, of any option shown on Schedule A, either United or Alcoa shall desire the exercise of such option, it shall so notify the other, in writing, and the party receiving such notice shall, within 10 days thereof, in writing, notify the party giving such notice whether it agrees with or dissents from such exercise.

(1) If the party receiving notice agrees with the exercise, United shall proceed to exercise the option and complete the purchase of the land described therein. Promptly after the conveyance to United of the land

described in such option, United shall, by deed of general warranty, convey to Alcoa that portion of said land shown under "Alcoa Area Description" on Schedule A and Alcoa shall reimburse United for the purchase price paid by United for such portion.

(2) If the party receiving the notice dissents from the exercise, United shall proceed to exercise the option and complete the purchase of the land described therein. If the option is exercised and the land purchased at the instance of United and without the assent of Alcoa, United shall acquire and hold the land at its sole expense and for its own account and shall reimburse Alcoa for all option payments and renewal payments relating to such option for which Alcoa has reimbursed United pursuant to the aforementioned agreement of September 5, 1956, or pursuant to this agreement. If the option is exercised and the land purchased at the instance of Alcoa, and without the assent of United, United shall, by deed of general warranty, promptly convey the land described in such option to Alcoa, and Alcoa shall reimburse United the total purchase price now provided in such option less the total of all option payments and renewal payments relating to such option for which Alcoa has reimbursed United pursuant to the aforementioned agreement of September 5, 1956, or pursuant to this agreement.

21. All notices and requests provided for in this AGREEMENT shall be in writing. Notices to United shall be deemed to be properly given

Chicago 6, Illinois

Dear Frank:

Enclosed is copy of letter from Ray Miller of Alcoa which I thought you would like to see.

In line with our recent discussion, it appears worth while to make a study of possible investment and cost per ton that might be achieved in an underground mine on the coal acreage that has been acquired by the Aluminum Company.

There is, of course, no hurry about this but whenever you would like to do it, please let us know what information is needed and we will supply it.

With kindest regards,

Yours very truly,

Johnnie

June 11, 1962

Morris Dep. Ex. 70
CBS 10-1-68

Mr. Francis Stanley Jordan
37 Jefferson Avenue
Short Hills, New Jersey

Dear Mr. Jordan:

This will acknowledge yours of June 7. Permit me to welcome you as a stockholder in our company and we appreciate your interest as expressed concerning recommending the purchase of United Electric stock for some others.

For our fiscal year ended July 31, 1961, approximately 62% of our sales was to the utilities. For our current year ending July 31, 1962, we anticipate this will increase to 70% or maybe slightly more.

We continue to share in the growth of the utility industry. Most of our utility customers are under long-term contracts with us, varying in number of years. All of these contracts carry escalation clauses covering changes in wage rates, costs of materials and supplies, hours of work per day or week, and changes in Federal or State laws having a direct effect on production costs.

We do not have any serious competition in the Midwest from oil for use in industrial and utility plants. We do have severe competition from natural gas when it is dumped at low prices during the summer months when there is no heating load. We feel, however, that with our mining methods and transportation costs, we can continue to hold our position with this competition. It is expected that with the diminishing reserves of gas and the possible higher prices, our competitive relationship with this fuel will improve.

We are glad to hear from you and if any further information is desired, please call on us.

Sincerely,

JCC:EF

Mr. J. H. Taylor

Re: Illinois Power, Vermilion-Danville Power Plant

In recent discussions with Arch Krambrik, he mentioned that they are seriously considering the matter of stripping the coal that they own adjacent to their Vermilion power plants.

He stated that they have estimated that there is 6,000,000 tons that could be strippable in this area and that Armstrong had made them a proposition to strip this coal [illegible] them at a certain cost and deliver it to their power [illegible].

Arch recalled that we went into this situation some time ago and he would like to have us renew our efforts along those lines and come up with a cost and delivered figure for them to this coal.

I have mentioned this to Mr. Rayburn and I am sure [illegible] will want to discuss it with him on your return to the [illegible] and then contact Arch about it.

D. J. Payne

GENERAL SERVICES ADMINISTRATION
FEDERAL SUPPLY SERVICE

TERM CONTRACT ORDERING DATA FOR:

FSC Group 91 Fuels
FSC Class 9110 — Coal

Veterans Administration Facilities
(Schedule 1)

&

Federal Public Buildings
(Schedule 2)

Within the states of:
Illinois, Indiana, Kentucky, Michigan, Ohio & Wisconsin

GEOGRAPHIC COVERAGE:

Effective Period:
Date of Award through June 30, 1968

IMPORTANT NOTICE

In addition to the "Special Provisions" below, Contractors listed herein are subject to the provisions of the following forms, which are a part of the Contract:

(a) General Provisions (Supply Contract) Standard Form 32, June 1964 Edition.

(b) Standard Form 33 & 33A, December 1964 Edition.

(c) Supplemental Provisions, GSA Form 1424, September 1964 Edition.

(d) PS Form T288, October 1965 "Equal Opportunity."

(e) Special Provisions Applicable to Coal Contracts dated March 9, 1951.

SCOPE OF CONTRACT

This schedule provides for the normal supply requirements of the installations specified herein, and contracts will be used as primary sources for the articles or services listed herein. Articles or services will be ordered from time to time in such quantities as may be needed. As it is impossible to determine the precise quantities of different kinds of articles and services described in the schedule that will be needed during the contract term, each Contractor will be obligated to deliver all articles and services of the kinds contracted for that may be ordered during the contract term, EXCEPT:

(a) EXIGENCIES: In cases of exigency. (Subject to audit by the General Accounting Office.)

(b) URGENT REQUIREMENTS: To the extent that a contractor is unable to meet the bona fide delivery requirements of ordering activities STIPULATING DELIVERIES SHORTER THAN THE CONTRACT DELIVERY TIME. Delivery requirements are defined as actual needs of the ordering office which require the articles or services must be delivered in the total quantity required by the date required. When the contract delivery time does not meet delivery requirements and the ordering activity determines that time permits, the Contractor shall be requested by letter, telegram or telephone (confirmed in writing) to state the best delivery time of which he is then capable. The Contractor shall reply to such inquiries in kind not more than 3 working days after receipt. Orders placed on the basis of a shorter delivery time agreed to shall be delivered within this shorter delivery time and in accordance with all other terms and conditions of the contract.

SPECIAL REQUIREMENTS

Where an agency included under Scope of Contract Provision finds that the specific articles or services listed herein will not meet a special requirement, articles or services having the same general characteristics needed to meet the special requirement may be procured: Provided, that a prior written waiver of the requirement for using this schedule is obtained from the General Services Administration. Requests for such waivers shall be submitted to the contracting office at the address shown on the face of the Schedule. Such requests shall (a) describe the pertinent differences between the articles or services listed herein and those required, (b) specify the quantities required, and (c) state the reasons why the articles or services listed herein will not meet the requirement.

(Continued)

SUPPLEMENTAL & SPECIAL PROVISIONS

PURCHASE ORDERS: Purchase or delivery orders will be issued to the coal contractor by the activity concerned in accordance with the schedule. Upon receipt of a purchase or delivery order, the contractor shall furnish the coal specified in the schedule in accordance with the provisions of the contract and in compliance with the instructions set forth in the order. The order should indicate to which office the contractor's invoices are to be submitted for payment. If the coal is to be shipped in a certain type of railroad car or delivered by a designated railroad to a particular yard or siding, such information should be furnished the contractor.

RAIL DELIVERIES: When necessary to meet unloading conditions, the government reserves the right to require shipments to be made in the type of transportation equipment it may specify and to reject shipments proffered in other types of equipment.

PRICES: (a) Prices "FOB MINE (CARS)" -Free on Board Cars, at the mine or at the water front dock.
(b) Prices "FOB DESTINATION (Tracks)" - Includes transportation costs to rail siding at destination. Drayage from railroad siding to bin to be arranged by ordering office.
(c) Prices "DELIVERED INTO BINS" - Includes delivery into the bins at the using activity without additional cost to the government.

Seller's Invoices: Paragraph 11 of Standard Form 33-A is hereby corrected to read "Invoices shall be prepared and submitted in original only, etc.," in lieu of "in Quarduplicate." The rest of the paragraph remains the same.

SPECIFICATION:
The Federal Activity and destination (delivery), the size of coal, the analytical constituents (limits) and estimated tonnage, by item numbers, are given in the Schedule. The sizes specified are based on round hold screen. Unless otherwise specifically stated for an item, the coal is for use as fuel in heating or steam generating plants. Coal which is unduly friable, oxidized, non-caking or non-coking, will not be acceptable.

SUPPLEMENTS TO SPECIAL PROVISIONS APPLICABLE TO COAL CONTRACTS DATED MARCH 9, 1951.

"PRICE REVISION - OTHER THAN RETAIL" - Paragraph 10 is supplemented as follows:

"The aggregate of the increases in any unit price made under this paragraph shall not exceed 10 percent of the original applicable price."

"PRICE REVISION - RETAIL - Paragraph 11 is supplemented as follows:

"The aggregate of the increases in any unit price made under this paragraph shall not exceed 10 percent of the original applicable price."

"VARIATION OF TONNAGE" - Paragraph 12 is supplemented as follows:

"Unless otherwise specified, any variation in the quantities called for in any order, not exceeding 10 percent, will be accepted when caused by conditions of loading or shipping."

VETERANS ADMINISTRATION FACILITIES

(SCHEDULE NO. 1)

ADDITIONAL REQUIREMENTS AND SPECIFICATIONS

Contractors who received awards on a delivered and stored basis will be required to place the coal on the stockpile or into coal hoppers as required by the installation.

On awards made f.o.b. mine, movement by rail will be made on commercial bills of lading, which will be converted to Government bills of lading at destination. Further instructions will be furnished in notices of acceptance and in purchase orders placed under the contracts.

Deep Mined Co[illegible]

No. 6 Seam in Southern and Centr[illegible]

distinguished for their basic character and excellent preparation for electric utility, industrial, metallurgical and heating uses

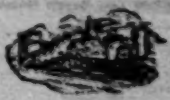
ORIENT NO. 8

Shipping point Orient Mine No. 3, Illinois. Daily capacity 14,000 tons. One of the largest mines in the country. Famed for quality and excellence of preparation. The lowest ash low sulphur coal in Illinois for metallurgical, electric utility, industrial and heating applications. Extensive reserves.

ORIENT NO. 4

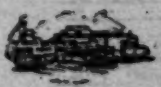
Shipping point Orient Mine No. 4, Illinois. Daily capacity 7,000 tons. A special feature of this mine is its attractive glossy-black, firm structure coal, unusually low in moisture and high in Btu content. A popular dealer coal as well as a long-time favorite with utilities and industries.

ORIENT NO. 5



Shipping point West Frankfort, Illinois. Daily capacity 7,000 tons. Freeman's newest mine, highly automated for unusually precise control of both quality and sizing. Orient No. 5 coal is a low moisture, high Btu product, highly desirable for utility, industrial and heating uses.

CROWN MINE



Shipping point Crown, Illinois. Daily capacity 10,000 tons. The largest air-cleaning plant in the country plus unusually versatile preparation facilities capable of meeting varied market requirements. Crown coal is widely used by utilities and industries, and also has a large and loyal dealer following.

UNITED ELECTRIC COALS
for Electric Utilities and Basic Industries

by Barge on Inland Waterways
by Rail to Middle West Points
by Truck for Local Area Delivery

BANNER MINE PEORIA COUNTY, ILLINOIS

Shipping point Banner, Illinois. Banner No. 2 Seam. Daily capacity 4,000 tons. A direct barge-loading mine, producing heavy medium washed coal for commercial, industrial, and heating markets.

FIDELITY MINE PERRY COUNTY, ILLINOIS

Shipping point Pinckneyville, Illinois. No. 6 Seam. Daily capacity 8,000 tons. An unusually versatile preparation plant producing required sizes of washed and heat-dried coal.

BUCKHEART MINE FULTON COUNTY, ILLINOIS

Shipping point Canton, Illinois. No. 5 Seam. Daily capacity 9,000 tons. A heavy medium preparation plant with its own rail facilities to transport coal to barge-loading dock at Liverpool.

CUBA MINE FULTON COUNTY, ILLINOIS

Shipping points Cuba and Lewistown, Illinois. No. 5 Seam. Daily capacity 4,500 tons. Produces high quality washed and heat-dried coals primarily for electric utilities and industries.

Re: United States v. General Dynamics, et al.

Dear Mr. Cusack:

Enclosed herewith is a statement, compiled from the stock records of The United Electric Coal Companies showing the amount of dividends paid by UEC to Material Service Corporation, General Dynamics Corporation and Freeman Coal Mining Corporation for the period January 1, 1950 to December 27, 1967.

We understand that this is the information requested by Paragraph 18 of your draft motion for production of documents and our conference on December 11, 1967.

Very truly yours,

Reuben L. Hedlund

PRESIDENT'S LETTER TO STOCKHOLDERS

1964 was a very good year for your Company, as you will see from the following pages. Good operating conditions at all of our mining properties contributed substantially to the results. Increased sales to our customers made it possible to produce a record of 5,562,886 tons. Details of the year's results are presented under "Review of the Year."

Wherever possible, we continue to reclaim land which has been mined and put it to the use for which it is best adapted. Color photographs on the cover of this report show some of the recreational facilities that have been established and are being used.

Most of the responsible strip coal mine operators are doing this. The enclosed brochure produced by the Mined Land Conservation Conference shows the variety and extent of land reclamation activities in many states. Your Company is a member of the Conference and contributes both time and money as well as the talents of our organization to this work.

The coal industry must continue to support every effort to maintain and increase its proportion of the energy market. This will require the use of every means of reducing mining costs and the full cooperation of all transportation agencies to achieve the lowest possible delivered costs at point of use. We believe that our competitive position can be maintained in the territory served by your Company.

Approximately 60% of our production is shipped via the inland waterways. Railroads are making a determined effort to compete with water-borne coal and substantial reductions in their freight rates have been made in recent months. We continue to watch this development closely and endeavor to retain our competitive relationship in the market areas served by our mines.

Sales and production at all of our properties continue currently on a very satisfactory basis and we are optimistic about the future of the coal industry.

We have always had the full and sincere cooperation of our entire organization and we are grateful to our shareholders, members of our Board of Directors, and all employes for their interest and efforts on behalf of the Company.

Respectfully submitted,

John M Mem

President

September 11, 1964

New heat dryer unit at Fidelity Mine reduces moisture content of the coal and [illegible]

REVIEW OF THE YEAR

Sales of the Company were the highest on record – $22,391,226. Net income was $3,233,343, equivalent to $4.80 per share. Progress over the past ten years is shown on Page 12 and inside back cover of this Annual Report.

At the end of our fiscal year 1963, bank loans amounted to $1,708,199 and all of this was retired during the year ended July 31, 1964.

The dividend rate of $1.60 per share annually was continued throughout the past year.

CAPITAL ADDITIONS A new heat dryer was installed at the Fidelity Mine and started operating in February of 1964. This dryer removes the excess moisture from the washed coal, increasing the heating value and avoiding the extreme difficulties of unloading frozen coal in severe winter weather. Prior to the installation of the dryer, our shipments from Fidelity Mine were seriously curtailed during extremely low temperatures and this will now be avoided. The dryer has performed in a very satisfactory manner and completely in accord with our expectations.

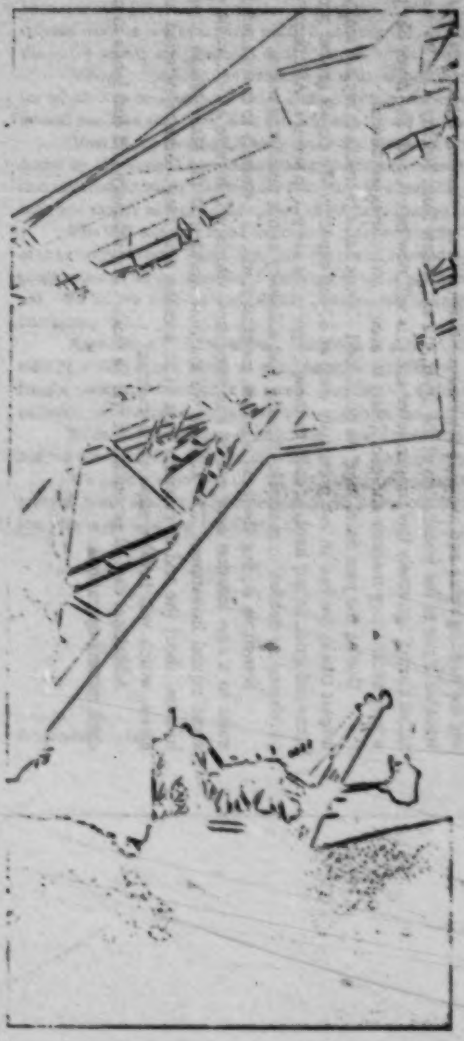
During the past fiscal year, we purchased 100-ton haulage trucks to replace smaller units. The largest trucks we had in use previously were of 60-ton capacity. We expect greater production and some reduction in our haulage costs as these larger units are put in service. Additional units will be purchased as needed to maintain capacity and efficiency at our producing mines.

Sometime during the next eighteen months, it will be necessary to move some heavy equipment to a new location near one of our properties, which will involve considerable expense and some capital investment. The acreage we are now working at the Mary Moore Mine will be exhausted about the end of calendar year 1964 and the equipment there transferred to other properties, which will involve expense in moving.

Additional capital expenditures will be made for machinery and coal lands to maintain efficient mining operations.

1778

PRODUCTION OF UNITED ELECTRIC COALS

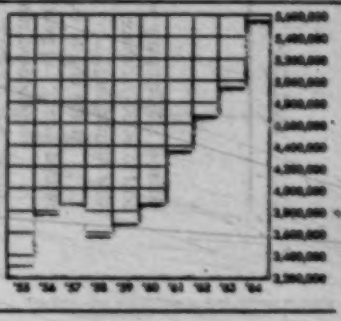


As indicated below, our production has continued to grow year by year, showing an increase of 12¼ % for the year ended July 31, 1964 over the previous fiscal year ended July 31, 1963.

BY MINES—TONS

		1963
Cuba	840,871	804,980
Buckheart	1,848,864	1,330,455
Fidelity	1,899,040	1,904,447
Banner	717,094	008,158
Mary Moore	983,937	395,583
	5,588,868	4,946,583

BY YEARS—TONS

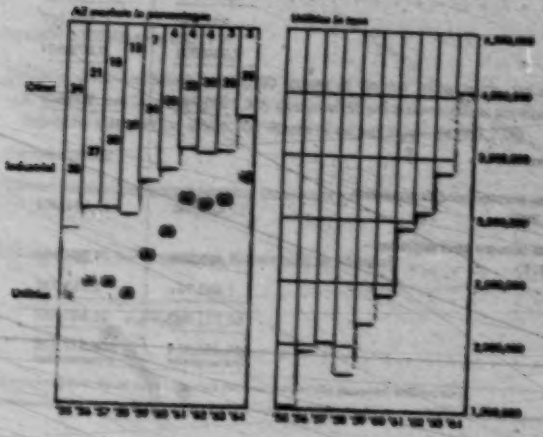


COAL DEPOSITS At the year end July 31, 1964, our total recoverable tonnage was 143,400,000 tons, of which 95,500,000 tons are suitable for mining by the strip method and 48,900,000 tons of underground coal. During the fiscal year, we added to our available strip acreage just about the amount produced by all of our mines.

CHANGE IN FISCAL YEAR For some time it has appeared desirable to change our fiscal year end from July 31 to December 31. This will make it easier to comply with the requirements of various governmental bureaus and to compare results of the Company with those of other coal producers and industries. The change was authorized by the Board of Directors during the past fiscal year. The interim statement for the five months period ending December 31, 1964 will be sent to our shareholders and also incorporated in our Annual Report for the calendar year 1965, which will be our next fiscal year.

PERSONNEL Without loss of working time, an amended wage agreement was negotiated last spring with the United Mine Workers of America whereby wages were increased $1.00 per day on April 2, 1964 and an additional $1.00 per day on January 1, 1965. Vacation pay was increased from $200 to $225 beginning with payments in June, 1964. The new agreement is terminable on sixty days' notice by either party on or after March 31, 1968.

CONSUMPTION OF UNITED ELECTRIC COALS



Practically our entire increase in sales last year occurred in shipments to public utilities. 75% of our production was sold in this market, 18% to industrial consumers, and the balance of 3% to others. We continue to direct our sales efforts toward maintaining and increasing our proportion of the utility and industrial market.

Earned Surplus at End of the Year	$19,244,885	$16,921,466

NOTES

1. INVESTMENTS Included in investments is the cost, $730,000, of the Company's investment in capital stocks of affiliates engaged in barge operations. The Company's equity in the combined net assets of these affiliates at the close of their fiscal year exceeded its investments therein. These barge affiliates had loans of $3,483,245 at July 31, 1964 and the owners of these affiliates in effect guarantee that the revenues will be sufficient to repay the instalments of these loans. In connection with such guarantee, the Company has also agreed to maintain working capital of $1,750,000. At July 31, 1964, the Company had working capital of $5,559,958.

2. INVESTMENT CREDIT Investment credit applicable to prior years, which had been treated as a reduction of property at July 31, 1963, has been reversed in 1964 and credited to earned surplus.

3. COMMITMENTS At July 31, 1964, the Company had commitments of approximately $2,450,000 for advance royalty payments on long-term coal leases and $950,000 for future payments on option contracts to purchase coal lands, of which approximately $850,000 is payable in the twelve months ending July 31, 1965.

ACCOUNTANTS' REPORT

THE UNITED ELECTRIC COAL COMPANIES:

We have examined the balance sheet of The United Electric Coal Companies as of July 31, 1964 and the related statement of income and earned surplus for the year then ended. Our examination was made in accordance with generally accepted auditing standards, and accordingly included such tests of the accounting records and such other auditing procedures as we considered necessary in the circumstances.

In our opinion, the accompanying balance sheet and statement of income and earned surplus present fairly the financial position of the Company at July 31, 1964 and the results of its operations for the year then ended, in conformity with generally accepted accounting principles applied on a basis consistent with that of the preceding year.

GENERAL DYNAMICS CORPORATION
ONE ROCKEFELLER PLAZA
NEW YORK, N. Y. 10020

INVITATION FOR TENDERS
OF COMMON STOCK OF
THE UNITED ELECTRIC COAL COMPANIES
AT $50.00 PER SHARE

To the Holders of Common Stock of
THE UNITED ELECTRIC COAL COMPANIES:

General Dynamics Corporation ("General Dynamics") invites the holders of Common Stock of The United Electric Coal Companies ("UEC"), upon the terms and conditions set forth in this Invitation, in the enclosed Form of Tender and Assignment and on the reverse thereof, to tender shares of Common Stock of UEC for purchase by General Dynamics at the price of $50.00 per share in cash, net to the seller. No charges for brokers' commissions or state transfer taxes will be made to stockholders of UEC for transfer of their shares to General Dynamics.

General Dynamics will pay to any member of a registered national securities exchange or of the National Association of Securities Dealers, Inc. whose name appears on the Form of Tender and Assignment as soliciting broker a fee of 50¢ per share for each share tendered thereby and purchased pursuant to this Invitation for Tenders.

This offer expires at 5:00 p.m., Eastern Daylight Saving Time, on Tuesday, October 25, 1966, and tenders must be received at the office of The Chase Manhattan Bank (National Association), Tender Agent, 80 Pine Street, 2nd Floor, New York, N. Y., on or before said date, provided, however, that General Dynamics may, at its option, by notice to the Tender Agent, extend the period for tenders from time to time until not later than Monday, November 21, 1966.

If 170,000 or more shares are properly tendered prior to the expiration of the initial or extended tender period, General Dynamics will be obligated, subject to the conditions hereof, to purchase all shares tendered.

Whether or not the period for tenders is extended, if less than 170,000 shares are tendered during the period within which tenders may be made, General Dynamics is not obligated to purchase any of the shares tendered, but it reserves the right to purchase all or any part of the shares tendered. If General Dynamics purchases fewer than all such shares tendered, purchases will be prorated and the same proportion of shares will be purchased from each tendering stockholder (except that, in the event that proration of shares tendered will result in a return of ten shares or less to any stockholder, General Dynamics reserves the right to retain and purchase all such shares). Any proration will be effected in such a way as to eliminate the purchase of fractional shares.

All tenders are irrevocable until the shares are purchased or returned as provided in this Invitation for Tenders. In order to take advantage of this offer stockholders of UEC should act promptly. You should either:

1. Send the enclosed Form of Tender and Assignment properly filled out, executed and accompanied by your stock certificate(s) and any necessary supporting documents, as set forth in the instructions on the reverse of the Form of Tender and Assignment, to The Chase Manhattan Bank (National Association), Corporate Agency Department, 80 Pine Street, 2nd Floor, New York, N. Y. 10015 (registered mail is suggested); or

2. Request your broker or bank to complete the transaction for you.

GOVERNMENT EXHIBIT Bldg. Dep. 35 b

Payment for shares purchased pursuant to this invitation will be made promptly after expiration of the tender period. General Dynamics reserves the right to reject any alternative, conditional or contingent tenders.

At December 31, 1965, directors of UEC as a group owned 2,400 shares of Common Stock of UEC; such directors are eligible to participate in this offer.

General Dynamics owns 445,773 shares of Common Stock of UEC, which is 66.15% of the outstanding shares. General Dynamics first acquired ownership of UEC shares through its acquisition on December 31, 1959 of Material Service Corporation, which then owned 232,303 such shares. Since that date General Dynamics has from time to time acquired 213,470 additional shares, either on the open market or by privately negotiated purchases, at prices ranging from $31.125 to $50.50 per share and averaging $45.83 per share.

If General Dynamics acquires 165,000 shares or more of UEC Common Stock it will own in excess of 90% of the outstanding stock of UEC, and presently intends to acquire complete ownership of the business of UEC. Under the laws of Delaware, in which UEC is incorporated, a corporation owning 90% or more of the shares of another corporation may merge the latter into itself by filing a certificate of ownership and merger authorized by the board of directors of the parent corporation. If such action is taken the certificate would specify the cash or other consideration to be paid upon the surrender of the shares held by the minority. Any stockholder objecting to such a merger and demanding payment for his stock as provided in Section 253(e) of the Delaware General Corporation Law would be entitled to be paid the value of his stock on the date of the recording of the certificate, exclusive of any element of value arising from the expectation or accomplishment of the merger, all as provided in said Section 253(e).

Currently the number of publicly held shares of UEC fails to meet the New York Stock Exchange criterion for continued listing. The Exchange has informed UEC that October 24, 1966 has been tentatively set as the date when trading in UEC stock on the Exchange will be suspended.

Business and Operations of The United Electric Coal Companies

UEC is engaged in the production and sale of bituminous coal which is marketed in the Chicago, St. Louis and other Midwestern industrial areas.

The following summary of earnings of UEC for the years 1961 through 1965 has been prepared from the financial information contained in UEC's 1965 Annual Report to Stockholders. The information set forth for the nine-month periods ended September 30, 1965 and 1966, has not been audited, but in the opinion of UEC's management presents fairly the results of operations for such periods. Reference is made to the balance sheet of UEC at December 31, 1965, which was included in the 1965 Annual Report, and the unaudited balance sheet at September 30, 1966, and related notes, all of which are appended hereto. Copies of such 1965 Annual Report will be sent upon request.

GOVERNMENT EXHIBIT
Nug. Dep.
35 c

In 1965 UEC produced and sold 5,409,815 tons of bituminous coal compared with 5,801,52[illegible] in 1964. Production during the first nine months of 1966 exceeded production for the comp[illegible] period in 1965 by 516,663 tons.

Earnings for 1965 declined from the prior year as a result of extraordinary expenses incurred in connection with closing the Mary Moore Mine (where the coal reserves were exhausted), moving heavy equipment to other operating properties and, at two of UEC's four other mines, developing new operating pits and moving from worked-out areas. In addition, in the Spring of 1965 record flood conditions on the Mississippi River curtailed sales and disrupted operations for approximately two months at one of UEC's principal mines. For the first nine months of 1966, however, net income was $2,493,986 compared to $1,524,908 for the first nine months of 1965.

In 1964 and 1965 UEC sold 73% of its production to electric utilities, 23% to industrial users and 4% to others, with two electric utilities accounting for approximately 38% of total sales. Approximately 63% of sales in 1965 were made under term contracts (almost all with electric utilities) which will expire at various dates from December 31, 1966 to December 31, 1970, and an additional 9% of 1965 sales were made under term contracts expiring on or before December 31, 1974. Substantially all sales to industrial users are under one-year contracts or on a spot basis except for two contracts, one for 275,000 tons per year expiring on May 31, 1970 and the other for 325,000 tons per year expiring on December 31, 1968.

UEC competes intensively with other coal producers. In addition, atomic energy is becoming a competitive source of energy for electric utilities, but no prediction is made herein as to the long-range effect which atomic energy will have on coal utilization in the Midwest. General Dynamics is actively engaged in commercial development of atomic energy.

During the period from January 1960 to September 1966, the average price of bituminous coal sold by UEC declined from $4.27 to $4.10 per ton, with sales to electric utilities being made at slightly lower prices than to industrial users; substantially all of this reduction, however, has been offset by operating efficiencies and lower freight rates.

UEC operates four open pit or strip mines located in Illinois as follows: Fidelity Mine in Perry County, whose output is transported to market by rail and barge; Cuba Mine in Fulton County, which is strategically located to serve the Peoria market; and Buckheart Mine in Fulton County and Banner Mine in Fulton and Peoria Counties, which also serve the Peoria market and in addition are located close to the Illinois River, making possible low-cost transportation to the Chicago area. In addition, UEC has underground coal deposits in Illinois and strip coal and underground deposits near Hayden, in Routt County, Colorado.

UEC states that at December 31, 1965, it had approximately 84,600,000 tons of coal reserves in Illinois suitable for strip mining. Of this total, approximately 72,100,000 tons are dedicated to UEC's four existing mines which, at UEC's 1965 annual rate of production, have remaining lives ranging from 8 to 16 years. UEC also had approximately 50,800,000 tons of underground coal deposits in Illinois, and other miscellaneous reserves of 7,000,000 tons, but has no present plans to mine such coal.

In light of the limited life of UEC's existing strip mining reserves in Illinois and the unavailability of additional strip mining reserves in the Midwest, UEC has been engaged in an exploration program in Colorado and other western states to secure strip mining coal reserves which can be developed by utilizing UEC's strip mining machinery and equipment. As a result of such exploration program, in addition to the reserves described above UEC states that it has acquired in Colorado an estimated 12,500,000 tons of coal reserves suitable for strip mining, and an undetermined amount of underground coal reserves the extent of which has not been explored. UEC has no coal operations in Colorado and has no plans to commence operations there until increased demand for coal in that area makes development of such

GOVERNMENT EXHIBIT Rue 35 Dep.

reserves commercially feasible. Accordingly the future commercial success of the exploration program and the development of the Colorado reserves is a matter of speculation.

Approximately half of UEC's strip coal deposits and substantially all its underground coal deposits are leased; the balance of such reserves is owned in fee. At December 31, 1965, UEC had commitments of approximately $1,900,000 for advance royalty payments on long-term leases and $600,000 for future payments on contracts to purchase coal lands; approximately $630,000 of the total commitments of $2,500,000 was payable in 1966. At September 30, 1966, such commitments amounted to approximately $1,600,000 for advance royalty payments and $600,000 for future payments on contracts to purchase coal lands.

From time to time UEC has transactions in the ordinary course of business with Freeman Coal Mining Corporation, a wholly owned subsidiary of General Dynamics. In 1965 UEC sold approximately $1,284,000 of coal through Freeman Coal and Freeman Coal sold approximately $200,000 of coal through UEC. All such transactions have been on customary trade terms. In addition, UEC and Freeman Coal are supplying coal on a joint basis to certain customers.

UEC delivers a portion of its coal production by barge utilizing the facilities of three companies which are 50% owned by UEC.

A 30-month agreement with the United Mine Workers of America was reached in the Spring of 1966. Although the agreement will result in increased labor costs, UEC's term sales contracts contain escalation clauses so that the increased labor costs are not expected to have any material adverse effect upon UEC's earnings.

As set forth in its balance sheet as at September 30, 1966, UEC has issued 577,920 shares of Common Stock, of which 4,000 shares are held in treasury. Each share of Common Stock has the same rights and privileges; is entitled to one vote; participates equally in any dividends declared upon the Common Stock; and would participate equally in assets available for distribution to stockholders upon any liquidation, dissolution or winding-up. The Common Stock has no conversion or preemptive rights. The Transfer Agent for the Common Stock is The Chase Manhattan Bank (National Association).

Dividends have been paid on UEC Common Stock at the annual rate of $1.60 in 1961, $1.65 in 1962 and thereafter at the annual rate of $1.80. In connection with its guaranty of the obligations of certain affiliates, UEC has agreed to maintain working capital of $1,750,000 (at September 30, 1966, working capital was $11,134,822).

The following table sets forth the market prices of the Common Stock of UEC on the New York Stock Exchange:

Year or Period Ending	High	Low
1961	67½	44½
1962	64	41¾
1963	59	45¾
1964	55	44¾
1965	50¾	42¼
1966 (to September 30)	49¾	39½

On September 30, 1966, 100 shares of UEC Common Stock were traded on the New York Stock Exchange at $41¾ per share prior to the announcement of this tender offer. The last previous sale on the Exchange had taken place on September 22, 1966, when the closing price was $42¾.

GOVERNMENT EXHIBIT Misc. Exp. 35 a

General

General Dynamics may withdraw this Invitation, at its option, at any time during the initial or extended tender period, if a state of war has been declared by the United States, or if any banking moratorium or general suspension of trading on the New York Stock Exchange has been declared or if any legal action or proceeding shall have been instituted or threatened in any court or government agency against General Dynamics or UEC with regard to this tender offer.

General Dynamics makes no recommendation that stockholders of UEC tender or refrain from tendering all or any of their shares, and no one has been authorized to make any such recommendation. Each stockholder must make his own decision as to whether to tender shares and, if so, how many shares to tender.

Additional copies of this Invitation for Tenders and the Form of Tender and Assignment and UEC's Annual Report for 1965 can be obtained from The Chase Manhattan Bank (National Association), or at the following offices of Georgeson & Co.:

THE UNITED ELECTRIC COAL COMPANIES

BALANCE SHEET

December 31, 1965 and September 30, 1966

LIABILITIES

	December 31, 1965	September 30, 1966 (Unaudited)
Current Liabilities:		
Accounts payable and accrued expenses	$ 1,029,473	$ 781,012
Accrued salaries and wages, etc.	487,698	483,397
Federal income taxes	554,225	805,990
Dividend payable	—	303,264
Total current liabilities	2,071,396	2,373,663
Stockholders' Equity:		
Common stock—authorized, 750,000 shares of $5 par value each; issued, 677,920 shares (including 306,000 shares at previous aggregate stated value of $4,657,318)	6,516,918	6,516,918
Capital surplus	1,359,691	1,359,691
Earned surplus	21,619,625	22,900,555
	29,496,234	30,777,164
Deduct—cost of 4,000 common shares held in treasury	94,225	94,225
	29,402,009	30,682,939
Total	$31,473,405	$33,056,602

Notes:

1. Investments: Included in investments is the cost, $750,000, of the Company's investment in capital stocks of affiliates engaged in barge operations. The Company's equity in the combined net assets of these affiliates exceeds its investments therein. These barge affiliates had loans of $2,043,405 at December 31, 1965, and $2,360,886 at September 30, 1966, and the owners of these affiliates in effect guarantee that the revenues will be sufficient to repay the installments of these loans. In connection with such guarantee, the Company has also agreed to maintain working capital of $1,750,000.

2. Commitments: At December 31, 1965, the Company had commitments of approximately $1,300,000 for advance royalty payments on long-term coal leases and $600,000 for future payments on option contracts to purchase coal lands, of which approximately $630,000 is payable in the year ending December 31, 1966. At September 30, 1966, such commitments amounted to approximately $1,050,000 for advance royalty payments and $600,000 for future payments on contracts to purchase coal lands.

December 11, 1964

Mr. Frank Nugent, President
Freeman Coal Mining Corporation
300 W. Washington St.
Chicago, Illinois 60606

Dear Frank:

Enclosed please find four copies of the tabulation you requested of the Midwestern coal consumption by utility plants for the year 1963.

We trust that this is the information you wanted and if there is anything further we can do in this connection, please advise.

Best regards,

/s/ T. J. Tarzy
T. J. TARZY

NUG. DEP. EXHIBIT 49

BOARD OF DIRECTORS MEETING HELD OCTOBER 28, 1960

* * * *

Upon motion duly made by Mr. Nugent, and duly seconded by Mr. Falkoff, it was unanimously

RESOLVED, that the proper officers of this Company, for and on its behalf, be and they hereby are authorized and directed to place a purchase order for a 70 cubic yard stripping shovel costing approximately $2,800,000.00; and

FURTHER RESOLVED, that said order be subject to cancellation within 30 days from this date by payment of such expenditures as the manufacturer may have made during that time and which cannot be recouped by him.

The Chairman stated because of conversations in the past in regard to possible consolidation with another coal company in this area it might be well to give some consideration to the subject.

Thereupon, on motion duly made by Mr. Gebhart, and duly seconded by Mr. Thorson, Messrs. Nugent, Falkoff and Morris not voting, it was

RESOLVED, that a committee composed of Messrs. Nugent as Chairman, Falkoff and Morris be and they hereby are appointed to serve at the pleasure of this Board to investigate and report to this Board concerning such consolidation.

NUGENT EXHIBIT A

THE UNITED ELECTRIC COAL COMPANIES
307 North Michigan Avenue
Chicago 1, Illinois
FRANK F. KOLE
PRESIDENT

October 9, 1956

Mr. Henry Crown
Chairman of the Board
Material Service Corporation
300 West Washington Street
Chicago 6, Illinois

Dear Henry:

Herewith a comparison of ourselves and Traux-Traer based primarily on tons produced in each locality per annum showing what we would get in a merger and what we might be giving. The earnings by United and Truax per ton from the coal in each area should be the same over a period of time, as the overburden in each area is about the same on the average. Some years overburden will be much lower at one mine than another, resulting in lower stripping cost and lower blasting cost, but it will average out.

At present in Fulton County we are producing the same tons as Truax, but our potential reserves are 60 per cent greater, and ultimately this will be represented in production and sales. We are now building a new, larger wheel at our Cuba mine which will increase our capacity there 500,000 tons a year, and we are also considering the acquisition of a mine in the Banner area on the Illinois River just below Peoria. This mine is now producing 200,000 tons a year, and we might increase this to 700,000 tons. If we did this, our total capacity in Fulton County would be 3,300,000 tons, as compared with Truax's present 2,100,000. In Southern Illinois

Truax has much larger reserves than we do, but I do not think this is a particularly good place to have reserves. Our Danville and Buffalo Creek mines are very profitable mines, as profitable as or more profitable than similar mines in Fulton County. The Truax mines in West Virginia and in North Dakota are out of our territory, and I do not know anything about them.

More of the benefits would come from the Truax properties than from our own. At present the tonnage from the Little Sister properties goes to the Little Sister washer and then goes by Burlington Railroad to the Truax dock. We would take this to Buckheart and then down our railroad. At the Shakerag mine of Truax, the combined company might save money by putting in a washer to prepare only two sizes of coal, 2 x 4 and 2 x 0. The various other sizes could be produced at the Fidelity washer. This would make for a cheap and economical-to-run washer at the Shakerag properties.

For a consolidated company, the West Virginia tonnage does not have as much purpose as in the present Truax company, as in a consolidated company it would be only a fifth of the total output, instead of a third, and if certain expansion that we are contemplating were put through, it would be only a sixth. Under these circumstances, it would be only the tail of the dog, with its own mining and selling problems that would be completely different from the problems of the other 80 per cent. I doubt whether under these circumstances it would get the same progressive, forward-looking attention that the other 80 per cent would, and whatever it did get might detract from the attention that should be given to the properties in the Middle West. With the present move toward consolidations in the East and toward acquisition of properties, it might be that this property could be sold and the funds distributed to the present Truax stockholders, or they might be given preferred stock.

If the Eastern properties were taken out, our relative productions would be as follows:

	United's Production	Truax's Production	Excess of Truax's Production Over United's
Fulton County	2,100,000	2,100,000	—
Railroad—Profits in Tons of Coal Equivalent	300,000	—	(300,000)
Danville	300,000	—	(300,000)
Buffalo Creek	300,000	—	(300,000)
Total	3,000,000	2,100,000	(900,000)
Southern Illinois	1,500,000	2,500,000	1,000,000
Total	4,500,000	4,600,000	100,000
North Dakota	—	1,500,000	1,500,000
Total	4,500,000	6,100,000	1,600,000

The earnings from the 6,100,000 would not be far different from the earnings from the 4,500,000.

We are in a position now to go ahead with some expansion, and if we did so, we would be sharing the benefits of this with Truax. On the other hand, they would be paying their share of it. We have the possibility now of earning $3.50 or $4.00 a share from our present properties and of opening new mines which would increase these earnings. I just want to be sure that in a merger our earnings per share per annum would be increased.

Very sincerely yours,

/s/ Frank F. Kolbe
FRANK F. KOLBE
President

Profit before Income Taxes	4,144,000	21.1	2,704,500	15.3
Net Income	2,839,000	14.5	1,966,500	11.1

SALES

Sales were up because of more business and higher realization than anticipated in the budget.

PROFIT

Profit was greater because of higher sales as per above, and costs incurred have generally been lower than anticipated.

Included in net income is $13,420.06 of investment credit.

BALANCE SHEET

The Company had commitments of approximately $2,500,000 for payments of advance royalties and on option contracts to purchase coal lands.

Barge affiliates of the Company had loans of $2,568,606 as of September 30, 1966, and the owners of those affiliates in effect guarantee that the revenues will be sufficient to repay the installments of these loans.

As of October 31, 1966, the Company had a reserve for doubtful accounts of $50,000.

Included in cash as of October 31, 1966, are $5,475,000 of Certificates of Deposit.

Included in intercompany receivables are promissory notes in the amount of $2,000,000 from General Dynamics Corporation and accrued interest thereon of $6,333.

Gentlemen:

Re: United States v. General Dynamics Corporation et al., Civil Action No. 67 C 1632 (N. D. Ill.)

In response to your letter of April 15, we have accumulated the following data for you. Annual coal purchases in each of the years 1964 through 1967 in total tons and dollar value are as follows:

	Truax-Traer	United Electric	Republic	Peabody
1964				
Tonnage	80901	47529	23081	6972
$ Value	$353,993.72	$201,638.35	$132,801.62	$31,219.16
1965				
Tonnage	81337	46512	29430	6885
$ Value	362,567.90	207,523.61	134,250.11	30,972.57
1966				
Tonnage	76316	44371	20703	7534
$ Value	343,079.74	204,316.73	199,816.60	40,144.04
1967				
Tonnage	79392	52169	28396	13338
$ Value	349,105.92	245,725.43	130,490.98	58,007.23

Some of the above suppliers maintain more than one mine, and their billing does not reflect from which of these mines the shipment originated. All of the mines supplying our plant are located within a 25 mile radius of

scheduled
5-22-68

DEPARTMENT OF JUSTICE
MAY 2 1968
CIVIL DIVISION

Peoria. The type of coal we use, namely No. 5 and No. 6 Seam, precludes shipment from any other area.

Coal is purchased by our Peoria facility as a fuel to generate steam for our Power Plant. We purchase stoker screening type coal; it is used by equipment described as follows: 1 Erie City boiler with a Detroit stoker; 3 Combustion Engineering with Combustion stokers. Three stokers are overthrow spreader type and one is an underthrow spreader design. We are equipped to burn gas or oil, however coal is used as a more efficient, economical, fuel.

Our Peoria plant does not consume any other energy fuel for the same purpose for which coal is required.

We do consume other types of energy fuel such as gas and fuel oil for our Open Hearth furnaces, for many reheating furnaces, and for heat treating devices throughout our plant. Coal could not be used as a substitute for any of these purposes. A 60% - 40% gas-oil mixture is used in our Open Hearth furnaces. This mixture produces the most efficient, desirable flame for melt-down purposes. In all other locations we consume gas; it is the most efficient fuel available in each instance. We are equipped to substitute oil in each of these locations during the winter months when the local utility interrupts our service because of severe weather conditions.

We have no charts, surveys, or memoranda to substantiate the above information; however, any of the facts stated above may be verified by our technicians or by a visit to our plant. We have indicated our reasons for not converting to other fuel sources.

We hope this information will materially assist you.

Very truly yours,

R. A. Redard

R. A. REDARD

AN EVALUATION OF ILLINOIS COAL RESERVE ESTIMATES

J. A. SIMON, *Principal Geologist* and W. H. SMITH, *Geologist*
Illinois State Geological Survey
Urbana, Illinois 61801

INTRODUCTION

Illinois has the largest total bituminous coal reserves and the largest strippable bituminous coal reserves of any state in the Union (figs. 1 and 2). A large percentage of these reserves are characterized as relatively thick and flat-lying coal seams. The coal-bearing sequence of rocks underlies about two-thirds (36,806 square miles) of the state and includes more than 50 coal seams, about 20 of which have been commercially mined at least locally. Most production has come from six to eight coal seams, and 85 to 90 percent of the total production has come from the Herrin (No. 6) and Harrisburg-Springfield (No. 5) Coals.

This report has two primary purposes: (1) to review the status of coal reserve estimates for Illinois, including those for both total reserves and strippable reserves and (2) to offer some comments on the significance and meaning of coal reserve estimates.

It is not necessary here to define most of the terms that will be used in this report. A few, however,—coal resources, coal reserves, minable coal reserves, and strippable coal reserves—are frequently used interchangeably even though they are not synonymous, and their common usage and use in this report should be clearly understood.

Coal resources are all coal that occurs in the ground in any designated area without regard to thickness or minability. The only limitation is that the material being considered meets a suitable definition of coal. In this report, we are not concerned directly with coal resources except to note that coal resources in Illinois are much larger than coal reserves, as defined below, and that quantities of coal resources not now classified as reserves will be so classified in the future.

Coal reserves are that portion of coal resources, usually measured in tons, that are commonly limited by minimum thickness, often by maximum depth, and occasionally by other factors.

Minable coal reserves normally are coal reserves that can be re-

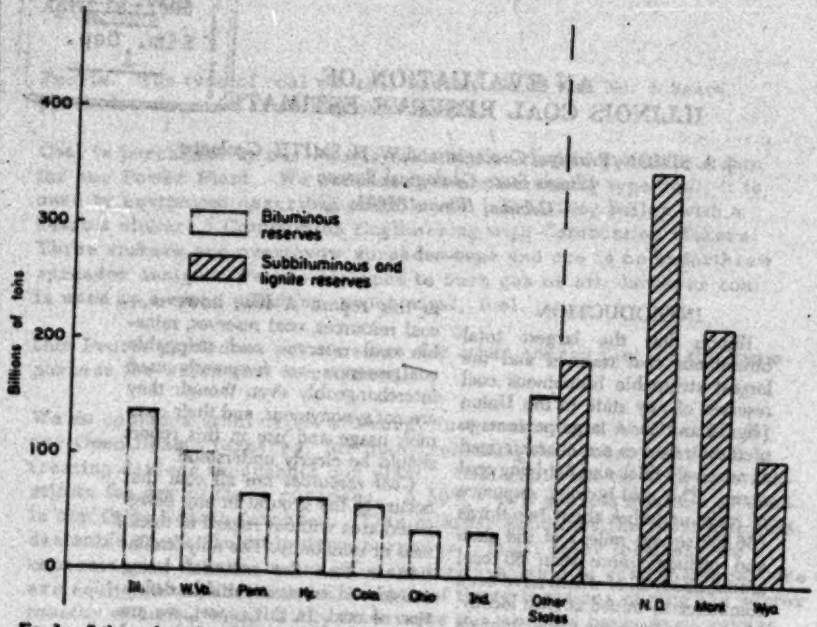

Fig. 1 — Estimated total remaining coal reserves of the United States, Jan. 1, 1967. Data from Paul Averitt, U. S. Geological Survey, personal communication, 1968.

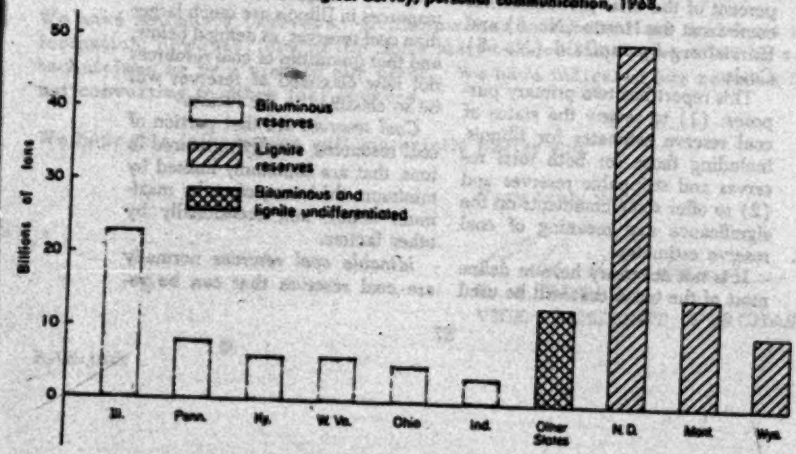

Fig. 2 — Estimated original reserves of strippable coal in the United States. Data from Averitt (1960, 1968).

covered by existing techniques, but most published studies have specifically considered neither technology nor the economics of mining, which are often merely implied in determining reserves. Generally, so-called minable coal reserves determinations have been based solely on presence of coal of a predetermined minimum or greater thickness and (in some cases) a maximum depth. Thus as generally reported, the terms *coal reserves* and *minable coal reserves* are synonymous, or nearly so. The desirability of distinguishing between *coal reserves* and technologically and economically *minable coal reserves* is obvious, but the fact that this differentiation has not generally been made in regional reserves studies should be well understood.

Strippable coal reserves carries the same implications of technologic and economic producibility as *minable coal reserves*, but in common practice they have been defined only by minimum thickness and either depth of overburden or stripping ratio for large areas ranging in size from counties up to a whole state.

Certain information is needed in studies of coal reserves of a large area. Some of the data are usually included in reserves studies, but other data are generally ignored. This report discusses both. The data usually given in reports include the following (as defined in each study):

a) Estimate of total coal in the ground by seam
b) Area where reserves were estimated
c) Degree of reliability of the estimates
d) Thickness categories for the estimates down to a minimum thickness considered
e) Thickness of overburden, or stripping ratio, for strip coal

Not included in most such studies are:

a) Quality (except broad rank categories)
b) Depth
c) Mining conditions
d) Economics
e) Land availability
f) Regulations and controls

COAL RESERVES OF ILLINOIS

The great need for coal reserves data in the United States was widely recognized after the turn of this century. In 1908, F. W. DeWolf, then Assistant State Geologist of Illinois, estimated about 137 billion tons of original coal reserves for Illinois.

Since that first state-wide summary of reserves, several additional authoritative estimates have been made (table 1). All but one exceeded DeWolf's estimate. The lowest estimate shown in table 1 included a number of factors not considered in any of the other estimates and generally excluded large areas where very little reliable data existed.

A series of detailed studies, including reserves estimates, was made for the various mining districts of the state by several authors

TABLE 1 – PRINCIPAL ESTIMATES OF ILLINOIS COAL RESERVES

Source	Date	Billions of tons in the ground	Minimum Thickness (in.)

Averitt and Berryhill	1950	165.6	?
*Ford, Bacon, and Davis	1951	49.6	28 (underground) 12 (strippable)
Cady	1952	137.3	28
Simon and Smith	1968	140.0	28 (underground) 18 (strippable)

*Minability factors considered in addition to presence of coal.

between 1915 and 1925. These were published as a series of Cooperative Mining Investigations Bulletins (see Illinois Geological Survey List of Publications). G. H. Cady (1946), in an unpublished manuscript, tabulated the reserve estimates from these earlier studies, modified the totals where appropriate, and added additional information not included in the earlier studies. This compilation was the basis for the reserves data published by Averitt and Berryhill (1950).

In the early 1950's the Illinois State Geological Survey undertook another study of coal reserves of the state. This report (Cady et al., 1952) is the most comprehensive study yet made for Illinois. It utilized a very extensive file of drill hole logs and mine notes that the Survey had accumulated over a period of nearly 50 years. Cady's report has been the basis for most later coal reserves estimates for Illinois, such as that of Averitt (1960). It is interesting to note that the total remaining reserves in the 1952 study were nearly identical to the rough original reserves estimates DeWolf made many years earlier.

During the past 12 years, a series of detailed studies estimating strippable coal reserves (defined in the reports) has been made in Illinois. Most of the potential areas of strippable reserves in Illinois have now been studied. Seven parts of the nine-part series have been published (Smith 1957, 1958, 1961, 1968, Smith and Berggren, 1963, Reinertsen, 1964, Searight and Smith, in preparation). Two unmapped areas are currently being examined to complete the series.

Data collected in the strippable coal reserves studies and detailed reports on several counties published since the Cady report have resulted in modification of the esti-

mated remaining reserves. The remaining total coal reserves are estimated to be 140 billion tons (fig. 3). This amount, as defined in Cady's report and the strippable studies, was arrived at by reducing Cady's 1952 estimate by production since 1952 plus an equal amount of coal rendered unminable by such mining, and then adding reserves mapped in later studies. These reserves, classified by principal seam, are shown in figure 4.

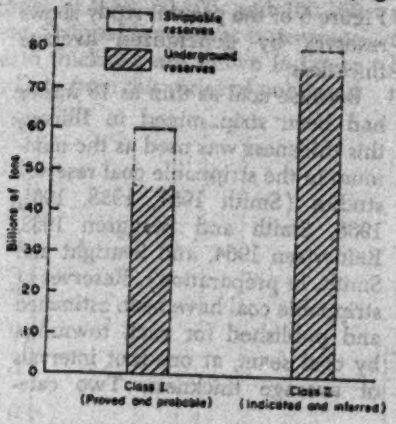

Fig. 3—Coal reserves of Illinois, 1968 (140 billion tons). Data from Cady et al. (1952), Smith (1957, 1958, 1961, 1968), Smith and Berggren (1963), Reinertsen (1964), and Searight and Smith in preparation).

We regard this estimate, *as it has been defined*, to be conservative. We are confident that continuing studies of Illinois coal resources will discover further reserves at a more rapid rate than the coal will be removed by mining or rendered unminable by mining for a number of years in the future. Large areas remain where coal-bearing strata are relatively untested, and there are areas where reserves data have been assembled on only the better

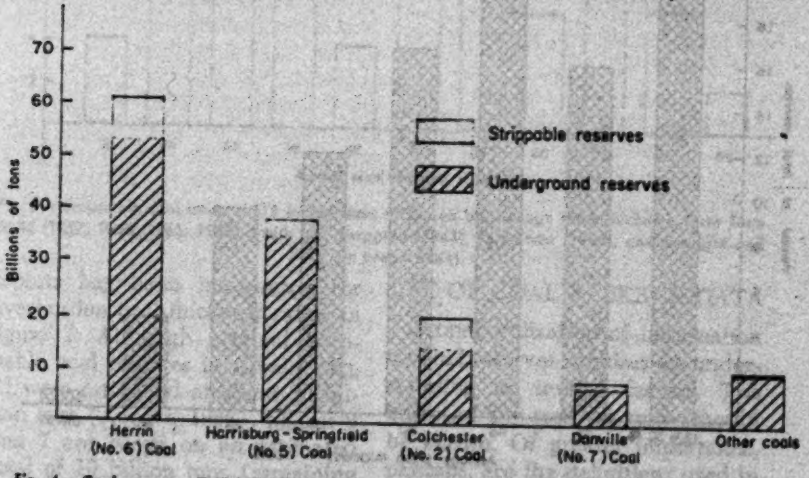

Fig. 4—Coal reserves (140 billion tons) of Illinois by coal seam. Data from Cady et al. (1952), Smith (1957, 1958, 1961, 1968), Smith and Berggren (1963), Reinertsen (1964), and Searight and Smith (in preparation).

known No. 6 and No. 5 Coals, although these are underlain by from several hundred to more than 1000 feet of coal-bearing strata in which coal thickness is not well known.

The Cady (1952) report on minable coal reserves of Illinois defined minable coal as being 28 inches or more thick. Most of the coal considered in the study was at depths of less than 1000 feet and none exceeded 1300 feet; no classification by depth was made.

Four classes of reliability, based on the quality of data used, were established and reserves computed for each coal seam at 1-foot intervals of avarage thickness. The published data were grouped by county, although calculations also had been made for each township. Figure 5 of the present study shows reserves by generalized average thickness.

Because coal as thin as 18 inches had been strip mined in Illinois, this thickness was used as the minimum in the strippable coal reserves studies (Smith 1957, 1958, 1961, 1968, Smith and Berggren 1963, Reinertsen 1964, and Searight and Smith, in preparation). Reserves of strippable coal have been estimated and published for each township, by coal seam, at one-foot intervals of average thickness. Two cate-

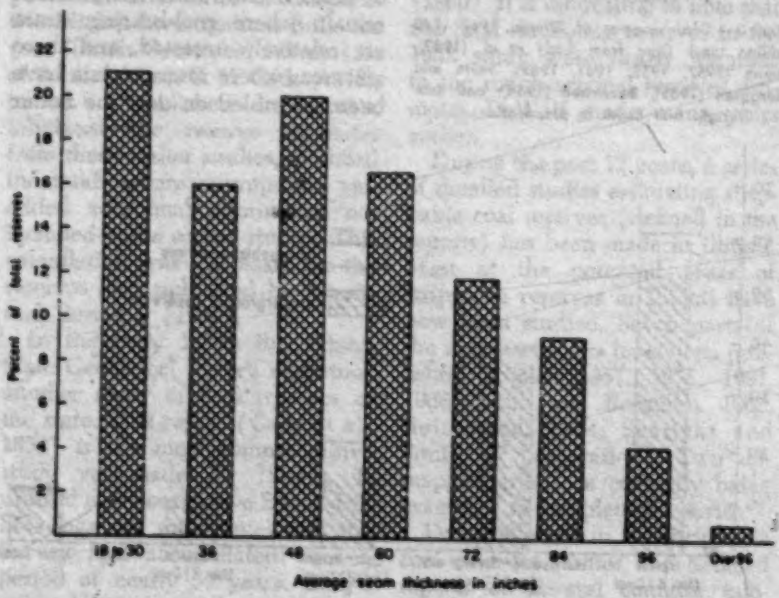

Fig. 5—Total coal reserves (140 billion tons) of Illinois by average seam thickness. Data from Cady et al. (1952), Smith (1957, 1958, 1961, 1968), Smith and Berggren (1963), Reinertsen (1964), and Searight and Smith (in preparation).

gories of reliability, based on the quality of the data, have been used. Overburden was divided into categories of 0-50, 50-100, and 100-150 feet. Strippable reserves by average seam thickness are shown in figure 6. Data from this series of published reports has been interpreted for overburden coal-thickness ratios in figure 7. Although original strippable coal reserves in Illinois (fig. 2) were estimated at about 23 billion tons (Averitt, 1968), figures 6 and 7 are based on an estimated total of 19 billion tons (remaining in the ground) only for the areas for which the reports on strippable coal reserves are completed. The original reserve figure cited by Averitt includes coal that has been mined and a preliminary estimate of reserves in the two areas yet to be mapped for the strippable coal reserves series.

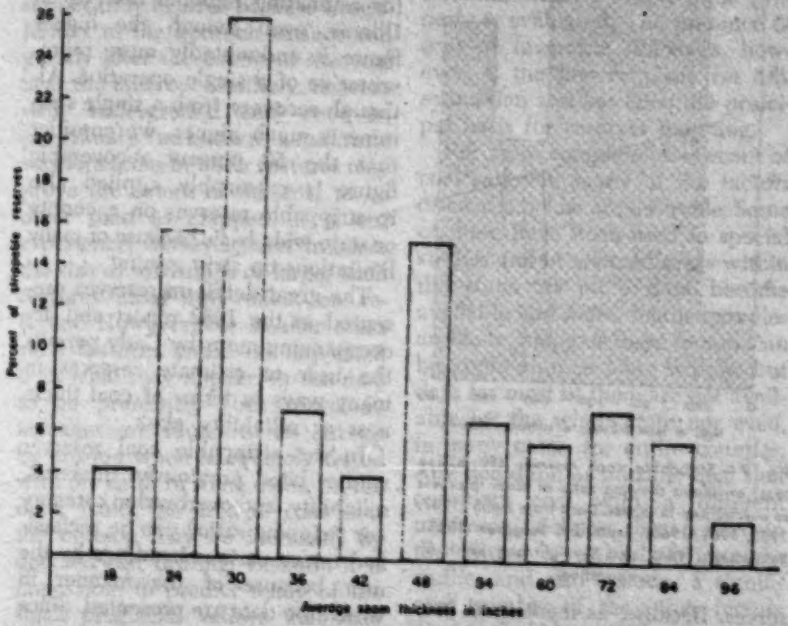

Fig. 6 — Strippable coal reserves (19 billion tons) of Illinois by average seam thickness. Data from Smith (1957, 1958, 1961, 1968), Smith and Berggren (1963), Reinertsen (1964), and Searight and Smith (in preparation).

USE OF COAL RESERVE DATA

Proper utilization of information on coal reserves requires an understanding of several factors. The object of any reserves study should be known. Of greater importance, perhaps, are the definitions used in each study, particularly terms such as "minable" or "strippable" re-

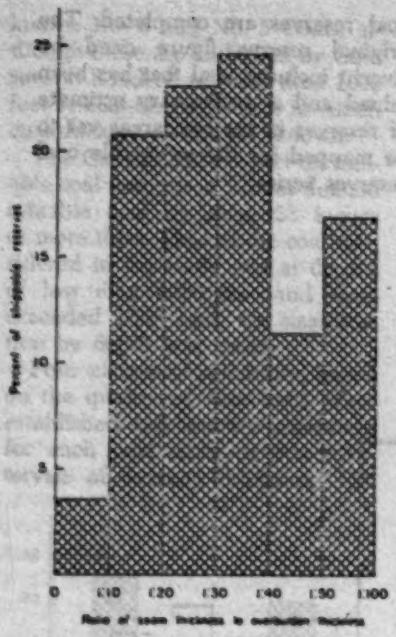

Fig. 7—Strippable coal reserves (19 billion tons) of Illinois showing ratio of seam thickness to overburden thickness. Data from Smith (1957, 1958, 1961, 1968), Smith and Berggren (1963), Reinertsen (1964), and Seeright and Smith (in preparation).

serves. Because, as mentioned previously, economics and technology are not fully considered in most studies of reserves, consideration of "minable reserves" must take this fact into account.

Distinction should be made between total coal in the ground and "recoverable" coal. Long-term general practice has indicated that 50 percent is a reasonable estimate of the amount of minable coal reserves recoverable. A recent study by Lawrie (1968) reported 57 percent of coal recoverable in modern underground mines. Considering losses of coal left between mines, surface culture that will not permit mining, and other factors making the coal unavailable, we regard 50 percent as a better recovery figure for estimating regional reserves in Illinois, even though the higher figure is undoubtedly more representative of a single operation. Although recovery from a single strip mine is much higher, we consider that the 50 percent recoverable figure is reasonably applied also to strippable reserves on a county or state-wide basis because of many limitations on strip mining.

The great detail on reserves presented in the 1952 report and accompanying maps by Cady permits the user to estimate reserves in many ways in terms of coal thickness or reliability class.

In the strippable coal reserves studies cited previously, thickness, reliability, and overburden category (or stripping ratio) can be reclassified under various headings by the user because of the manner in which the data are presented. Since thickness of reserves are generally reported at 6-inch to 1-foot intervals of average thickness, any minimum thickness greater than the 18-inch minimum used in these studies can be selected and any overburden limit can be assumed. Strip mine overburden limits are indicated on maps at 50, 100, and 150 feet, but estimates for intervening intervals can be made reasonably accurately.

The coal reserves data published

for Illinois has been misused in some cases. It is not always recognized that many areas of the state have been mapped from inadequate data. In such areas details on relatively small acreages, particularly in the case of strip coal, may be significantly in error because irregularities in the bedrock surface can greatly alter the extent of the coal near the outcrop. Similarly, in areas with underground coal reserves, previously unknown sandstone washout areas or other features may prove the extent of the coal to be other than as mapped. It is our experience, however, that in areas the size of townships or larger such features have little effect on reserves. However, for smaller areas such features could be important if in what may appear on the map to be promising (but untested) acreages are found to be cut up by erosion when adequately tested with the drill. In some cases, on the other hand, the area of coal near the outcrop may be increased by detailed test drilling. Because it is impossible to predict many of the small preglacial valleys that may reduce the coal mapped as available, we feel that there will generally be more reduction than increase of the shallow reserves with less than 50 feet of overburden. Again, however, we emphasize that this does not significantly reduce over-all reserves estimates as defined in recent studies published by the Geological Survey, even though tracts of up to several hundred acres may be found to be adversely affected when tested in detail.

OTHER FACTORS NEEDED FOR COAL RESERVES EVALUATION

Reserves estimates of coal in the ground in large areas have not included all of the data that are essential when a single mine property is evaluated. The presence of coal of favorable thickness, however, is the first requisite for any evaluation and has been the principal basis for reserves mapping.

For more complete assessment of coal reserves, many of the factors discussed below are desirable. Some of these have been used in special studies and in selected areas within the state. As more data become available and more detailed studies are done, many of these factors can be applied much more widely, but data for most of them are not available for the whole state nor even, in many cases, for entire counties. Any definition of minable coal that considers coal with a different minimum thickness than is used in the Survey's published reserves studies and also includes a significant number of the other factors discussed below will, of course, produce total reserve figures different from those reported in recent reserves studies. This, however, does not change the reserve figures *as defined* in these studies.

Within the limits of this paper, little more than a listing is practical to indicate the many other factors desirable for assessing coal reserves. Although such information is reliable now for only small areas, sufficient data may someday be

available to permit their use in state-wide evaluations.

Quality

Coal quality should be considered in evaluating reserves. Evaluation of quality may include rank, fixed carbon, volatile matter, heating value, moisture, ash, totals and varieties of sulfur, chloride-alkali content, petrographic composition, and coking characteristics. Rank, heating value, moisture, and chloride-alkali content show systematic variation so that at least some known reserves could be, or have been, mapped in terms of these factors.

Depth

Although sufficient data are available for mapping coal reserves by depth categories, this has not generally been done in Illinois, because most mapped reserves lie at depths of less than 1,000 feet and practically none of them are below about 1,300 feet. However, deeper coals are believed to occur, with thicknesses great enough to be considered reserves as defined in most previous studies, and a classification based on depth for coals (other than the strippable coal reserves that are now so classified) seem desirable. For Illinois, eventually a breakdown that would include coal reserves to a depth of 1,000 feet, 1,000 to 2,000 feet, and greater than 2,000 feet might be appropriate. It is unlikely that there is any coal deeper than 2,500 feet within the state.

Mining Conditions

The factors controlling mining conditions are perhaps the most significant determinant of the "minability" of coal reserves, but these are also among the most difficult to assess on a broad-area basis. They include the quality of the potential mine roof and floor strata, hardness of the coal, water conditions, mined-out areas in higher and/or lower coals, character of overburden, and a wide variety of geologic features that may profoundly affect mining, such as faults, cutouts, horsebacks, rolls, whitetop, and igneous intrusions. Only mined-out areas and many coal washout areas are sufficiently well known to have been used to modify reserves. Although the actual areas mined out have been excluded from recent estimates, no modification has been made for coals present above or below a mined-out area.

Economics

The economic effects of factors that influence the "minability" of coal are constantly changing. Among the more vital factors to be considered economically important are capital and mining costs, markets, and availability of transportation and its cost. Such factors not only vary with time, but for any given time may vary significantly in different parts of the state.

Land Availability

Although factors concerned with land availability are closely related to economic considerations, many

of their other aspects are important. They include the availability of a sufficiently large block of coal, land that can be acquired, exclusions resulting from towns, railroads, highways, and similar features, and oil field areas. Current reserves estimates have excluded all areas heavily drilled for oil and gas. It is quite probable that future technology may permit mining of such areas, which would then result in significant increase in reserves mapped to date.

Regulations and Controls

Evaluation of a potential mine site may involve several additional factors, most of which would be difficult to apply to an assessment of statewide coal reserves. They include controls on water supply, waste or refuse disposal, mining regulations, stream and air pollution, and reclamation requirements.

CONCLUSIONS

Published coal reserves data for broad areas may be a valuable guide in economic evaluation and planning. If used with full understanding of the premises on which the estimate is based, they can also be an aid to exploration. Total coal resources (all coal in the ground) in Illinois are considerably larger than estimates of reserves, and as more information becomes available, significant additional quantities of the coal resources of the state will be added to reserves, as reserves are defined in most existing reserves estimates. Although total coal reserve estimates of Illinois are considered to be conservative as defined in Survey studies to date, minable or strippable reserve estimates based on these data will be smaller if mining is restricted to thicker seams or the estimates are modified by definitions of economic minability. They would also be increased by including thinner seams.

There is not, and never has been on the national or state level, any intention to suggest that coal with a minimum thickness of 14, 18, 28, or more inches, is minable throughout the areas mapped, even though such thicknesses have been and are being mined in favorable situations. Data presented in recent studies for Illinois, however, provide the basis for estimates to be made within any of the defined thickness limits and for any defined overburden limits.

Illinois is in a most favorable position for a greatly expanded coal industry because of the quantity of its reserves, and its relatively thick and flat-lying seams. Other factors favorable for at least broad areas of the state that were mentioned but not discussed in detail in the report insure a bright future for the coal industry in Illinois. Much work remains to be done to assess minable coal reserves in terms of quality, mining conditions, economics, and other factors. Programs of the Illinois Geological Survey are being applied to fill this need where sufficient data are available.

Mr. R. J. Hepburn

January 21, 1963

Mr. Robert S. Overbeck, General Manager
Raw Materials Division
Aluminum Company of America
1501 Alcoa Building
Pittsburgh 19, Pennsylvania

Dear Mr. Overbeck:

Thank you for your letter of December 13, 1962 in which you answered the questions raised in my letter of November 29, 1962.

We appreciate the thoughtful consideration given to United Electric's position in respect to conducting the mining operation when Alcoa wishes to exploit the Beaucoup Field, as set out in paragraph (a) of your letter.

Also, we understand that should United Electric be confronted with a specific opportunity to furnish coal that could be supplied from Beaucoup Field, Alcoa is willing to consider seriously leasing part of Beaucoup Field to United for that purpose. This, as set out in paragraph (b) of your letter.

We agree with you that there were no commitments other than those spelled out in the written agreement and we accept your judgment as to the understanding stated in Paragraphs (a) and (b) in your letter.

In regard to the third point raised in my letter of November 29th our thought had been to explore the possibility of leasing from Alcoa the top tier of sections in Beaucoup Field, that is, from east to west Sections 14, 15, 16, 17, 18 and 13, and we appreciate your willingness to discuss the idea. As you probably know we have been leasing and optioning the coal immediately north of the sections listed above and now have some 23 million tons under control, a location we refer to as the Round Prairie Field.

Since my letter to you we have decided to expand our holdings in Round Prairie to a minable reserve rather than work out a leasing arrangement with Alcoa, in the meantime, however, trusting that leasing from Alcoa continues to be a possibility for future discussion.

Thanking you for your attention to these matters.

Sincerely,

Secretary

Employment:

1944-1946	USNR
1947-1949	Teaching Fellow in Economics, Harvard
1949-1957	Lecturer, Instructor, Assistant Professor, University of California, Berkeley
1957-1959	Associate Professor of Economics, University of Wisconsin
1959-1968	Professor of Economics, University of Wisconsin
1968-	Professor of Economics and Law, University of Michigan

Fellowships:

Social Science Research Council, Faculty Research Fellow, 1956-1959
Guggenheim Fellow, 1960-1961
Ford Faculty Research Fellow, 1965-1966

Ph.D. Thesis: *Workable Competition in Radio Broadcasting* (Harvard, 1949)

Publications:

Books:

Productivity (with William Goldner) (University of California, Berkeley, 1952).

An Introduction to the Analysis of Time Series (Rinehart & Co., New York, 1956).

STEINER DEPOSITION
EXHIBIT 2

U.S. v. General Dynamics, et al.

MEMORANDUM OF EXPECTED TESTIMONY
of
Peter O. Steiner
Professor of Economics and Law
University of Michigan

1. Coal mining today is in the midst of a period of change so rapid and so pervasive that it has required, and continues to require, major readjustments in the structure and patterns of coal production and distribution. This rapidly changing context compels a dynamic, rather than static, examination of the structure of coal mining and of the role and effectiveness of competition. To analyze or evaluate the structure and patterns of coal production and distribution out of this context of pervasive change in the conditions of both demand and supply invites the confusion of cause with effect, and overlooks the success of coal producers in providing the nation with the benefits of vigorous competition.

2. While coal mining has suffered many set-backs since its heyday of the 1920's, the changes since World War II have provided a major challenge. Importantly, the railroad market has totally disappeared, the space heating market has virtually disappeared and the industrial steam coal market has declined. Thus, increasingly, coal producers have had to look to the electric utilities as the major source of their demand, and to adapt themselves to new requirements in order to compete effectively.

The decline in the number of producing firms from 1957 to 1967 illustrates the working of economic evolution: viable organizations have survived and those that were not have disappeared. The period of rapid change and basic challange to individual coal producers, and coal mining as a whole, has not ended. The utilization of nuclear energy is playing a major role in the current expansion program of electric utilities, and can only increase in the decades ahead. The increasing concern with air pollution provides a related but further threat to coal producers. Meeting anti-pollution requirements is bound to adversely affect coal's ability to compete with other fuels. This will result from the increased costs of using lower sulphur coals or in providing effective anti-pollution devices for existing grades of coal.

3. Competition as a goal of public policy is designed to assure low prices, to assure prompt response by suppliers to changes in patterns of demand and to keep producers under continuous pressure to find new and better ways to satisfy consumers' wants. Lack of effective competition may frustrate each of these purposes and lead to higher prices, to unaggressive and unresponsive behavior and to a generally unprogressive industry. The appropriate test of the competitiveness of any industry is its performance in these respects. The record shows that coal production has adapted to the change in the pattern of demand thrust upon it, and has managed to

increase productivity enough so that despite rising unit labor costs, the delivered price of energy from coal has remained stable. That it has done so by major innovation in the production, preparation, loading and marketing of coal is testimony to the effectiveness of competition both among coal producers and between coal and other energy sources.

4. The data show that over this period the size of mines has increased, the size of coal companies has increased and the number of viable mining companies has decreased. These things are not, as the Government complains, the symptoms of a lessening of competition, but are instead adaptations by coal producers to changes imposed upon them by the changes in the demand for coal and competition in the energy market. The increasing predominance of the electrical utilities as purchasers of steam coal, the increase in the designed capacity of new electric generation units, and utilities' insistence on a large, reliable, and low price source of fuel over the 20 or 30 year life of a generating facility, lead inexorably to the emergence and survival of coal producers with large reserves, developing large mines which are devoted to serving a small number of customers on long term contracts. The pressure to achieve low transportation costs on a freight-intensive commodity has reinforced the need for the long term commitment that only a large company with substantial reserves can credibly contract to provide.

5. The progressive disappearance of the small producer reflects the disappearance of the railroad market and the decline of the space heating market, the retail market and spot coal purchases by utilities. The need to commit vast reserves of coal to each major contract has led to the disappearance of producers with small reserves as active competitors in the utility market and has led to the assembling of large blocks of coal reserves under single managements. Competition among coal producers is characteristically no longer the competition of salesmen for coal already produced, but is instead the competition for long term supply contracts. Typically, the opening of a mine is geared both to a given long term contract, a given plant location, and a previously negotiated freight rate. This gives a special quality to competition that manifestly is not of a kind in which a small producer or a producer without large reserves can effectively compete.

6. The competitive viability of a producing company in the utility market is today measured not by its current production, nor by its current profits or cash flow, but, instead, by its ability to compete in the market for new long term contracts. This requires availability of acceptable reserves and of low cost transportation, and sufficient credibility both to assure performance on a contract and to acquire the funds necessary for producing the coal. For the same

reasons, the comparative competitive strength among coal producers and their prospective market positions should be measured by the quantity, quality and location of their reserves, rather than by their current or past levels of production.

7. The growth of mine size and the share of production by large coal producers is a direct response to the intense competition for the utility business both between coal producers and among competing fuels. Substitutability between coal and some competing energy sources exists even with existing facilities. Many of these already have the capability for alternative fuel use, and others could readily acquire it. The fact that coal continues to supply so much of the energy requirements of the electrical utilities reflects the success of coal producers in delivering coal at a low cost per BTU. That it has done this, despite sharply rising costs, reflects the technological revolution that has led to enormous increases in productivity, and to the ability to negotiate bulk shipment and unit train freight rates. Both coal prices and coal rail rates have increased far less than other prices in the economy. But these innovations, which make competitive prices possible, have created the need for large scale production, and thus for large companies.

8. The longer run competition among fuels concerns the design and location of new facilities rather than the

utilization of existing facilities. The dramatic emergence of nuclear energy as a competitive force is shown in the record. Coal producers will in fact be under continuing pressure to reduce costs and keep prices low if they are to retain their last remaining large market for steam coal. Again, coal's relative disadvantage, vis-a-vis other fuels, with respect to air pollution regulations increases the pressure upon it. The large coal company has no easy life nor protected position.

9. Electric utilities typically regard fuel purchasing as a top executive responsibility and the buyers are characteristically sophisticated about the available alternatives. This is another source of pressure on coal producers to seek to minimize costs and to keep prices low. The large utilities purchase coal in quantities that give them substantial market power, preventing any excess of bargaining power on the part of the producers. Utilities have and use the ability to play coal producers against one another. Moreover, some utilities possess their own coal reserves which add to their bargaining strength. Finally, inter-fuel substitutability provides an additional bargaining advantage to utilities.

10. In the context of this litigation, anti-merger policy should seek to preserve a sufficient number of alternative sources of supply to customers to assure competitive

behavior. This requires that we identify the relevant customers and their sources of supply, and examine the roles of United Electric and Freeman therein. In my view, the only significant product market within which to evaluate the competitive effect of the UEC-Freeman case is the supply of energy for electricity generation. The broad geographic area in which the midwestern utilities purchase energy is in fact a series of different markets. Defining the precise boundaries within which a particular utility generating station can purchase fuel is a complex but manageable matter that depends on the transportation routes available, freight rates, and technical characteristics of the fuel. Not all coal producers in the State of Illinois can effectively bid on all coal contracts. While two mines producing coal will often have some area in which they may both ship at equal cost, each will have areas where it is in a position to exclude the other supplier.

11. In negotiating for new locations of electric generating stations there are often wide alternative sources of supply both among fuels, and among producers of a given fuel. Once a facility is located and its equipment designed to utilize particular fuels, the alternative sources of supply have been narrowed. But characteristically, most of its fuel requirements have already been assured by that time, through long term supply contracts with one, or at most a few, suppliers.

12. In my judgment, on the basis of the record to

date, the UEC-Freeman combination does not have the effect of reducing competition, nor would a divestiture increase competition, for several reasons. First, because of its lack of reserves of the necessary quantity, quality and location, UEC alone is no longer able to compete effectively for meaningful long term supply contracts. Its inability to acquire additional strip reserves and its lack of underground capability are well documented. Second, because a combined UEC-Freeman does not represent excessive market power. The combined operation faces vigorous competition from other large coal producers, it faces the ever present threat of displacement of coal by competing fuels and it faces large and sophisticated buyers across the bargaining table. Third, because of differences in the location of its mines, in the quality of its coals and in the nature of its transportation routes, Freeman and UEC have long been predominantly complementary rather than competitive producers. Many of the common customer shipments identified in the record reflect this complementarity. Where common customers have existed, there is in the main no shortage of bargaining power on the part of the purchasers such that they have been disadvantaged by the common ownership.

WEIR DEPOSITION EXHIBIT 8

August 5, 1959

Mr. R. J. Hepburn:

Re: #2 Coal South of Illinois River

In looking over our maps and those obtained from CILCO, there appears to be an area of coal south of the Illinois River located in Springfield Township, Tazewell County, Illinois.

As you know, this will have to be checked as CILCO drilling was intent on the lower geological structures. However, there appears a possibility of 8,000,000 tons with an average overburden of 35 feet in an area due south of Bessie Smith, Dempsey, and Sprague. The land is bottom land.

In going about getting drilling information, I have talked to Mr. J. M. Morris suggesting we use CILCO for obtaining drilling rights, etc. As you know, Mr. George Otto is a consulting geologist and is connected with them at this time. I feel this is the best way.

Any information we obtain by drilling for coal in this area would be valuable to CILCO as they have used in the past our coal drilling north of the river to an advantage.

R. H. INMAN

about our company and procedures

Established in 1936 by Paul Weir, the firm has enjoyed a record of continuous growth and expanding activity. Over the years, the Paul Weir Company has built a reputation, of which we are proud, for successful and dependable performance both within the North American continent and abroad. Our policies permit no deviation from the highest professional and engineering standards.

Because the Paul Weir Company does not manufacture, sell or distribute machinery or equipment, our recommendations are completely unbiased and impartial, assuring selection of procedures, methods and facilities best suited to any specific set of conditions.

Upon authorization for any assignment, whether large or small, the principal officers of the Paul Weir Company first analyze all aspects of the project, outline and supervise the necessary work, then prepare or review the eventual final report or recommendation. Additionally, throughout every project, any special problems arising in the various fields of geology, mining, engineering, beneficiation, utilization, construction, training, economics, management or operations are referred to the close scrutiny of those principals or staff experts highly qualified in the particular field involved.

When staffing teams in the field on projects abroad we place emphasis on the ability of our personnel to function without friction both within the company group and with the technical staff and residents of the host country. On major projects abroad we are prepared to establish fully integrated teams in the field with the ability and authority to execute the work and make necessary decisions on the spot, without the necessity of referring problems and decisions to the home office, except in unusual circumstances. The home office at all times, however, continues to provide field teams with back-up information, support and advice as required.

With the experience derived from many years of specialized consulting services as well as that embodied in the combined professional background of the principal staff, the Paul Weir Company has compiled a comprehensive library of technical publications, authoritative information and data. This material is available to all staff members and provides supplementary aids and expedient suggestions for solution of new project problems.

SERVICES

The Paul Weir Company offers a complete range of consulting and engineering services on a world-wide basis to owners, producers and users of coal, other solid fuels, and mineral resources in general.

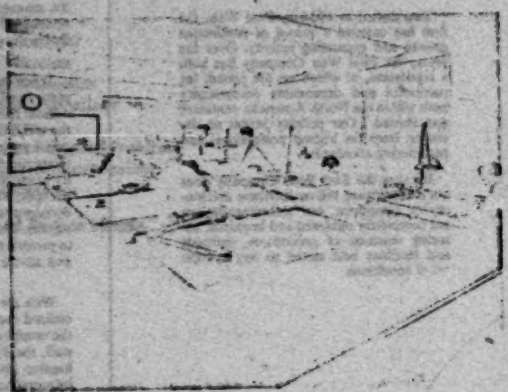
It serves owners and operators of mineral properties, public utilities, railroads, financial institutions, insurance companies, industrial users and government agencies.

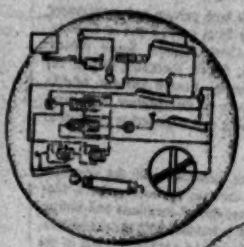
The Paul Weir Company is prepared to execute both field work and/or office work as required. Teams of selected specialists can be provided for short-term assignments in the field or in the office, or fully integrated technical teams can be put in the field and maintained any place in the world for comprehensive long-term projects.

In the development of operating projects—and especially those located in newly developing areas of the world—control practices for labor, materials and maintenance are established as required to fit local conditions in order to achieve effective preventive maintenance and maximum effectiveness and economy of each facility involved. Training seminars are conducted for local supervisory personnel as required to assure effective implementation of such practices and programs.

For many clients, the Paul Weir Company has undertaken responsibilities beyond those associated with engineering services, such as the selection of personnel for top management and operating positions.

On the following pages are specific examples of what we do, which may serve as suggestions to our clients of ways in which we might be of service.





The services available to Weirco clients range from exploration and mapping of virgin deposits through any or all phases to final development of a project at full production level.

Geology and Exploration

Reconnaissance; field geology, mapping; supervision of drilling; sampling; interpretation of results.

Investigations, Surveys, Reports, Recommendations

Valuations and appraisals of physical and intangible property; analyses of virgin or active properties; overall economic and resource surveys; complete project feasibility studies, including engineering aspects, transportation, market, and projected costs; investigations of and recommendations on special problems or specific phases of operation or project.

Engineering and Design

Design and development of details of mines and mine plant; preparation of engineering drawings for installation and construction; determination of specifications and bills of material; engineering cost estimates.

Development and Construction

Recommendations, scheduling, coordination, organization and administration of development and construction; preparation of contracts and purchase orders; direct or advisory supervision of construction and erection; inspection and examination of and reports on construction and construction programs; supervision of acceptance tests; training of operating, maintenance and supervisory staff.

Mechanization

Determinations of potential extent, economic effect and practicable application of mechanized methods; recommendations on most appropriate types of equipment; design and supervision of installation of mining systems; critical analysis for improvement of methods; establishment of preventive maintenance programs and training of personnel.

Beneficiation

Investigation of coal and mineral preparation and beneficiation problems; determination of economic effect of and methods for quality improvement; development of flow sheets and designs; selection of facilities and supervision of erection and acceptance tests; research on solid fuel utilization and coal carbonization.

Management, Supervision and Administration of Operations

Administration and supervision of all phases of mining operations, either direct or advisory; organization of operating staff and selection of personnel; periodic review of operating policies and problems.

1853

EXPERIENCE

The Paul Weir Company has performed consulting and engineering services for numerous operating companies of all sizes. Specialized technical services have also been provided to a large variety of interests such as railroads, public utilities, financial groups and institutions. We have served the U. S. Departments of Interior, Health, Education and Welfare, and Justice; the Army Corps of Engineers; the Atomic Energy Commission; and various executive agencies of the government concerned with Foreign Aid.

Domestic assignments have been carried on throughout the U.S.A.

On work abroad our clients include both private and government interests. Foreign assignments have been carried out in Canada, Mexico, Brazil, Colombia, Chile, Great Britain, South Africa, North Africa, Australia, Indonesia, South Vietnam, Korea, the Philippines, Portugal, Turkey, Germany, France and the Middle East. Additionally, various members of our present staff have been personally associated with mining and engineering projects in other countries.

The Paul Weir Company has been associated with the investigation and development of coal and mineral deposits under a wide variety of physical occurrences, geographical locations and indigenous economic conditions. Our staff is familiar with the equipment, methods and techniques available from and applied in most of the industrially advanced nations. This broad experience can be utilized to find the most suitable and practicable answers to your problems.

1854

TYPICAL ASSIGNMENTS DOMESTIC AND FOREIGN

- *Mining Companies*
- *Financial Institutions*
- *Utilities*
- *Industrial Users*
- *Railroads*
- *Government Agencies*
- *and Others*

Supervised drilling program to establish reserves; layout and design of new shaft mine and preparation plant, followed by supervision of shaft sinking, mine development and surface construction. For a mining company.

Retained by a major chemical company for advisory services on all phases of mining of deep seam coal, a sodium carbonate mineral. Written reports on the development of mining methods, applications of equipment, and forward planning for production of this unique raw material for soda ash.

As part of a joint industrial group serving as general advisors and supervisors for overall economic and industrial development on a national level, Wilbur had responsibility for all services encompassing the mining field, including coal, ferrous and non-ferrous minerals. Resources investigated included uranium, lignite, lead, zinc, silver, gold, copper, iron, graphite, nickel and pyrite.

Modernization of mining in pitching beds, including recommendations for mechanization, haulage and haulage-slot programs with estimates of capital and operating costs. For a mining company in Canada.

TYPICAL ASSIGNMENTS DOMESTIC and FOREIGN
(continued)

Determination of source, costs of development and production of raw materials for a sulphuric acid plant, including surveying, mapping, and setting up a diamond drilling program.

Investigation of optimum coal basin by drilling program, followed by determination of mining and transportation costs to power plant, with comparison of reserves and competitive costs from other sources. A utility company.

A Welsco team composed of specialists in mining, beneficiation, mechanical and electrical engineering served as principal consultants (resident in the field) on the overall development and modernization of a coal field. Services also included training of local personnel in safety, maintenance and industrial engineering practices. The initial project involved a capital investment of more than 300 million dollars. Starting in late 1949 Welsco's services have been retained on subsequent expansion programs projected to 1975.

Investigation and report on conversion of shallow underground gypsum mine to a stripping operation, including recommendations on equipment, techniques, operating methods and costs.

For a cement plant, assignment included geological survey, supervision of core drilling and sampling, and reserve of all raw materials reserve findings to plant expansion. Studies included availability of fuel, power and water, and economic factors.

Feasibility study to evaluate existing coal strip mining operation, and analyze all transportation, marketing and economic factors related to possible expansion. Based on conclusions, recommendations for production expansion including mine design, equipment, method of operation, preparation plant, transport and handling facilities, and capital and operating cost estimates.

Investigation of strippable reserves followed by recommendations for operation and transportation and handling from mine plant to rail and river loading points. For a mining company.

Nation-wide analysis of coal reserves suitable for synthetic liquid fuel manufacture for United States Department of the Interior and Army Corps of Engineers.

For a lead smelter, ascertain tonnages, grades of ore and concentrates for profitable operation. Study and recommend improvements in facilities, operation and management.

1856

Critical review of all major areas of coal and lignite availability, nation-wide, for guidance of major oil company in evaluating studies of manufacture of chemicals and synthetic fuels, with determination of comparative data on quality, mineability and potential cost.

Mapping and geological exploration in a remote region to establish reserves, mining possibilities and economic justification for production and basic use of coal deposits under conditions of national economy. Followed by resident team of engineers (mining, mechanical, construction, transportation) to provide technical services on development of mine and facilities.

Detailed survey of management policy, organizational structure and personnel performance for multiple-mine producer, with critical rating of existing staff and recommendations for improvements in organizational framework.

At request of a private company, Weirco principals analyzed conditions and evaluated two government-owned mines for submission of tender to purchase.

Certification of strippable and underground reserves for multiple-mine producing company having operations in six states, for use in registration statement required by Securities and Exchange Commission.

Complete design, specifications and supervision of construction of 22,000-ton bulk storage warehouse for salt products, adapted for shipments received by rail, truck or water.

Analysis of multiple-mine anthracite company's practices and reserves, followed by recommendations on future programs for modernization of mines and plant facilities, decentralization of maintenance and repair, reduction of overhead, retrenchment in selected high-cost operations, sales policies, contract mining and labor relations.

A Weirco team installed and supervised operation of an experimental mine for determination of most economic methods of mining and appropriate types of equipment under conditions of unique coal occurrence.

Preparation of flow sheets, design and specifications for new coal preparation plants and accessory facilities for various major coal producers, steel companies and utility interests, foreign and domestic.

Special studies and investigations of mineral beneficiation problems, including development of recommended flow sheets for beneficiation plants.

Special study of coal pipelining, including factors of coal supply, utilization, economics, and competitive position as transport medium.

Appraisal and evaluation of all physical and intangible assets of two multiple-mine companies, including reserves and operating properties, for purpose of merger negotiations.

For acquisition of a major coal company by a major oil company, assigned by the interests to make the engineering and economic evaluation of coal company reserves, mines and mine plant, including projection of long-range production tonnage and operating costs. An equivalent assignment was executed for the financing interests for acquisition of a second major coal company by a large metal-mining company.

Weirco team of engineering and operating specialists (resident on site) served as consultants and advisers on underground and open-pit mining operations and expansion at a copper mines abroad.

For a large coal mine producer, study, specifications, engineering layout and design of storage facilities and live-walls overhead belt-conveying system.

Engineering design of two mine shafts and inclined shaft; specifications and engineering layout for crushing and screening station, belt-conveyor system, stockpiling and barge-loading facilities (5,000 t.p.h. capacity) for major coal-mining company.

Detailed field exploration program to establish quantity and quality of high-grade metallurgical coal reserves; flow sheet and specifications for preparation plant; check of all design and structural drawings.

PAUL WEIR COMPANY

PERSONNEL

The permanent staff of Paul Weir Company, based in Chicago, is a highly integrated team of experienced specialists of diverse capabilities—consultants, managers, engineers, geologists, designers, a comptroller and purchasing agent. Trained field engineers and supplementary technical staff are added as needed for projects anywhere in the world.

Through our years of steady growth we have selected our personnel carefully, with emphasis on technical training, practical experience, professional aptitude, sound judgment and analytical ability. Their accomplishments and abilities are measured by the results achieved for our clients (attested by the fact that much of our work is repeat business from a satisfied clientele) and by the recognition given them by their fellow professionals.

PROFESSIONAL MEMBERSHIPS INCLUDE:

American Institute of Consulting Engineers
American Institute of Mining, Metallurgical and Petroleum Engineers
American Institute of Professional Geologists
American Mining Congress
Coal Mining Institute of America
Illinois Mining Institute
Institution of Mining Engineers (U.K.)
Geological Society of America
Mine Inspectors Institute of America
Mining and Metallurgical Society of America
National Society of Professional Engineers
Rocky Mountain Coal Mining Institute
Society of Economic Geologists
Western Society of Engineers
American Association for the Advancement of Science
American Chemical Society
American Ordnance Association
National Association of Colliery Managers (U.K.)

PAUL WEIR

Chairman of The Board

Mr. Paul Weir received B.S. and E.M. degrees (Mining Engineering) from Pennsylvania State University. He is a Registered Professional Engineer, and is listed in *Who's Who in Engineering*.

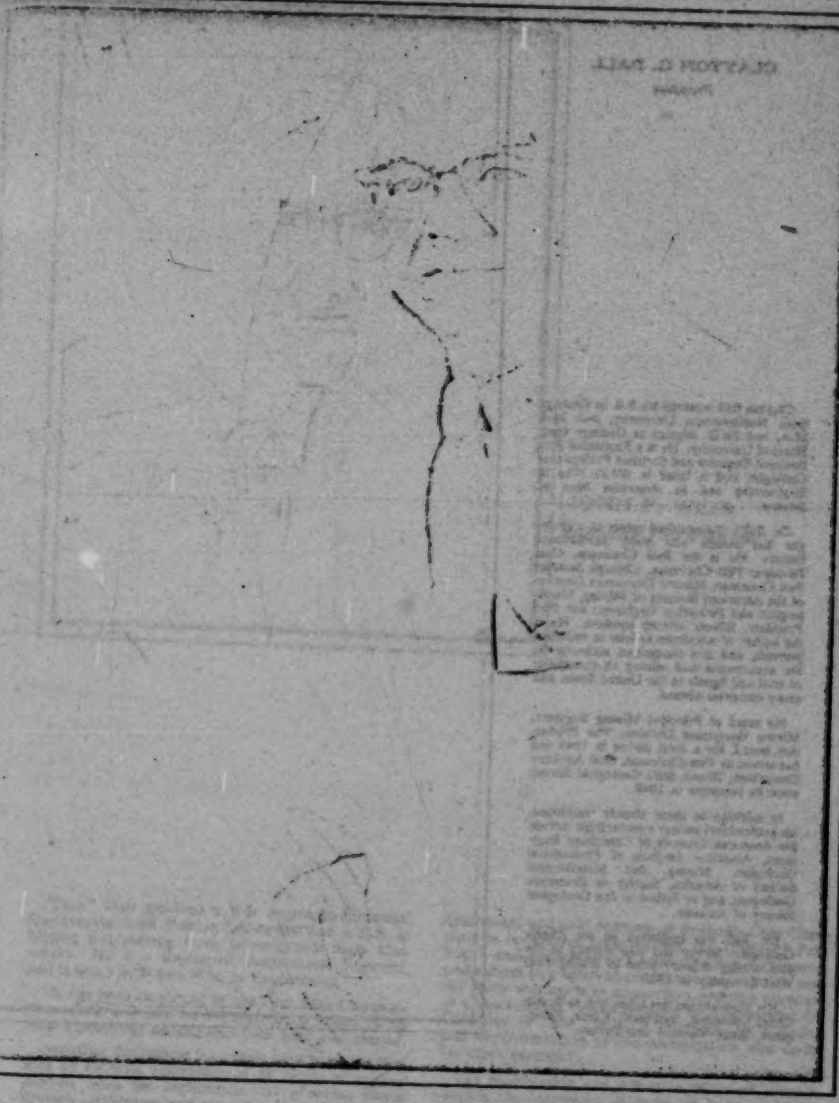
Mr. Weir, founder of the company, is recognised internationally for his achievements and contributions to the mining industry. He is considered one of the outstanding authorities on the valuation of mines. He was the recipient in 1949 of the Erskine Ramsay Gold Medal Award given by the American Institute of Mining Engineers for outstanding work and service to the coal mining industry. Pennsylvania State University rewarded him with its Distinguished Alumnus Award in 1954. In 1957, Mr. Weir was elected to Honorary Life Membership in the Institution of Mining Engineers (United Kingdom).

Prior to the formation of Paul Weir Company in 1936, Mr. Weir served as engineer, Chief Engineer, and Vice President in Charge of Operations of an Illinois coal mining company.

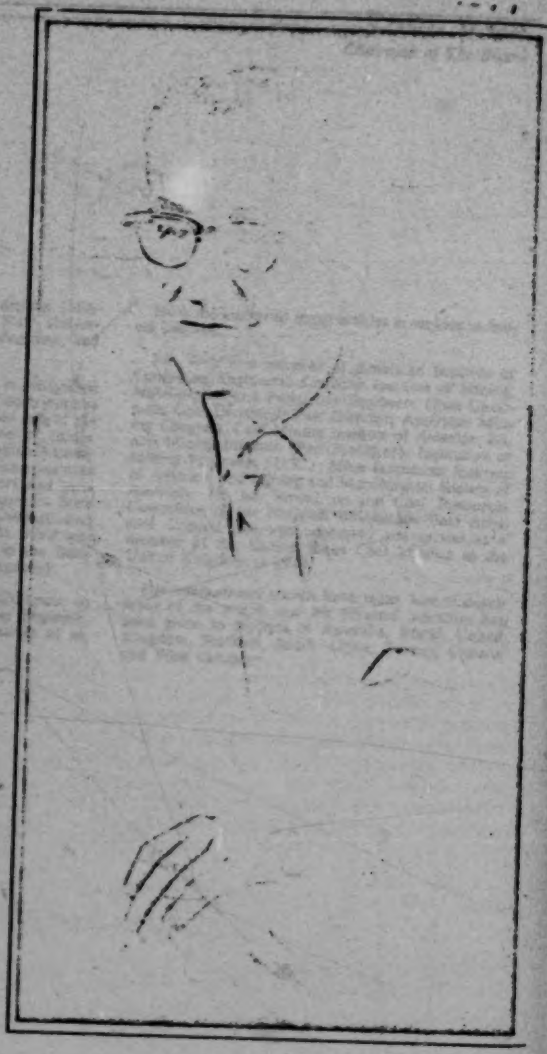
He is the author of many articles in various technical journals.

Mr. Weir is a member of American Institute of Consulting Engineers; American Institute of Mining, Metallurgical and Petroleum Engineers (Past Chairman, Coal Division); Past Director, American Mining Congress; Coal Mining Institute of America; Illinois Mining Institute (Past President); Institution of Mining Engineers (U.K.); Mine Inspectors Institute of America; and Mining and Metallurgical Society of America. He has served on the Coal Resources Committee of the National Bituminous Coal Advisory Council and was appointed and served as a member of the United States Coal Mission to the United Kingdom in 1944.

His international travels have taken him to many areas of the world, and his personal attention has been given to projects in Australia, Brazil, United Kingdom, Scotland, South Africa, Turkey, Canada and West Germany.



CLAYTON G. BALL
President



Clayton Ball received his B.S. in Geology from Northwestern University, and both M.A. and Ph.D. degrees in Geology from Harvard University. He is a Registered Professional Engineer and Certified Professional Geologist, and is listed in *Who's Who in Engineering* and in *American Men of Science*.

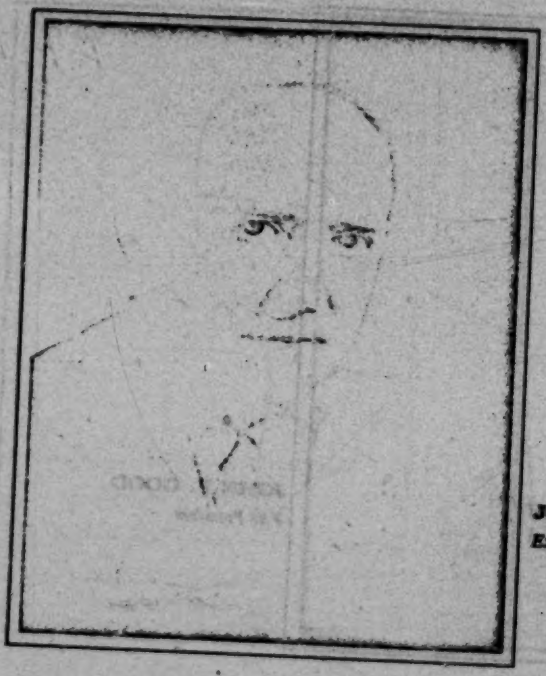
Dr. Ball's distinguished career as a geologist has covered nine years professional service. He is the Past Chairman, Coal Division; Past Chairman, Chicago Section; Past Chairman, Mineral Economics Division of the American Institute of Mining, Metallurgical and Petroleum Engineers; and Past President, Illinois Mining Institute. He is the author of numerous articles in technical journals, and is a recognized authority on the occurrence and mining characteristics of coal and lignite in the United States and many countries abroad.

He served as Principal Mining Engineer, Mining Equipment Division, War Production Board, for a short period in 1943 and has served as Vice-Chairman, Coal Advisory Committee, Illinois State Geological Survey since its inception in 1948.

In addition to those already mentioned, his professional society memberships include the American Institute of Consulting Engineers, American Institute of Professional Geologists, Mining and Metallurgical Society of America, Society of Economic Geologists, and as Fellow in The Geological Society of America.

Dr. Ball was employed by the Illinois Geological Survey and also worked in the coal mining industry prior to joining Pauli Weir Company in 1937.

His work abroad has taken him to Brazil, Chile, Colombia, Indonesia, Korea, Philippines, South Vietnam and Turkey.



JOHN P. WEIR
Executive Vice President

"Jack" Weir received a B.S. degree in Chemical Engineering from Purdue University and a B.S. in Mining Engineering from Pennsylvania State University. He is a Registered Professional Engineer, and is listed in *Who's Who in Engineering*.

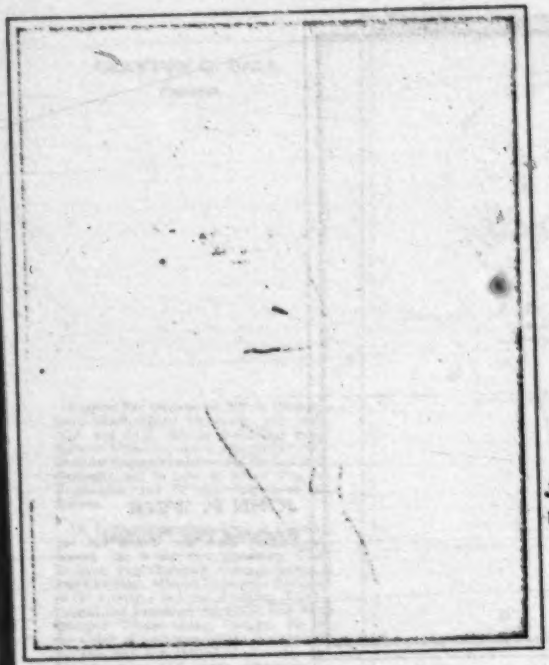
He has been employed by the Paul Weir Company since 1949 and has served Weirco on many of its most demanding assignments both here and abroad.

Activities throughout his career have provided him with an intimate knowledge of all facets of mining projects from the exploration and planning stages through application and operation of equipment and mining methods. Strata control has been one area of his major interests. The preparation of feasibility reports and reports for financing have often been his responsibility.

The Paul Weir Company prepared an independent engineering evaluation and economic study of the coal mines and coal reserves of Peabody Coal Company in connection with the sale (in 1968) of Peabody's coal properties to Kennecott Copper Corporation subject to a reserved production payment. A similar study was made in connection with the purchase of Consolidation Coal Company by Continental Oil Company in 1966. In both instance, the direction and implementation of the investigation was under his close control.

His membership and offices in technical societies include the American Institute of Mining, Metallurgical and Petroleum Engineers (serving as a Member of the Executive Committee, Coal Division), a Past President of the Illinois Mining Institute, Institution of Mining Engineers (U.K.), Rocky Mountain Mining Institute, and Western Society of Engineers.

His foreign assignments have included Australia, Germany and South Africa.



JOHN E. GOOD
Vice President

Mr. Good received his B.S. degree in Mining Engineering from Virginia Polytechnic Institute. He subsequently taught extension school classes in mining for Pennsylvania State University for several years. He joined Paul Weir Company in 1950.

Before joining Paul Weir Company, he had been first employed as an engineer by a multiple-mine coal company in Pennsylvania, and was night superintendent of a large coke oven plant.

He spent two years in Peru, employed by Cerro de Pasco Copper Corp. as an engineer and operating mine foreman. After Peru he received an assignment for mining investigations in Brazil by the United States Government under auspices of the (then) War Production Board and successor agencies, and later was employed by the U. S. Bureau of Mines and assigned as advisor to the Brazilian National Department of Mineral Production. After five years in Brazil on these assignments, Mr. Good acted as a private consultant to various foreign and American firms on investigations and reports on mining properties, and was retained by the U. S. Bureau of Mines on a consulting basis in connection with preparation of certain foreign mining industry reports and publications.

After joining Weirco, he spent eight years as Resident Chief Engineer of a Weirco team of engineers in Turkey acting as principal consultants to the Turkish Government on development of the Zonguldak Coal Basin. This project involved all phases of large-scale multiple mine development, from initial studies and recommendations through specifications, layout and general design, construction and putting plant and facilities into operation.

Since returning to home office base in 1958, in addition to administrative responsibilities on foreign projects, he has executed specific assignments on foreign and domestic projects involving investigations, feasibility studies, mine development planning and technical reports. Since 1958 his activities on foreign projects have included Mexico, Colombia, Indonesia, South Vietnam, Portugal and the Middle East.

Mr. Good is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers and the American Institute of Consulting Engineers. His honorary society memberships include Tau Beta Pi and Omicron Delta Kappa.

RAYMOND E. ZIMMERMAN
Vice President

Mr. Zimmerman received his B.S. in Mining Engineering and his E.M. degree from Pennsylvania State University. He is a Registered Professional Engineer. He joined Paul Weir Company in 1954.

His professional career includes extensive experience in coal preparation and utilization, mineral beneficiation, coal carbonization, testing, evaluation, specifications, cost projections, and direction of research. His experience also includes the operational aspects of plants and processing facilities.

Mr. Zimmerman was responsible for an exhaustive research of European coal preparation practices which has had significant influence on up-dating procedures in England, Holland, Belgium and Germany.

He is listed in *Who's Who in Engineering* and *American Men in Science and Education*. He is the co-author of the classic treatise *Coal Preparation* published by the American Institute of Mining Engineers which is now in its third edition. Many of his technical writings pertaining to coal preparation, processes and mineral preparation have been published in technical magazines and other publications.

His professional society memberships include the American Institute of Mining, Metallurgical and Petroleum Engineers; Illinois Mining Institute; Institution of Mining Engineers (U.K.); American Association for the Advancement of Science; National Society of Professional Engineers; and American Ordnance Association. His honorary society memberships include Sigma Gamma Epsilon (Mining), Sigma Xi (Research and Science), and Phi Lambda Upsilon (Chemistry and Physics).

Mr. Zimmerman's foreign assignments have included projects in Europe, Indonesia, Iran, Mexico, Peru, Japan and Turkey.

ERWIN GAMMETER

Vice President

Mr. Gammeter received his B.S. in Mining Engineering and his E.M. degree from Missouri School of Mines and Metallurgy.

He has been associated with the Paul Weir Company since 1945, with a leave of absence from 1952 to 1956 to serve the Hamilton Overseas Contracting Company in Turkey as Project Manager on a major tunnel-driving project on the coast of the Black Sea.

He brought a wealth of experience to his work at Weirco with a background as mining engineer for multiple-mine coal companies in Illinois, Kansas and Oklahoma.

His specialties are mine development and mine construction.

From 1958 to 1961 he served as Department Manager, Coal Mining, for a team of Paul Weir Company engineers and geologists in Korea, serving as Consultants to the Korean Government.

Mr. Gammeter is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers; the Illinois Mining Institute; and Tau Beta Pi honorary society.

Foreign assignments on which he has been actively engaged include Brazil, Korea and Turkey.

DAVID J. KACHIK

Vice President

Mr. Kachik received his B.S. in Mining Engineering and his M.S. in Mining Geology from Pennsylvania State University.

He was a former Instructor in Mining and a Research Associate at Pennsylvania State University, and has been with Weirco since 1949. He is an expert in the fields of mine operation and production, mine management, and drilling programs with regard to underground operations. An area of particular interest to Mr. Kachik is the application of longwall mining methods.

He is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers; Illinois Mining Institute; and Coal Mining Institute of America.

Foreign assignments have taken him to England, South Africa and South Vietnam.

DONALD H. DOWLIN

Vice President

Mr. Dowlin received his Engineer of Mines degree from the Colorado School of Mines, and is a Registered Professional Engineer. He joined the Paul Weir Company in 1964.

Earlier in his career he was employed by various major coal companies, during which period he developed extensive experience in underground mining, being advanced into responsible positions in both the engineering and production fields. His experience included coal prospecting and evaluation of reserves, mine design and operation, plant layout and design, property evaluations and mine management.

Immediately prior to his employment with the Paul Weir Company he was employed by a nationally-known engineering and consulting firm working in the engineering, design and construction of coal mining installations. At this time he served as a Project Engineer with responsibilities from initial planning to final operation. During this employment he also represented his firm as coal consultant to a major steel company in India.

His further experience and assignments with the Paul Weir Company have been in the same areas of engineering and professional activities as those previously discussed.

He is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers, and the Illinois Mining Institute.

GEORGE W. BOULTER

Mr. Boulter received his B.S. in Mining Engineering from Montana School of Mines, and is a Registered Professional Engineer.

His specialty is strip, open-pit and quarry mining, with world-wide experience on projects of major scope.

Earlier in his career he was employed as Mining Engineer and Mine Superintendent by major metal mining companies in western United States and later as Mining Engineer and Project Manager by a major western railway company. At the time he joined Weirco in the early part of 1968, he was Manager, Mining Division for a major manufacturer of heavy earth-moving equipment.

As an authority on open-pit or surface mining, Mr. Boulter has extensive experience with operations of this type under a wide variety of conditions and a broad spectrum of equipment applications. In addition to familiarity with most of the open-pit operations of size on the North American continent, he has carried out assignments on many projects abroad, in areas including Australia, Africa, the Middle East, Tasmania, New Zealand, Surinam, Guyana, New Guinea, India, Brazil, Sweden, United Kingdom and West Germany.

He has contributed articles connected with his specialty to various technical publications and is the author of the chapter on Cyclical Methods—Draglines in the Seely W. Mudd series authoritative book on surface mining. He is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers; Illinois Mining Institute; and Northwest Mining Association.

GERALD C. CLARK

Mr. Clark received B.S. and M.S. degrees in Mining Engineering from West Virginia University. He is a Registered Professional Engineer.

He joined Paul Weir Company in 1965. Prior to that time he had been Chief Engineer for a coal company and was employed by the American Mining Congress as Mechanization Engineer at the time he came to Weirco.

His experience with operational problems, underground mining methods and equipment applications under a variety of conditions, and the economic aspects of mine development and operation provides the basis for his demonstrated capabilities and contributions to many of Weirco's most demanding projects.

He has contributed various articles to technical publications, and is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers; the West Virginia Society of Professional Engineers; and the Illinois Mining Institute. He is also a member of Sigma Gamma Epsilon, honorary earth's science society.

MARTIAL P. CORRIVEAU

Martial Corriveau received his B.S. degree in Metallurgical Engineering from Michigan College of Mining and Technology, and his S.M. in Metallurgy from Massachusetts Institute of Technology. He also received a Professional Engineering degree of Metallurgical Engineer from Michigan College of Mining and Technology. He is a Registered Professional Engineer. He joined Paul Weir Company in 1968.

Mr. Corriveau's experience is extensive in the fields of mineral dressing and processing, coal and coke analysis and testing, preparation and quality control, and research. He has been employed as a metallurgist with U. S. Smelting, Refining and Mining Company; as a Research Engineer with Battelle Memorial Institute; as Research Assistant at Massachusetts Institute of Technology; and as Associate Research Professor at Virginia Polytechnic Institute.

He held the position of Preparation Engineer and Manager of Quality Control with a multiple-mine coal producing company, and prior to joining Weirco he was Technical Advisor and Director, Commercial Testing and Engineering Co., responsible for all company-wide technical aspects of analysis and testing of coal, coke and ore minerals, and establishment of a new Air and Water Pollution Department.

Mr. Corriveau is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers. He is a member of the Coal Preparation Committee, American Mining Congress and the American Society for Testing Materials (ASTM) Committee on Coal and Coke. His honorary society memberships include Tau Beta Pi and Sigma Xi.

RICHARD W. STOREY

Mr. Storey received his B.S. in Civil Engineering from the University of Kentucky. He is a Registered Professional Engineer (Mining and Civil). He joined Paul Weir Company in 1967.

During his career, he has held responsible positions in the U.S.A. with substantial coal mining firms as Mining Engineer, Division Engineer and Chief Engineer. Prior to joining Weirco he was employed on overseas assignment as Mining Engineer and advisor to the Korean coal industry on problems including exploration, development, operation, and processing and utilization.

His assignments with Paul Weir Company have been focused in the areas of feasibility studies, planning and design, mine operation problems and development of mining properties.

He has contributed articles to technical journals on underground auger mining and continuous mining in eastern Kentucky coal fields. He is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers, and the Illinois Mining Institute.

JAMES E. McNULTY, JR.

Mr. McNulty received his B.S. in Geology from the University of Iowa. He joined Paul Weir Company in 1961.

He is a mining geologist and has had intensive field and office experience in exploration and supervision of drilling and sampling programs, interpretation of exploration, drilling and analytical data, mapping, evaluation of underground mining conditions, and establishment of reserves.

He is a member of the American Institute of Mining, Metallurgical and Petroleum Engineers, and the Illinois Mining Institute.

WILLIAM A. SMITH

Mr. Smith received his B.S. degree in Mining Engineering from the Royal College of Science and Technology (Glasgow). He is a Chartered Engineer (U.K.).

He joined Paul Weir Company in 1966. His areas of special capabilities are shaft sinking and underground development work.

Mr. Smith has had extensive experience throughout Great Britain where he served as Project Manager for Cementation Company Ltd. His work also took him to India on major shaft sinking and mine development projects. Prior to joining Weirco he had been assigned to U.S.A. as Area Manager in charge of shaft sinking projects for Cementation Company.

He is an Associate Member of the Institute of Mining Engineers (U.K.); a member of the National Association of Colliery Managers; the American Institute of Mining, Metallurgical and Petroleum Engineers; and the Illinois Mining Institute.

JOHN S. SNYDER

Comptroller

Mr. Snyder received his M.B.A. from the University of Chicago. He has been with Paul Weir Company since 1952.

Prior to joining Weirco, his experience included positions as District Controller for a multi-company engineering and heavy equipment manufacturing corporation and Comptroller for an electronic components manufacturing firm. He has had administrative responsibilities in mining operations.

His responsibilities with Weirco encompass all financial aspects of the organization including those connected with overseas operations. Purchasing, office personnel and office administration are under his supervision.

On projects involving economic and financial analyses and projections, Mr. Snyder's services are employed on behalf of clients as well as on Weirco's internal affairs.

He is a member of the Illinois Mining Institute.

JOHN L. DOBELBOWER

Mr. Dobelbower is a Mechanical Engineer, receiving his B.S. degree from Pennsylvania State University. He joined Paul Weir Company in 1964.

Prior to joining Weirco he had 14 years experience with a prominent company in the cement, lime and construction aggregate industry. Advancing from Mine and Plant Engineer, he held increasingly responsible positions as Project Manager, Budget Director and Manager of Operations in various divisions of the company. His experience included all phases of engineering, production, planning, operations and management. He has had direct experience on both engineering and operational levels with a wide variety of equipment used in underground and surface mining operations.

Mr. Dobelbower's experience and capabilities earned him an assignment as Project Manager of a team of Weirco engineers resident in Turkey as engineering consultants to the Turkish Government on a large scale expansion phase of the public sector coal mining activities. In addition to the supervisory responsibilities of a Project Manager, his work since joining Weirco has centered around planning, budgeting, and problems related to the engineering and application of equipment for mining and mining facilities.

HENRY D. OLSON

Mr. Olson is an Electrical Engineer, with a B.S. degree from the University of Minnesota. He joined Paul Weir Company in 1967.

Prior to his employment by Weirco, he had first served as a Field Service Engineer with the Electro-Motive Division of General Motors Corporation.

Later employed by Western Knapp Engineering Division of Arthur G. McKee and Company, he served as Electrical Design Engineer, provided field engineering services during construction and start-up phases of large industrial plants and facilities, and was Project Electrical Engineer on a multi-million dollar plant expansion.

Mr. Olson served with Jones and Laughlin Steel Corp. as Chief Electrician, New York Ore Division, engaged in the mining and beneficiation of iron ore. In charge of a staff of 27 electricians and their supervisors, he was responsible for all electrical design and construction, and the maintenance of all electrical equipment used in the mining operations. This included incoming 115KV lines through to the AC and DC machinery.

Upon joining Weirco, Mr. Olson was assigned to a major project in Turkey as Electrical Engineer on a Weirco team providing engineering services to the Turkish Government on a large scale mining expansion program. His activities with Weirco have continued to center around the engineering and technical problems related to electrical equipment, systems and facilities used in the mining industry.

He is a member of the Institute of Electrical and Electronic Engineers.

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, and FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

JURISDICTIONAL STATEMENT

Filed 9/8/72

OPINION BELOW

The opinion of the district court (App. A, *infra*, 1a-66a) is reported at 341 F. Supp. 534.

JURISDICTION

The opinion and judgment of the district court was filed on April 13, 1972. The notice of appeal to this Court (App. B, *infra*, 67a-68a) was filed on

June 7, 1972. On July 7, 1972, Mr. Justice Rehnquist extended the time for docketing an appeal until September 8, 1972. The jurisdiction of this Court is conferred by Section 2 of the Expediting Act (15 U.S.C. 29). *United States* v. *El Paso Natural Gas Corp.*, 376 U.S. 651.

QUESTIONS PRESENTED

1. Whether, under Section 7 of the Clayton Act, coal is a relevant line of commerce for the purpose of assessing the competitive effects of the combination of the second and fifth largest coal producers in Illinois, and the second and sixth largest in the Eastern Interior Coal Province Sales Area.

2. Whether Illinois and the Eastern Interior Coal Province Sales Area are relevant sections of the country for purposes of assessing the competitive effects of such a combination.

3. Whether, in assessing anticompetitive effects under Section 7 of the Clayton Act, it is proper for a court to consider only whether at the time of trial the acquired firm could still survive as an independent entity, without determining the competitive potential of that firm that was cut off by the acquisition.

4. Whether the trial court committed clear error in finding that the acquired company would not be able economically to mine its uncommitted strip coal reserves, could not develop the expertise to mine its own deep coal reserves, and could not acquire and develop further coal reserves.

STATUTE INVOLVED

Section 7 of the Clayton Act, 38 Stat. 731, as amended, 64 Stat. 1125, 15 U.S.C. 18, provides in pertinent part:

> No corporation engaged in commerce shall acquire, directly or indirectly, the whole or any part of the stock or other share capital and no corporation subject to the jurisdiction of the Federal Trade Commission shall acquire the whole or any part of the assets of another corporation engaged also in commerce, where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition, or to tend to create a monopoly.
>
> * * * * *

STATEMENT

The United States instituted this civil antitrust case, contending that the acquisition of the stock of United Electric Coal Companies ("UEC") by Material Service Corporation ("Material Service") and its successor, General Dynamics Corporation ("General Dynamics), violated Section 7 of the Clayton Act (15 U.S.C. 18). It alleged that actual and potential competition in the Illinois and Eastern Interior Coal Province Sales Area coal markets might be substantially lessened by the acquisition. After a trial on the merits, the district court held there was no Section 7 violation.

A. The Coal Industry

The coal industry has undergone a substantial transformation in the postwar period. It lost the railroad market entirely to the diesel engine. It lost most of the home heating, and a substantial portion of the industrial, market to gas and oil (App. 11a-12a). Total coal production in the United States dropped from 441 million tons in 1947 to 278 million tons in 1954 (DX 85, Table I).[1] Since 1954 the electric utility market has become the principal mainstay of the coal industry, and by 1968 it accounted for 72 percent of total national coal consumption (DX 85, Table I). The utilities' rapidly increasing energy demands have led to a resurgence of coal production since 1954. By 1968 the United States produced 408 million tons of coal (DX 85, Table I), a production figure which is estimated to be increasing at the rate of 3.1 percent per year through 1980 (GX 232, p. 41).

Coal resources are concentrated in four distinct regions of the United States. The region whose sales area the government claimed constituted one of the "section[s] of the country" (15 U.S.C. 18) in which competition was affected by the acquisition is the Eastern Interior Coal Province, which encompasses

the central and southern two-thirds of Illinois and much of southwestern Indiana and western Kentucky.[2] All of the mines of the acquired and acquiring companies are now located in Illinois within the Eastern Interior Coal Province.

The leading producers have accounted for an ever-increasing share of the total production in the Eastern Interior Coal Province. In the 10 years between 1957 and 1967 the top two firms increased their share of the region's total production from 29.6 percent to 48.6 percent, the top four increased their share from 43.0 percent to 62.9 percent, and the top ten increased their share from 65.5 percent to 91.4 percent (GX 86). During the same period, in the State of Illinois, the top two producers increased their share of total Illinois production from 35.5 percent to 52.9 percent, the top four increased their share from 52.2 percent to 75.2 percent, and the top ten increased their share from 81.6 percent to 98.0 percent (GX 73). This period was also marked by a sharp decline in the number of producers. A total of 145 companies were producing coal in Illinois in 1957; only 39 companies remained in 1967 (GX 73).

---

[2] The other three are: (1) The Eastern Coal Province of western Pennsylvania, West Virginia, eastern Kentucky and parts of Ohio, Tennessee and Alabama; (2) The Western Interior Coal Province, comprised of central Iowa, northern and western Missouri and eastern Oklahoma; and (3) scattered deposits in Montana, Wyoming, Colorado and Utah (GX Kurtz Dep. Ex. 10, p. 47).

B. The Acquiring Company—General Dynamics, Material Services, and Freeman

General Dynamics[3] became the nation's fifth largest coal miner as a result of its acquisition of Material Service in 1959 (App. 3a). Material Service was then engaged in producing and supplying building materials, concrete, coal and limestone. It then owned all of the stock of Freeman Coal Mining Corporation (App. 3a).

In 1959 Freeman produced approximately 6.9 million tons of coal at mines located in Illinois (GX 64) and accounted for 15.1 percent of Illinois production (GX 64) and 7.6 percent of Eastern Interior Coal Province production (GX 77). It was the second largest producer in both areas (GX 64, 77). In 1967[4] it produced 8.4 million tons and accounted for 12.9 percent of Illinois production (GX 72) and 6.5 percent of Eastern Interior Coal Province production (GX 85).

Freeman sold 51.4 percent of its 1965 production (GX 88), 44.0 percent of its 1966 production (GX 89) and 42.3 percent of its 1967 production (GX 90) to customers who also purchased coal from UEC, the acquired Company. These customers consumed

---

[3] General Dynamics is a large and diversified company that depends on government sales for more than 85 percent of its business (App. 2a). It ranked 27th among industrial corporations in the United States in 1968, with total sales of $2,662,238,000. (*Fortune Magazine*, May 15, 1969, p. 168.)

[4] UEC became a wholly owned subsidiary of General Dynamics at the beginning of 1967 (App. 9a).

37.4 percent of Freeman's 1965 output, 37.0 percent of its 1966 output and 39.8 percent of its 1967 output at facilities which also consumed substantial portions of UEC's output in those years (see GX 91 and *infra*, p. 8).

At the time of trial in 1970 Freeman operated four mines in southern Illinois and one mine in central Illinois (DPF 59, 60). All of the Freeman mines were deep mines (App. 6a). Freeman also owned the rights to approximately 484 million tons of deep coal reserves in Illinois (DPF 59).

C. The Acquisition and the Acquired Company (UEC)

Material Service began acquiring UEC stock in 1954 and had increased its holdings to 34 percent by 1959 when Freeman's president, Frank Nugent, was elected Chairman of UEC's Executive Committee (App. 7a-8a). General Dynamics acquired Material Service a few months later and continued to acquire UEC stock. In September 1966 General Dynamics held 66.15 percent of UEC's stock and made a successful tender offer for the remaining shares (App. 8a-9a).

In 1959 UEC produced 3.7 million tons of coal in Illinois (GX 64) and .6 million tons in other parts of the Eastern Interior Coal Province (GX 77) and accounted for 8.1 percent of the Illinois production (GX 64) and 4.8 percent of the Province's production (GX 77). It was the fifth largest producer in Illinois and the sixth largest in the Province. In 1967 it produced 5.7 million tons and accounted for

8.9 percent of Illinois production (GX 72) and 4.4 percent of the Province's production (GX 85).

UEC sold 70.2 percent of its 1965 production (GX 88), 62.1 percent of its 1966 production (GX 89) and 61.6 percent of its 1967 production (GX 90) to customers who also purchased coal from Freeman. These customers consumed 54.7 percent of UEC's 1965 output, 52.9 percent of its 1966 output and 48.2 percent of its 1967 output at facilities which also consumed substantial portions of Freeman's output in those years (see GX 91 and *supra*, p. 7).

At the time of the trial UEC operated three mines in west central Illinois and one mine in southern Illinois (App. 6a). All of the UEC mines were open pit or strip mines (*ibid.*). It has not operated an underground mine since 1954 (App. 7a). In 1970 UEC owned 52 million tons of strip reserves in its existing mines (App. 9a). It also owned 12.6 million tons of strip reserves in the Industry Field in central Illinois and 44.3 million tons of deep reserves in the Round Prairie Field in southern Illinois (DX 60A), and it controlled another 40 or 50 million tons by location in the Round Prairie Field (Tr. 314-318).[5]

UEC has consistently had one of the highest profit

---

[5] Reserves contiguous to those owned, leased or optioned are "controlled by location" if, in order to be mined at all, they must be mined by the holder of the rest of the reserves in the area.

margins in the coal industry.* In 1959 UEC had a net worth of $19.6 million, $2.8 million in working capital and a long-term debt of $1.2 million (GX 24). By 1968, despite the payment of $11 million in dividends to General Dynamics (GX Nugent Dep. Ex. 22, GX 27), UEC had eliminated all long-term debt, had increased its net worth to $26.9 million, and had accumulated $10.7 million in working capital (GX 34).

D. Proceedings Below

The United States filed its complaint on September 22, 1967. The trial was held from March 30 to April 22, 1970, and the district court issued its opinion on April 13, 1972.

The government's theory of the case was that the Freeman-UEC combination was an ordinary horizontal acquisition which created an entity claiming an inordinate share of an increasingly concentrated market. The government contended that coal is an appropriate line of commerce for Section 7 purposes, that Illinois and the Eastern Interior Coal Province Sales Area are appropriate sections of the country,

---

* It was the industry leader in operating income as a percentage of revenues in 9 out of 11 years from 1955 through 1965 in a Standard & Poor's survey of 13 major coal companies (GX 26, p. C76). During the period from 1959 through 1967, UEC realized profits of $24.1 million on sales of $181.2 million (see GX 25). Freeman realized profits of $15.8 million on sales of $289.9 million during the same period (GX Nugent Dep. Exs. 1-9).

and that the combination was likely to produce substantial anticompetitive effects within the relevant markets.[7]

Defendants attempted to show that Freeman and UEC were not actual or potential competitors. To this end, defendants divided the companies' sales into ten geographic areas, based largely on Freight Rate Districts. They contended that Freeman and UEC do not compete in eight of these markets and will not compete in the future in the other two. In addition they claimed that UEC was not a potential competitive force because it could not mine its own uncommitted strip mine or deep reserves, and could not acquire and develop other reserves.

The district court rejected the government's proposed product and geographic markets. It held, after a lengthy discussion of interfuel competition in the electric utility market, that "the energy market is the appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination" (App. 53a). It adopted ten geographic markets proposed by the defendants, consisting of the Commonwealth Edison Company, the Metropolitan Chicago Interstate Air Quality Control Region and utility and non-utility sales areas for coal mines

---

[7] The Eastern Interior Coal Province Sales Area is comprised of Illinois, Indiana, the western half of Kentucky, the western one-third to one-half of Tennessee, the extreme eastern portion of Missouri on or near the Mississippi River, the eastern half of Iowa, southeastern Minnesota, and southern Wisconsin.

located in each of four different Freight Rate Districts (App. 56a-59a).[8]

In addition the district court stated that even if it were to accept the government's geographic markets, the government's "failure to show that a substantial lessening of competition resulted from the United Electric-Freeman combination is fatal to this divestiture action" (App. 59a-60a). The district court's conclusion of a lack of anticompetitive effect rested on subsidiary findings (a) that UEC's reserves of coal for strip mining were small and the government had not shown that it could acquire additional economically mineable strip reserves (App. 63a), (b) that UEC did not have and could not acquire the skill to mine its own expansive deep reserves (App. 65a), and (c) that UEC and Freeman are "predominantly complementary in nature" (App. 61a) because of their different mining techniques, because Freeman produces some dust and metallurgical coal while UEC does not, and because Freeman produces some coal that has a lower sulphur content than the UEC coal (App. 61a-62a).

THE QUESTIONS ARE SUBSTANTIAL

This appeal raises substantial questions concerning the proper criteria for the analysis of product

---

[8] Parts II and III of the district court's opinion (App. 11a-53a), which contain all of the factual findings underlying the court's product and geographic market definitions, consist *verbatim* of Defendants' Proposed Findings of Fact Nos. 138-282 (omitting Nos. 209-210; 217-218; 234-235; 241; 250; 253; 280-281). Compare *United States* v. *El Paso Gas Co.*, 376 U.S. 651, 656-657.

and geographic markets, and the proper standards for assessing the anticompetitive effects, in Section 7 cases. In rejecting coal as a relevant product market, the district court departed from the consistent teachings of this Court that there may be more than a single "line of commerce" relevant for Section 7 purposes. In addition, the district court adopted, as the relevant geographic markets, a patchwork of small "markets" based on the sales area for the freight rate district in which each of the defendants' mines was located, despite the fact that the mines sold more than half of their production outside of those "markets." Finally, the court improperly assessed the competitive potential of UEC, the acquired company, by looking at the state of the company's resources and prospects at the time of trial in 1970 rather than at the time of acquisition in 1959. And, even in making this determination, the trial court committed clear error in finding that UEC would not be able economically to mine its uncommitted strip reserves, could not develop the expertise to mine its own deep reserves, and could not acquire and develop any others.

1. Whether or not the trial court was correct in finding the "energy market" (App. 53a) to be a "line of commerce," it erred in rejecting coal as a relevant submarket. As this Court clearly explained in *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 325:

> The outer boundaries of a product market are determined by the reasonable interchangeability of use or the cross-elasticity of demand between

> the product itself and substitutes for it. However, within this broad market, well-defined submarkets may exist which, in themselves, constitute product markets for antitrust purposes. * * * The boundaries of such a submarket may be determined by examining such practical indicia as industry or public recognition of the submarket as a separate economic entity, the products' peculiar characteristics and uses, unique production facilities, distinct customers, distinct prices, sensitivity to price changes, and specialized vendors. * * *

Brown Shoe thus recognizes that, on the one hand, defining a Section 7 "line of commerce" only to include all substitutes may frustrate the congressional purpose by obscuring the effect of a merger between sellers of any one of the substitutable products; while, on the other hand, defining it only in terms of a single product may equally frustrate the congressional purpose by excusing mergers between sellers of substitutes. In view of the expressed congressional desire to prevent mergers which may substantially lessen competition in *any* line of commerce, the Court concluded that the effects of a merger must be examined not only in the broader product market, but also "in each such economically significant submarket * * *" (*ibid.*).

The record demonstrates that coal satisfies all the "practical indicia" of a submarket set forth in *Brown Shoe*. It is classified as a separate industry by the Office of Budget and Management (GX 29, p. 612), and the industry has its own trade associations, labor

unions and trade publications (Kolbe Dep. 168-169). Coal is produced, processed, and distributed by means, methods and facilities that differ from the means, methods and facilities used for other fuels (Tr. 1388-1389, DX 150, DX 116, pp. 75-89). And the major coal deposits are also located in different areas from the principal locations of other fuels (DX 150, p. 55). Coal is sold at a delivered price per BTU which is considerably lower than that for any other fuel except interruptible natural gas, which is available only on a seasonal basis (GX 35, GX 36, GX 37). Coal's price advantage makes it the primary fuel source for consumers such as electrical utilities whose fuel costs represent a significant part of their cost of doing business. Coal contributed 90 to 93 percent of the BTU's of heat consumed by steam electric utility plants in the Eastern Interior Coal Province Sales Area in each of the years 1960 through 1967 (GX 31) and 74.1 percent of the BTU's consumed by cement plants in that area during 1967 (GX 32).

The district court's failure to recognize coal as a relevant line of commerce stemmed from its misunderstanding of this Court's decision in *United States* v. *Continental Can Co.*, 378 U.S. 441. While the Court there did hold that evidence of competition between glass and metal containers indicates the existence of a "line of commerce" encompassing both, it by no means held that they together constituted the only "line of commerce" relevant for Section 7 purposes. On the contrary, the Court specifically recognized that each might constitute a separate line of

commerce: "Glass and metal containers were recognized to be two separate lines of commerce. But given the areas of effective competition between these two lines, there is necessarily implied one or more other lines of commerce embracing both industries" (378 U.S. at 456-457). Moreover, *Continental Can's* holding itself evidences the continuing vitality of the submarket concept, since the decisive line of commerce there was recognized to be a subdivision of a broader "container" market. 378 U.S. at 457-458.*

2. Having rejected coal, and opted for the "energy market" as the exclusively relevant product market, the trial court proceeded to adopt a patchwork of geographic markets, which, far from being defined by the marketing of "energy," were defined by alleged distribution patterns of various subspecies of coal.

The defendants proposed ten geographic markets, which the court adopted out of context. The defendants' proposed markets were not designed to illustrate how "energy" is distributed in the midwest, or even primarily to show how coal is distributed, but rather to attempt to prove that Freeman and UEC did not compete. Quite apart from the failure of defendants' markets to explain away the fact that UEC and Freeman sold about half of their produc-

---

* See also *Reynolds Metals Co.* v *Federal Trade Commission*, 309 F.2d 223 (C.A. D.C.), in which the court of appeals stated, in analyzing the *Brown Shoe* decision, that distinct submarkets "may henceforth be the focal point of administrative and judicial inquiry under Section 7." *Id.* at 226.

tion to the same facilities of the same customers, they were not geographic coal markets.

Defendants' proposed geographic markets were based on the utility and non-utility sales areas for the four Freight Rate Districts in which Freeman's and UEC's mines were located at the time of trial.[10] Defendants purported to show that there was no competitive overlap between the sales areas of the districts in which Freeman's mines were located and of those in which UEC's mines were located. In order to reach this result, it was necessary for defendants to exclude all sales to Chicago, all sales to Commonwealth Edison and all sales of coal dust. This resulted in the exclusion of more than half of the production from these Freight Rate Districts—26.3 million tons out of 50.3 million tons (DX 55).

Defendants attempted to justify these enormous exclusions on the basis of differences in product. They contended that Commonwealth Edison[11] and Chicago sales can be disregarded because these customers will not in the future be buying coal from the Freight Rate Districts in which UEC's mines are located[12]

---

[10] UEC's mines were located in the Fulton-Peoria and Belleville Freight Rate Districts; Freeman's mines were located in the Springfield and Southern Illinois districts.

[11] Thus, by accepting the defendants' markets for a purpose for which they were not intended, the district court has concluded that the Commonwealth Edison Company is a "section of the country" for Section 7 purposes.

[12] Defendants also contended that Commonwealth Edison should be segregated because of its unique consumption patterns and its commitment to nuclear energy (see App. 58a).

because the coal there has a high sulphur content,[13] and they contended further that dust sales can be disregarded because coal dust and coal screenings are not competitive products.

These contentions are refuted by the record. Commonwealth Edison must continue to use coal of high sulphur content to meet its great fuel needs (see Tr. 1996); the record shows Chicago customers can comply with air pollution regulations by mixing low sulphur coal with high sulphur coal (Stanley Dep. 24-25); and many utilities have facilities capable of substituting regular coal screenings for coal dust.[14]

By contrast, the government's proposed markets were designed to identify an economically significant area in which the effects of the merger will be felt. *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 357. Approximately 82 percent of the coal produced in the Eastern Interior Coal Province was sold in the Eastern Interior Coal Province Sales Area in 1967 (GX 52) and more than 99 percent of the coal consumed by electric utilities in the area was produced in Eastern Interior Coal Province mines (GX 61). In the same year Freeman and UEC

---

[13] Thus, in adopting "energy" as the product market while adopting these narrow geographic markets, the district court held that, while various other forms of energy compete with coal, different kinds of coal do not compete with each other.

[14] The district court itself recognized the competition of coal dust and coal screenings. It noted that "special equipment for the handling and burning of dust has been developed and installed at certain generating facilities which permits the use by them of limited amounts of dust along with regular coal screenings as boiler fuels" (App. 6a, n.6).

sold 93.3 percent and 97.6 percent, respectively, of their production in this area (GX 52). Illinois is also a relevant market. In 1967 Illinois coal customers purchased 82 percent of their requirements from Illinois mines (GX 51). See *United States* v. *Pabst Brewing Company*, 384 U.S. 546, 549.

3. A horizontal merger is particularly likely to result in a substantial lessening of competition because it produces a direct and immediate increase in the level of concentration in a market. This Court, accordingly, has consistently measured a challenged horizontal combination's effect upon market structure and has attached primary importance to that factor. The Court stated in *Brown Shoe Co., supra*, that statistics "reflecting the shares of the market controlled by the industry leaders and the parties to the merger are, of course, the primary index of market power * * *." 370 U.S. at 322, n. 38. In *United States* v. *Philadelphia National Bank, supra*, the Court concluded that in some circumstances the market shares of the merging parties is more than a "primary index" of market power and the combined market share alone may demonstrate that a merger "is so inherently likely to lessen competition substantially that it must be enjoined in the absence of evidence clearly showing that the merger is not likely to have such anticompetitive effects." 374 U.S. at 363. The Court declined to specify the minimum combined market share which will establish *prima facie* illegality, but concluded that the merging banks' combined share in excess of 30 percent was clearly

sufficient. In *United States* v. *Continental Can Co.*, *supra*, the Court reversed a dismissal at the end of the government's case where the combined firms accounted for 25 percent of the appropriate market.

The Court concluded in *United States* v. *Von's Grocery Co.*, 384 U.S. 270, and *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, that mergers involving considerably smaller combined market shares are likely to result in a substantial lessening of competition if the merger occurs in a market which has experienced a rapid increase in the level of concentration. In *Von's Grocery*, the Court noted that the merger involved the combination of the third and sixth largest firms in the Los Angeles area to form the second largest firm with a combined market share of 7.5 percent, further noted that there had been a rapid increase in the level of concentration, and declared that "[t]hese facts alone are enough to cause us to conclude contrary to the District Court that the Von's-Shopping Bag merger did violate Section 7." 384 U.S. at 274. Mr. Justice White's concurring opinion in *Von's Grocery* emphasized that the degree of concentration within the market as measured by the market shares held by the leading companies must also be considered. 384 U.S. at 281. In *Pabst*, the merging firms accounted for 4.49 percent, 11.32 percent and 23.95 percent of the three proposed markets. The Court found on the basis of these market shares and the trend toward concentration that *prima facie* illegality had been established in all three markets. 384 U.S. at 551-552.

In view of the pronounced trend toward concentration in the Illinois and Eastern Interior Coal Province Sales Area markets and the leading position of the combined firms in those markets (*supra*, pp. 5-8), the Freeman-UEC combined shares in those markets—23.2 percent in Illinois and 12.4 percent in the Province in 1959 (*supra*, pp. 6, 7)—was clearly sufficient to require (in the absence evidence clearly showing the contrary) the conclusion that the combination "may * * * substantially * * * lessen competition * * *" (15 U.S.C. 18).

4. Notwithstanding this showing, the trial court held that "the Government's failure to show that a substantial lessening of competition resulted from the United Electric-Freeman combination is fatal to this divestiture action" (App. 60a). In reaching this conclusion the court committed at least two errors.[15] The court erred, as a matter of law, in assessing the competitive potential of an independent UEC, by looking at its actual and potential resources only as they stood after 11 years of control by its competitor, *i.e.*, by looking into whether, at the time of trial, it could survive, if divested. And, in any event, the

---

[15] The quoted language also raises the possibility that the court believed that the government's structural evidence did not even establish a *prima facie* case. This would clearly be error under *Philadelphia Bank, Von's Grocery Co.* and *Pabst Brewing Co., supra.* However, since the court rendered it's opinion after the close of trial, it cannot be said with certainty whether the court was speaking of the government's burden or of its view of all the evidence introduced by both sides. Our argument assumes the latter.

court erred in concluding that UEC is not now a potentially viable independent competitor.

Stating that "[t]he adequacy of crucial resources" is essential to a competitor (App. 63a), the court held: "The Government failed to come forward with any evidence that such reserves are *presently* available" (App. 63a) (emphasis in original). Similarly, the court ruled: "United Electric *has* neither the possibility of acquiring more nor the ability to develop [its own] deep coal reserves" (App. 65a) (emphasis added). Conversely, the court made no assessment of what UEC might have been able to do, had it remained independent in, and after, 1959.

This was legal error. It is true that Section 7 requires the court to consider, from the vantage point of the time of suit, whether the acquisition may substantially lessen competition (*United States* v. *duPont & Co.*, 353 U.S. 586, 596-598, 607), and that in some circumstances post-acquisition evidence may show that "the acquisition threatens to ripen into a prohibited effect" (*id.* at 597). But it is equally fundamental that Section 7 deals in potentialities, and that post-acquisition behavior must not be permitted to obscure the real competitive potentialities cut off by the acquisition. As the Court explained in *Federal Trade Commission* v. *Consolidated Foods Corp.*, 380 U.S. 592, 598:

> [T]he force of § 7 is still in probabilities, not in what later transpired. That must necessarily be the case, for once the two companies are united no one knows what the fate of the acquired

company and its competitors would have been but for the merger.

Consequently, the Court held, post-acquisition evidence is not to be "given conclusive weight or allowed to override all probabilities * * *" (*ibid.*).[16] It follows that the district court erred in the present case by assessing the relevant competitive effects solely on the basis of whether the acquired firm could survive *at the time of trial* as a competitive entity, without also (and more significantly) determining the competitive potential cut off by the acquisition.

But even assuming that it was proper for the court to consider UEC only as it was at the time of trial, the court clearly erred in finding that UEC could not then acquire the expertise to mine its deep reserves and would not be able economically to mine its uncommitted strip reserves. UEC began acquiring deep reserves in the Round Prairie Field in 1958 (Tr. 170-171, Dorrance Dep. 27), the year before Material Service assumed control of UEC. Defendants' coal reserves expert testified that coal companies do not acquire coal reserves unless they intend to mine them (Organ Dep. 151). This was not an unrealistic expectation. Humble Oil made a *de novo* entry into deep mining in Illinois after 1964. It constructed a deep mine at a cost of between $10 million and $20 million (excluding the

[16] See, also, *United States* v. *Continental Can Co., supra*, 378 U.S. at 463; *United States* v. *Penn-Olin Chemical Co.*, 378 U.S. 158, 170, 177; *Federal Trade Commission* v. *Procter & Gamble Co.*, 386 U.S. 568, 577.

cost of reserves), which is expected to produce 3,000,000 tons per year for 20 to 30 years, and it has contracted to sell coal to Illinois utilities (Stipulated Testimony of George H. Shipley). Ayrshire Collieries Coal Company also developed a deep mine after many years of operating exclusively as a strip mining company (Tr. 1867-1871).

A former UEC president with deep mining experience testified that, as of 1969, a deep mine with annual capacity of one million tons of production could be constructed at Round Prairie at a cost of 7 to 8 million dollars (Camicia Dep. 32-33, 193-194). A company with $10.7 million in working capital, a net worth of $26.9 million and *no* long-term debt obviously could obtain the funds to undertake such an investment and to hire the experts it might need. Accordingly, the court's apparent finding that an independent UEC would not be capable of entering deep mining and continuing as a major competitor in the relevant coal market is clearly erroneous on this record.

The district court's similar finding (App. 63a) that existing strip reserves, including the UEC reserves at Industry Field, will not become economically feasible to mine before the present UEC mines are exhausted, is also erroneous. The depths and stripping ratios at which coal can be economically stripped have continuously increased over the years (Nugent Dep. 373, 374; Tr. 93, 1866; Organ Dep. 111-112, 136-137). And a former UEC president testified in his 1968 deposition that the Industry Field will be mined when

commercially mineable coal in Fulton County is exhausted in 10 or 12 years (Nugent Dep. 343). Exhaustion of the last of UEC's present mines is not expected to occur until sometime in the 1980's (see DX 60-C).

Moreover, if UEC does not now have adequate reserves, or the prospect of acquiring more, it is because of management policies imposed on it *after* the acquisition. After 1959 UEC management did not acquire strip reserves except in the area of existing mines although other companies were acquiring Illinois strip reserves for future mining during the 1960's (Tr. 1667-1668, 1867-1869, 1883-1885).

It is thus apparent that if UEC had remained independent, it would have had the means and the incentive to acquire any additional reserves it may need to remain in the strip mining business and to undertake the mining of its deep coal reserves. Accordingly, the district court should have found that the 1959 combination did eliminate an effective competitor and should have fashioned proper relief to restore UEC to the competitive position it would have occupied if the combination had not occurred. *Utah Commission* v. *El Paso Natural Gas Co.*, 395 U.S. 464, 470.

CONCLUSION

Probable jurisdiction should be noted.

Respectfully submitted.

ERWIN N. GRISWOLD,
Solicitor General.

SEPTEMBER 1972.

APPENDIX A

UNITED STATES DISTRICT COURT
NORTHERN DISTRICT OF ILLINOIS
EASTERN DIVISION

No. 67 C 1632

[Filed Apr. 13, 1972]

UNITED STATES OF AMERICA, PLAINTIFF.

vs.

GENERAL DYNAMICS CORPORATION; THE UNITED ELECTRIC COAL COMPANIES, AND FREEMAN COAL MINING CORPORATION, DEFENDANTS.

DECISION ON THE MERITS

In this antitrust divestiture action, the Government attacks the 1966 merger of General Dynamics Corporation with The United Electric Coal Companies (United Electric). The Government bases its complaint upon the contention that the General Dynamics-United Electric merger violated Section 7 of the Clayton Act. 15 U.S.C. § 18.[1] The juris-

[1] Section 7 of the Clayton Act provides, in pertinent part, as follows:

"No corporation shall acquire, directly or indirectly, the whole or any part of the stock or . . . assets of one or more corporations engaged in commerce, where in any line of commerce in any section of the country, the effect of such acquisition . . . may be substantially to lessen competition, or to tend to create a monopoly."

diction of the court pursuant to 15 U.S.C. § 25 is undisputed. After a trial on the merits and evaluation of the massive quantity of evidence submitted by the parties,[1] this court is of the opinion that judgment should be rendered for the defendants.

I. THE DEFENDANTS

General Dynamics

The defendant General Dynamics Corporation (General Dynamics) is a Delaware corporation with its principal executive offices located in New York. General Dynamics is a large, diversified corporation selling to government services and agencies, as well as to industrial and commercial customers. Over 85 per cent of General Dynamics' annual sales are to government services and agencies, and principally consist of aircraft, space, communications, and marine products. General Dynamics' sales to industrial and commercial consumers include commercial communication equipment, building materials, lime, machinery, and the subject of this litigation: coal.

The evidence at trial reveals that General Dynamics acquired Material Service Corporation (Material Service) in 1959, as part of its attempt to diversify into commercial, nondefense business. Material Service was at that time a midwest producer and sup-

[1] The record in this case consists of more than 7,500 pages of trial transcript and deposition testimony, and more than 800 trial and deposition exhibits, containing in excess of 10,000 pages.

plier of building materials, concrete, coal and limestone; it owned all of the stock of the defendant Freeman Coal Mining Corporation (Freeman) and 34 per cent of the outstanding stock of the defendant United Electric.

At the time of the General Dynamics-Material Service merger, General Dynamics was also seeking diversification through development of commercial products stemming from such subsidiary programs as the Convair 880/990 jet transport; Canadair's commercial turbo-prop CL-44 and CL-540 aircraft; General Atomic's nuclear research maritime and power reactors; Liquid Carbonic's industrial gases; and Stromberg-Carlson's telephone and high fidelity sound equipment. By the time of trial, however, these diversification ventures had been discontinued or sold, with the exception of Stromberg-Carlson's communication equipment business. In the early 1960's, General Dynamic's Convair Division phased out its commercial jet transport production program. During 1967, General Dynamics sold General Atomic to Gulf Oil Corporation, and in 1969, as a result of an adverse decision in *United States* v. *General Dynamics Corp.*, 258 F.Supp. 36 (S.D.N.Y. 1966), it sold Liquid Carbonic to Houston Natural Gas Corporation.

General Dynamics is the fifth largest coal miner among commercial producers. Through its two coal subsidiaries, Freeman and United Electric, General Dynamics had combined sales of nearly 15 million tons in 1967. The evidence did not disclose that

General Dynamics presently engages in any aspect of either the electric utility or fuel industries other than coal production.

Freeman Coal Mining Corporation

The defendant Freeman is an Illinois corporation headquartered in Chicago, Illinois. Freeman was acquired by the Burton Coal Company in 1922, the same year it acquired its first mine, the Bobby Dick, located in Williamson County, Illinois. Throughout its history, Freeman's mining operations have been centered in Jefferson, Franklin and Williamson counties in the Southern Illinois Freight Rate District.[3] In addition, it has operated the Crown Mine in the Springfield Freight Rate District located in central Illinois.

Material Service acquired Freeman and the assets of Burton Coal Company, both of which were in bankruptcy, in 1942. Empire Building Corporation which, like Material Service, was controlled by the Henry Crown family, acquired the stock of the Chicago, Wilmington & Franklin Coal Company (CW&F) in 1954. After the acquisition of CW&F stock by Empire Building Corporation, Freeman operated the mines of CW&F and sold the coal which they produced. Thus from 1955 forward, CW&F and Freeman were, for all practical purposes, one coal company.

---

[3] The Interstate Commerce Commision has designated various coal producing areas within Illinois, Indiana and western Kentucky as Freight Rate Districts. See, *e.g.*, *Ayrshire Collieries Corp.* v. *United States*, 335 U.S. 573 (1949).

Among 37 coal producers in the midwest, Freeman ranks eighth in terms of coal reserves in Illinois, Indiana and western Kentucky, but controls less than four per cent of the total midwest reserves controlled by these companies in 1968. Of the nine "leading" Illinois coal producers[4] reporting their coal reserves, Freeman ranks sixth in reserve holdings. Of the 11 "leading" producers in the three-state area, Freeman ranks seventh in reserve holdings. Freeman controls 6.5 per cent of the more than 2 billion tons of coal reserves dedicated to existing mines in Illinois, Indiana and western Kentucky as of 1968.

While Freeman's reserves in central Illinois are of relatively low BTU value[5] and have a sulphur content of over three per cent, substantially all of the reserves and production at Freeman's Orient mines are high quality, high BTU coal with a sulphur content of less than 2.5 per cent, and ranging as low as one per cent. Approximately one-half of Freeman's other reserves in Williamson and Jefferson counties have a sulphur content of less than 1.5 per cent.

Approximately eight per cent of Freeman's production is sold for metallurgical purposes, and an addi-

---

[4] The Government in its statistical exhibits has designated certain midwest coal producers as "leading producers." *See, e.g.*, Government Exhibits 79 and 85.

[5] Coal, gas, oil and nuclear energy produce heat, measured in terms of BTU's (British Thermal Units).

tional 10 to 11 per cent is sold as dust.* All of Freeman's mines are deep shaft operations and, aside from its relationship with United Electric, Freeman does not appear to have ever operated any strip mines and apparently possesses neither experience nor expertise in strip mining. None of Freeman's mines or coal reserves are located in a Freight Rate District in which United Electric operates a mine or controls reserves.

The United Electric Coal Companies

The defendant United Electric was formed in 1919 as a consolidation of several coal properties located in the vicinity of Danville, Illinois. United Electric presently operates only the following four strip or open pit mines, all of which are in Illinois: the Cuba Mine located in Fulton County and opened in the early 1920's; the Fidelity Mine located in Perry County and opened in 1928; the Buckheart Mine located in Fulton County and opened in 1937, and the Banner Mine located in Fulton and Peoria counties and opened in 1960. In addition, United Electric has operated the following strip mines for the periods of time indicated: the Freeburg Mine located in St.

---

* The trial testimony indicates that dust is a by-product which occurs during the preparation of metallurgical coal. In the past, it was thrown away on "gob piles" at the mines. In more recent years, however, special equipment for the handling and burning of dust has been developed and installed at certain generating facilities which permits the use by them of limited amounts of dust along with regular coal screenings as boiler fuels. Dust is sold at a price under its cost of production.

Clair County, Illinois, was reopened in 1936, having been idle since 1933, and was closed in 1949; the Solar Mine located in Schuyler County, Illinois, was opened in 1945 and was closed in 1949; the Buffalo Creek Mine located near Madisonville, Kentucky, was opened in 1947 and was closed in 1959; the Skyline Mine located in Breathitt County, Kentucky, was opened in 1952 and was closed in 1956; and, finally, the Mary Moore Mine located in Vermillion County, Illinois, was opened in 1955 and was closed in 1965 upon the exhaustion of strippable reserves. United Electric also had a small deep coal mine in the 1920's and an underground mining operation at its Buffalo Creek Mine from June of 1952 until 1954. The evidence indicates that although United Electric was the largest strip coal mining company in Illinois in 1948, during the succeeding 20 years it opened only two new mines in the midwest (Banner and Mary Moore) and closed four mines (Solar, Freeburg, Buffalo Creek, and Mary Moore). Furthermore, it was shown at trial that the Cuba Mine was likely to close in the immediate future, while the Banner Mine would be exhausted in approximately five years.

Ownership and management of United Electric remained essentially the same from the late 1930's until 1954, when Material Service acquired 10 per cent of United Electric's stock. This acquisition was disclosed that year to both the Government and United Electric's stockholders. During the course of the next few years, Material Service increased its ownership in United Electric; by 1959, Material

Service controlled more than one-third of United Electric's outstanding stock. That year Material Service (and Freeman, its wholly-owned coal subsidiary) requested and received representation on United Electric's Board of Directors. As a result, Frank Nugent, President of Freeman, was made Chairman of United Electric's Executive Committee.

With the affiliation of Freeman and United Electric thus formalized in 1959, common control of the two coal companies was achieved.[1] This development was immediately disclosed to the public, as well as to competitors and customers of both Freeman and United Electric. Within months, Material Service was itself acquired by General Dynamics. An investigation by the Antitrust Division of the Department of Justice ensued, during which the Government was furnished information with respect to the stock ownership of Freeman and United Electric. No further action was taken by the Government.

During the early 1960's, General Dynamics continued to purchase United Electric stock, and, by 1966, immediately prior to its tender offer for the balance of United Electric's outstanding shares, General Dynamics held 66.15 per cent of the outstanding shares of United Electric's stock. In addition, throughout this period, the Material Service Profit Sharing Trust owned approximately 6.8 per cent of the outstanding stock of United Electric. General Dy-

[1] The evidence shows that United Electric had earlier made unsuccessful attempts to merge with, or to acquire, other Illinois coal producers.

namic's control of United Electric was continually disclosed to the public throughout the 1960's.

At the Board Meeting of General Dynamics on September 30, 1966, the directors authorized a tender offer to purchase the remaining outstanding shares of United Electric. That tender offer was successful: as of December, 1966, General Dynamics had acquired at least 90 per cent of the outstanding shares of United Electric stock, and shortly thereafter United Electric became a wholly-owned subsidiary of General Dynamics. The Government then filed this action on September 22, 1967, challenging the legality of the United Electric-General Dynamics affiliation under Section 7 of the Clayton Act.

The four operating United Electric mines (Cuba, Buckheart, Banner, and Fidelity) produced 5,750,000 tons of coal in 1967. As of December 31, 1969, United Electric's midwest coal reserves were down to approximately 118,000,000 tons.* Only 52,000,000 tons, consisting of Illinois strip reserves dedicated to United Electric's four existing mines, were shown at trial to be economically mineable. *Significantly, all but 4 million tons of the economically recoverable coal reserves of United Electric have been sold under long term contracts.* The balance of United Electric's coal reserves consists essentially of strip reserves at the Industry Field in McDonough and Schuyler counties in Illinois, and undeveloped deep reserves in the

* United Electric also controls certain coal deposits located in Colorado and Oklahoma, which are not in issue in this litigation.

Round Prairie Field in the Belleville Freight Rate District.

Among 37 coal producers in Illinois, Indiana, and western Kentucky, United Electric ranks eleventh in coal reserves, with less than one per cent of the total midwest reserves controlled by these companies in 1968. Of the nine "leading" Illinois producers[9] that reported their reserves, United Electric ranked eighth in reserve holdings. Of the 11 "leading" producers in the three-state area, United Electric ranked tenth in reserve holdings. Of the more than 2 billion tons of coal reserves dedicated to existing mines in Illinois, Indiana and western Kentucky, United Electric controlled 52,033,304 tons (of which only 4 million tons were contractually uncommitted) or approximately 2.5 per cent.

In contrast with Freeman, all of United Electric's production and coal reserves have an average sulphur content greater than 2.5 per cent. Furthermore, United Electric produces virtually no metallurgical coal. Combining statistically the reserves and production of United Electric and Freeman the result is as follows: The two companies together control 4.81 per cent of the total coal reserves in Illinois, Indiana and western Kentucky,[10] and account for 10.9 per cent of the area's production, *a more than 10 per cent decrease in the combination's percentage of such production since 1959.*

---

[9] See n. 4, *supra.*

[10] If United Electric's unmineable reserves are excluded, the per cent of coal reserves controlled by these two companies would aproximate 4.25 per cent.

II. BACKGROUND OF THE COAL INDUSTRY

Coal mining today is undergoing a period of rapid and pervasive change. Major readjustment in the structure and patterns of coal production and distribution has been required, and continues to be required."

Changes in the Demand for Coal

In 1920, coal accounted for 78.4 per cent of the energy resources consumed in this country. With the exception of the years during World War II, coal's share of the energy market declined steadily thereafter, and by 1968 represented only 21.4 per cent of this nation's energy resources. Since World War II, coal has been a decreasingly effective competitor for a number of uses and has been unable to maintain its position as a dominant fuel. Coal consumption in the United States declined from 441 million tons in 1947 to 277 million tons by 1954, primarily because coal lost its railroad and home heating markets to oil and gas. There is no longer a railroad market for coal, and since World War II the use of coal for space heating has declined 80 per cent or more. Furthermore, its use in the industrial market has failed to keep pace with the growth of in-

---

" As long ago as 1955, the president of the Chicago, Wilmington and Franklin Coal Company, a midwestern coal producer, had commented that "[t]he coal mining industry has run into a series of evolutionary changes which have caused a shrinkage in demand for its product and have brought severely competitive conditions." Defendants' Exhibit 48.

dustry during this period. The evidence clearly shows that coal's decline in these markets will continue as additional residential and industrial consumers convert to oil and gas.[12] The net result of these losses has been a diminished position for coal in the overall energy resource consumption pattern. Coal consumption in 1967 and 1968 was less than in 1947 and 1948. These national trends and patterns are paralleled in the midwest.

Emergence of Utility Demand as the Principal Market for Coal

As a result of market losses to other forms of energy, the utility market has become the mainstay of coal production, although the use of coal has not kept pace with the growth of utility output. In the utility market, coal also faces competition from other sources of energy, including not only natural gas, oil, and nuclear fuel, but also such emerging competitors as pumped storage[13] and geothermal energy.[14] The

---

[12] As one retail coal dealer in Chicago expresed it: "We feel that the retail coal industry, as an industry, if you can call it that, has a life of only about five years. . . . I think you could compare it to the ice business." Peterson Deposition, p. 14.

[13] At a pumped storage facility, water is pumped into an elevated reservoir by energy generated at the most economical base-load station during off-peak hours. During the periods of peak demand, the cycle is reversed and the water runs down from the facility through hydroelectric turbines to generate power.

[14] In a geothermal system, underground steam is tapped directly to provide power to drive turbine generators.

evidence clearly indicates that coal's present dominant position in the utility industry will suffer increasing erosion, and nuclear energy may eventually displace coal entirely as an energy source for midwest utilities. Ernest Tremmel, Director of the Division of Industrial Participation of the United States Atomic Energy Commission, testified that, in the long term, electricity could be generated at the lowest cost by a utility system combining nuclear and pumped storage facilities, together with gas turbine peaking units.

More immediately, air pollution abatement regulations will have an adverse impact on coal during the next 10 to 20 years due to their effect on interfuel competition and consumption patterns of coal. A number of witnesses testified that there is and will continue to be a tendency to turn to other fuels, such as gas, oil, and nuclear energy, as a means of coping with air pollution abatement regulations. The net effect of this trend will be an increase in the consumption of these fuels at the expense of coal. In their report to the Federal Power Commission, the West Central Region Advisory Committee [15] predicted that in the midwest, coal's share of the electric utility market would decline from 72.2 per cent in 1966 to 22.2 per cent by 1990, and nuclear energy's share will increase from one per cent to 69.7 per cent in the same period. The report specifically stated that:

---

[15] This committee includes executives of such major midwest utilities as Commonwealth Edison, Northern States Power, Wisconsin Electric Power, Union Electric Company and Illinois Power Company, among others.

> "During the period 1970-1990, electric generation will be dependent upon five basic forms of energy—coal, gas, oil, hydro, and nuclear. . . . Coal, however, will be faced with continuing pressures from other forms of energy, and based on present trends the most significant competition will be from nuclear energy." Defendants' Exhibit 257, p. II-9.

Thus, the competitive situation within the energy market as a whole is already more fluid than it has ever been before and will become increasingly so in the future. Dr. Bruce C. Netschert, an expert in energy economics, testified that:

> "Competition is today more severe, more keen, among the fuels and between the fuels and between the fuels and electricity, and . . . intersubstitutability is also greater than it has been before. . . . [B]oth this competition and this intersubstitutability is likely to increase in the future. The choice facing the consumer is wider than ever before and will become still wider. Netschert Deposition, p. 53.

Changes in the Production of Coal

The fact that coal continues to be one of the suppliers of the energy requirements of the electric utilities reflects the success of coal producers in delivering coal at a low cost per BTU.[16] That coal producers

[16] The report of the West Central Advisory Committee to the Federal Power Commission, discussed *supra*, also stated that "[d]uring the past twenty years the coal industry has contributed a great deal to the stability of fuel prices." Defendants' Exhibit 257, p. II-9.

have been able to do this, despite sharply rising costs, reflects the technological revolution that has led to enormous increases in productivity, and to the ability to negotiate bulk shipment and unit train freight rates. The testimony and exhibits indicate that both coal prices and coal rail rates have increased far less than other prices in the economy.

Since 1947, despite a substantial rise in the level of the wholesale price index and labor costs, the delivered price of energy from coal has remained relatively stable. In fact, allowing for inflation, the price of coal at the mine mouth today is actually less than it was at the beginning of the postwar period. Defendants' Exhibit 85, Tables XX, XXI, XXIV. Since World War II, wage costs and fringe benefits have increased markedly in the coal industry. There has been a virtual revolution in mining technology, with the introduction of wholly new techniques, significant improvement in old techniques and a substantial increase in scale. The evidence shows that the effect of these technological changes has been to increase productivity (as measured in output per man-day) sufficiently to enable the f.o.b. mine price of coal to be kept competitive and relatively stable in the face of general inflation in wholesale prices. *E.g.*, Defendants' Exhibit 85, p. 4. Since World War II, the increased competitive pressure on coal in the utility market has led to increased pressure on the railroads to offer lower rates and has generated major technological innovations in railroad transportation, such as the unit train, which have permitted lower freight rates.

Changes in the Structure of the Coal Industry

The effect of the changes since World War II in the patterns of coal consumption and marketing, in labor costs, in mining technology, in productivity, in coal preparation procedures and in transportation costs has been to enhance the economies of scale production and to greatly increase capital requirements. This, in turn, has led to an increase in the size of mines. The parties stipulated that 83 percent of the coal produced in 1967 in Illinois, Indiana and western Kentucky, for example, was produced at mines with annual production exceeding 1 million tons; and 49 per cent from mines producing more than 2 million tons a year. Moreover, of the 36 mines placed in operation or announced in Illinois, Indiana and western Kentucky since 1958, none was smaller than 500,000 tons annual capacity, 29 were of a 1,200,000 tons annual production size or greater, and 20 produced or will produce 2 million tons or more per year. Defendants' Exhibit 87, Table 4. Clearly, mines of this size can only be operated by large coal producers. A 2 million ton strip mine, for example, would cost between $12.7 million and $23.5 million to construct, depending upon the overburden ratio,[17] and would necessitate 40 million tons of coal reserves. Defendants' Exhibit 87, Table 5a.

There are fundamental differences between the mines of the eleven "leading" coal producers (as

[17] The overburden ratio expresses the amount of overburden (cubic yards) which must be removed to uncover a ton of coal.

designated by the Government) in Illinois, Indiana and western Kentucky and the mines of the approximately 26 other coal producers. The latter are typically located in the West Kentucky or Southern Illinois Freight Rate Districts; have extremely limited coal reserves; produce small annual tonnages; operate only under very favorable strip mining conditions or are shallow deep mines; do not have substantial processing facilities; have limited transportation facilities; and usually sell through agents or dealers rather than directly to customers. These smaller producers rarely sell under long-term contracts with utilities. They do not and cannot constitute a substantial supply source for the energy requirements of electric utilities. As the testimony of a number of witnesses indicated, small producers are, for all practical purposes, in a "different business." [18]

The increasing predominance of the electrical utilities as purchasers of steam coal, the increase in the designed capacity of new electric generation units, and utilities' insistence on a large, reliable, and low-price source of fuel over the 20 or 30-year life of a generating facility, have led to the emergence and survival of coal producers with large reserves, developing large mines which are devoted to serving a smaller number of customers on long-term con-

tracts. The progressive disappearance of the small coal producers reflects the disappearance of the railroad market and the decline of the space heating market, the retail market and spot coal purchases by utilities.

Not only is this litigation devoid of any signs of anticompetitive performance and behavior in the coal industry, but rather the past performance of the industry suggests there has been intense competition among coal producers. The intense competition which midwest coal producers face is likely to increase even more in light of competition from nuclear energy and other alternative fuels, growing concern with air pollution, pressures from large, informed and capable buyers of coal, and the presence of a substantial number of viable coal competitors. From all of the evidence presented at trial, it appears that coal producers will be under continuing pressure to reduce costs and keep prices low if they are to continue to serve their last remaining large market for steam coal.

The Principal Market for Coal: The Utility Industry

Since 1946, a constantly increasing percentage of total coal production has gone to electric utilities as railroad, retail, and industrial markets have been lost to other fuels. See Defendants' Exhibit 85, Table I; Defendants' Exhibit 216. This trend was true in the midwest and will undoubtedly continue, according to the evidence presented by at least two knowledgable witnesses.[19] Thus, while some 70 per cent of

[19] Gallagher Deposition Exhibits 1-3; Steiner Deposition Exhibit 2, paragraph 2.

United Electric's 1967 sales were to electric utilities, by January 1, 1969, more than 82 per cent of United Electric's mineable reserves had been sold to electric utilities under long-term contracts. In 1967, approximately 75 per cent of the coal production in Illinois, Indiana and western Kentucky was shipped to electric utility generating stations. In each of the years 1965 through 1967, the largest coal customers in Illinois were steam electric utilities. It is undisputed that in 1967, 72 per cent and 89 per cent of the coal produced, respectively, in the Fulton-Peoria and Belleville Freight Rate Districts, where all of the mines of United Electric are located, was sold to electric utilities. 95 per cent and 71 per cent of the coal produced, respectively, in the Springfield and Southern Illinois Freight Rate Districts, where all of the mines of Freeman are located, was sold to electric utilities.

The evidence demonstrates that in considering whether a particular coal mine can compete for the business of an existing power plant, several factors must be weighed. These include the cost of coal at the mine, the location of the mine relative to the consumer's plant, transportation costs, the BTU content of the coal and the suitability of the physical and chemical properties of the coal produced by a given mine for the particular plant facility involved. In the case of a new utility plant, coal supply arrangements are almost always made prior to plant construction, since the facility's coal burning equipment will be specially designed to handle the type of coal

that is to be made available. Arrangements for transportation of the coal are also likely to be made in advance. As a result, the location and design of a plant are frequently determined by the coal supply arrangements that can be made.

Because of (1) the need to assure a supply of coal that satisfies the physical and chemical requirements of the equipment designed, (2) the complexities of administering multiple coal contracts, and (3) the development of large-scale transportation arrangements with their attendent economies, coal supply for large power plants is likely to be developed with relatively few producers. Indeed, many plants are supplied by only a single producer from a single mine opened specifically to serve that single facility. Such supply arrangements also exist in the case of mine-mouth generating plants where the adjacent mining property is expected to meet the lifetime requirements of the plant. In arranging for its coal supply, a utility will not only seek the lowest possible price per BTU of delivered coal, it will also seek assurance of the coal supplier's capability of providing the required quantities of coal over a long period of time. Utilities are therefore concerned about the reliability of the coal supplier and his past record of performance in satisfying contractual commitments. As one of the consumer witnesses emphasized, when a utility is arranging for the fuel supply for a modern generating station representing an investment of several hundred million dollars, it wants "to know that

the people you sign a contract with are able to produce on their end of it." [20]

The testimony also indicates that a utility consumer will weigh heavily its previous experience with potential suppliers and will carefully investigate the availability of adequate coal reserves within the supplier's control to satisfy the contractual commitments. The utility will seek independent geological verification of the existence and size of the coal reserve and the physical and chemical properties of the coal, as well as the producer's technological capabilities.[21] Since 1947, the average size of steam-electric generating plants, and units within those plants, has increased enormously. By 1966, the average size of new units being installed was almost as large as the combined total size of *all units* at existing plants. Defendants' Exhibit 86, Table following p. 9. The increasing size of electric power generating units and plants has been accompanied by an increase in the quantity of coal required at such facilities. A large, modern coal-fired generating unit of a thousand megawatt capacity would require, over its 30-year life, a total of 70 million tons, or approximately 2½ million tons of coal annually. A plant containing three such units (a size shown by the evidence likely to become commonplace) would,

[20] Tomey Transcript, pp. 336, 338; Gamble Transcript, p. 1263.

[21] See, *e.g.*, Defendants' Exhibit 86, p. 4; Hill Transcript, p. 1113; Gamble Transcript, p. 1263; Wood Transcript, pp. 678-79; Steele Transcript, pp. 996-997.

therefore, require committed mineable reserves of well over 200 million tons.

A 1000 megawatt plant may cost as much as 150 to 200 million dollars. This major investment can be jeopardized by a disruption in the supply of coal. Utilities are, therefore, concerned with assuring the supply of coal to such a plant over its life. In addition, utilities desire to establish in advance, as closely as possible, what fuel costs will be for the life of the plant. For these reasons, utilities typically arrange long-term contracts for all or at least a major portion of the total fuel requirements for the life of the plant. Illustratively, of the 74 million tons of coal purchased in 1967 by midwest utilities (other than municipal utilities) from mines in Illinois, Indiana and western Kentucky, *it is undisputed that approximately 76 per cent was purchased under contracts of five years or longer and 43 per cent was purchased under contracts of 15 years or longer duration.*

The long-term contractual commitments are not only required from the consumer's standpoint, but are also necessary from the viewpoint of the coal supplier.[22] Such commitments may require the development of new mining capacity. As a rule of thumb, a mine capable of producing a million tons of coal annually required, in 1969, an investment of between six to ten million dollars. Coal producers have been reluctant to invest in new mining capacity

---

[22] *Cf., Tampa Electric Co.* v. *Nashville Coal Co.*, 365 U.S. 320 (1961).

in the absence of long-term contractual commitments for the major portion of the mine's capacity. Furthermore, such long-term contractual commitments are often required before financing for the development of new capacity can be obtained by the producer.

This trend toward long-term contractual commitments to meet the total requirements of a particular electric power generating plant has tended to eliminate the spot market for coal. From time to time, a utility consumer may purchase small quantities of coal on the spot market and long-term contracts are often written to permit some flexibility in this regard. However, because utilities are increasingly arranging for bulk transportation of coal supply on a long-term basis, the opportunities for spot purchases are declining except in those cases in which small mines may be located in such proximity to make them capable of providing some relatively small deliveries at low cost. Moreover, the rail rate cost advantages of trainload deliveries compared to carload deliveries are such as to limit the desirability of such spot purchases. The growing practice by coal producers of expanding mine capacity only to meet long-term contractual commitments, and the gradual disappearance of the small truck mines has tended to limit the production capacity available for spot sales.

Competition for Utility Contracts

Because of the trend toward long-term contracts and away from spot purchasing, competition in the

electric utility market is not continuous in the sense that coal producers seek new orders from a given facility on a daily, monthly or even annual basis. Rather, competition tends to be a "one time thing." Once the initial coal contract is executed, competition to satisfy the coal requirements of a particular plant is effectively precluded for an extended period of time amounting to as much as 15 years or even the full life of the plant. This competition for long-term supply contracts, rather than competition for the sale of coal already produced, is of a kind in which a small producer or a producer without large reserves cannot effectively participate. This has led to the disappearance of small producers as active competitors in the utility market. Furthermore, the innovations in the coal industry that have made coal prices competitive with other forms of energy have created the need for large scale production and, thus, for large companies. Experts for both the Government and the defendants agreed that under these circumstances, increase in the size of coal mining companies and the concentration of more production in fewer mines, as well as more output of a given mine devoted to a particular source, have been economically inevitable.[23]

Correspondingly, mergers within the *utility industry* have both diminished the number of utility companies and increased the purchasing power of those surviving. Since 1955, there have been more than 50 mergers among midwestern public utilities. In

---

[23] Steiner Deposition, p. 176; Folsom Transcript, p. 2581.

1967, the four largest utility companies in the midwest, ranked by coal consumption, accounted for 53 per cent of the coal consumed by electric utilities in the states of Illinois, Indiana, Wisconsin, Iowa, Minnesota, Missouri, Kentucky, and Tennessee. Commonwealth Edison alone consumed approximately 33 per cent of the total coal production of the Freight Rate Districts in which Freeman and United Electric mines are located.

Fuel expenditures are a major component of a utility's operating costs.[24] In light of this, electric utilities typically regard fuel purchasing as a major executive responsibility and these buyers are characteristically sophisticated about the available alternatives. This circumstance provides another source of pressure on coal producers to seek to minimize costs and to keep coal prices low. George Gamble, a director of Union Electric Company, testified that coal contracts would characteristically be reviewed by that company's Executive Committee, as well as its Board of Directors. Gamble Transcript, p. 1264. Similarly, Elmer Hill, formerly of TVA, testified to the care taken in evaluating coal bids:

> "* * * [W]e had a staff of engineers. Each time we evaluated offers for supply to any of TVA's facilities, the reserves were checked, the equipment to be employed in supplying the coal was evaluated. With the engineering knowledge

[24] For example, in 1969, almost 50 per cent of Commonwealth Edison's operating expenses, excluding depreciation, were accounted for by fuel and power purchases. Defendants' Exhibit 90, p. 4.

and know-how as to mining, it could be reasonably determined what the cost for production would be." Hill Transcript, p. 1113.

The evidence further indicates that utilities possess and exercise the power to play coal producers against one another. As the president of one utility stated: "[W]e attempt to use whatever leverage we can to get the prices we can." Davis Transcript, p. 745. He explained that his company at the outset attempts to get a low-cost contract with one coal supplier, and then tries "to use that leverage on the other suppliers to obtain substantially the same price." Davis Transcript, p. 759. Finally, interfuel substitutability provides an additional bargaining advantage to utilities.

The bargaining power of utilities will increase even more in the years ahead, as midwest utilities pool their purchasing power by joining together to coordinate the planning, construction and utilization of generating and transmission facilities. See Defendants' Exhibits 232, 233; Defendants' Exhibit 257, Section IV and Appendices A, B, and C. As a result, and because they purchased coal in huge quantities, utilities have substantial market power as compared with coal producers. George Gamble described this power as follows:

> "Anytime that you are in a position to sign up over a period of 15 or 20 years for a block of business between $50 and $100 million, you've got power in the market, and [if] the coal producers can get hold of a large contract, which would run over a number of years, why, they

know what they can do, they know what they can afford to do in the shape of opening mines and buying machinery, and it's a very important thing to them.

"Consequently, there is a great economic power in the hands of the coal purchaser." Gamble Transcript, pp. 1264-1265.

Recognizing the validity of this analysis, the Government has conceded that utilities have at least equal bargaining power with coal producers in the midwest.

III. INTERFUEL COMPETITION

Energy resources consumed in the midwest include, among others, coal, natural gas, oil, nuclear energy and hydropower. Coal, gas, oil and nuclear energy produce heat, measured in terms of BTU's. Heat thus produced by any one of these energy resources can be used for various purposes, including the generation of electricity. Hydropower is also used to generate electricity. Coal, oil and gas are used to produce space and processing heat.

Coal, oil, gas and nuclear energy compete with one another in the utility, space heating and process heat markets.[28] Electricity (including that generated by hydropower and pumped storage) in turn competes with coal, oil, gas and nuclear energy for parts of these same markets. Coal's share of the energy market reached its peak in 1910. Since then, coal's position has been eroded in one market after another.

---

[28] Process heat is that used in the manufacture of chemicals, drugs, foods, glass, metals, cement and the like.

The railroads, once coal's mainstay, have been completely lost to oil through dieselization. The use of coal for space heating has already suffered a dramatic decline and is expected to disappear completely within five to ten years at the most.

Interfuel competition will continue to erode coal's share of the energy market as more and more industrial consumers convert from coal to gas or oil, and as these fuels, along with nuclear energy and the emerging technology of still other alternative power generation sources, further challenge coal's share of the fuel needs of electric utilities. Competition among fuels is a complex of economic, technological and political forces, and results from the ability and willingness of energy consumers, in light of these forces, to shift from one fuel or supplier to another. As a recent report of the Federal Trade Commission points out in a chapter to which the Government's rebuttal economist contributed,

> "• • • There is a high elasticity of substitution among coal, fuel, oil and natural gas as raw materials from which energy is produced. This is particularly marked in the case of electric utilities which have constructed generating stations so they can ultimately consume any of the three principal fuels." Folsom Transcript, p. 2494.

In determining the type of fuel to be used, a consumer reviews and evaluates a number of factors. Thus, the choice between competing fuels depends not only on delivered price, but on such matters as relative

thermal efficiencies and differences in capital costs of burning equipment as well. The costs of storing, handling, and in some instances, disposing of the fuel by-products or residue, for example, are economic factors which can make a low-cost fuel the most expensive fuel. These costs become a particularly important consideration in selecting a proper fuel in locations where land costs are high and in heavily congested areas. In some areas, operating considerations, such as air pollution control regulations, may require a premium priced fuel and foreclose consideration of others.

Energy consumers themselves testified at trial concerning the vigorous competition coal encounters from other fuels in the market place. As the representative of one midwest utility attested,

> "Certainly competition between coal suppliers is a big factor [in controlling the cost of coal], but I believe overriding this, which sets the overall competitive picture, is the alternate fuel competition. There is competition among all fuels as well as among coal suppliers." Wood Transcript, p. 661.

Coal producers, as well, confirmed the intense competition they face from suppliers of alternate fuels. See, *e.g.*, Beck Deposition, p. 8; King Deposition, p. 17; Stiehl Deposition, pp. 14-16.

Competition from Gas and Oil

The extensive competition which coal faces from gas and oil may be seen in the response of midwest

coal consumers to the questionnaire forwarded them under subpoena issued by this court. While the survey was directed solely to coal consumers, and thus takes no account of facilities consuming *only* other fuels, it reveals that, even among those midwest facilities (both utility and nonutility) which consume substantial amounts of coal, some 48 per cent have already installed the capability of consuming either gas or oil as well. Defendants' Exhibit 59, Table C. The subpoena questionnaire responses also demonstrate widespread actual usage of gas and oil as alternative fuels by these utility and nonutility facilities. Thus, nearly half of those facilities with an oil capability actually used oil during 1967, while of those facilities with a gas capability, 80 per cent actually consumed gas for six months of the year or more. Defendants' Exhibit 59, Tables C, D, E. Whether or not facilities actually consume gas or oil, however, their dual or triple fuel capability is a device used by them to play one energy source against another in keeping their fuel costs at a minimum.

Industrial Consumers

Coal has already lost its once dominant position with midwest industrial energy consumers. It has been estimated that 45 per cent of all such facilities in the midwest have already turned to gas, while another 20 per cent have switched to oil. Walker Deposition, pp. 11-12; Peterson Deposition, p. 10. The trend of industrial consumers away from coal is a continuing one. A recent fuel-use inquiry by the

Chicago Department of Environmental Control, for example, revealed that, of the nine responding manufacturing plants located within the City of Chicago which had earlier indicated in response to the court-ordered subpoena questionnaire that they were burning high sulphur coal, six have converted or will convert to the use of gas and oil exclusively. Of the remaining three manufacturing plants, one indicated that it would be burning two-thirds more gas and oil and one-third less coal than in 1967, while the other two were switching from the use of high sulphur coal produced in Illinois to low sulphur coal from other areas. Defendants' Exhibit 239.

The evidence also demonstrates that many other mid-western industrial and institutional consumers are converting from coal to other fuels. The facilities of American Distilling, Corn Products and Standard Brands in Pekin, Illinois; Hiram Walker and Keystone Steel in Peoria, Illinois; American Can in Green Bay, Wisconsin; Northwestern States Cement in Mason City, Iowa; McDonnell-Douglas and Proctor & Gamble in St. Louis, Missouri; American Maize in Roby, Indiana; the University of Chicago, the Metropolitan Sanitary District of Chicago, the City of Belleville, Belleville School District and St. Clair County, as well as the Government's own midwest facilities, for example, were all shown at trial to have recently discontinued the use of coal. Even the courthouse in which this litigation was tried was shown to have been converted recently from coal to a combination of gas and oil. The evidence revealed, more-

over, that the Government considers a careful economic appraisal of the relative merits of gas, oil, coal and other alternative fuels so important and common in its fuel purchasing decisions that the General Services Administration has prepared a standard form, "GSA Form 1289, Heating Fuel Economic Analysis," to assist in the process.

Utility Consumers

Oil and gas are also important competitors for the fuel requirements of midwest utilities. In some midwest states, for example, oil and gas already supply 50 per cent of the energy requirements of electrical utilities.[**] As a report to the Federal Power Commission by a group of midwest utility executives points out,

> Although coal is available in sufficient quantities in the West Central Region to supply the entire energy requirements of the electric utilities in this region, competition will determine the extent to which coal will penetrate each market." Defendants' Exhibit 257, p. II-9.

While the subpoena questionnaire was addressed only to the coal-fired facilities of midwest utilities, it revealed that, even with respect to these, 55 per cent were capable of burning gas and/or oil as al-

---

[**] Significantly, the only utility executive called to testify by the Government, Daric N. Miller, Manager of Electric Production, Kansas Power and Light Company, was from an area where 91 per cent of the fuel requirements of utilities are supplied by gas, eight per cent by oil and one per cent by coal. Miller Transcript, p. 1723; Defendants' Exhibit 138, p. 20.

ternatives to coal. Furthermore, 79 per cent of the utility facilities equipped to consume gas actually did so for six months or more during 1967. Installation of multi-fuel capability is not confined to small generating plants. This may be seen from the fact that the facilities with multi-fuel capability consumed close to 50 per cent of the coal shipped to large utility systems in the midwest.

Because of the growing concern with air pollution, oil and gas are rapidly increasing their share of the fuel business of midwest utilities. This includes even those utilities in close proximity to coal fields which have relied principally on coal to provide their generation in the past. Illinois' largest coal consumer, Commonwealth Edison, which 10 years ago had 58 coal-fired boilers in Chicago, today has less than a dozen.

Also leading to increased usage of gas and oil by midwest utilities is the fact that many utilities are increasing their capacity through installation of gas and oil peaking units. The capacity which these peaking stations represent has increased substantially in recent years. For example, the most recently announced gas turbine peaking station of Northern States Power Company has a capacity of 300,000 kilowatts. This exceeds the average size of the coal-fired base-load units being installed only five years ago. Such peaking units represent a significant portion of the new capacity being installed by utilities in the midwest."[27] Thus, the combined capacity of

[27] See Defendants' Exhibit 138, Table 6, pp. 73-86; Defendants' Exhibit 234, p. 4.

Northern States Power Company's gas and oil peaking stations (500,000 kilowatts) was shown to be equivalent to a coal-fired station consuming approximately one million tons of coal annually.

In the utility market, coal is also faced with a secondary level of competition from alternate fuels. The growth in demand for electricity which has occurred in recent years is not due to increased demand for illumination, where electricity is faced with virtually no competition. Rather, it is due to expansion of the use of electricity for home heating, air conditioning and appliances. These are areas where the electricity which coal generates encounters severe competition from oil and gas. Competition at the secondary level has become particularly intense in recent years with the development of the "total energy" concept where gas and oil are used not only to provide energy for heating, air conditioning and appliances, but for on-site generation of electricity as well.

Competition from Nuclear Energy

During the 1960's, the use of nuclear energy to generate electricity became a commercial reality, increasing still further the competition faced by coal. Thus, as of January, 1970, there were 16 nuclear plants in operation, 48 more under construction, and an additional 41 had been announced. Defendants' Exhibit 108. Midwest utilities have assumed a position of leadership in the development of nuclear-powered generating stations. Commonwealth Edison

was a pioneer in the field, and in 1960, opened the first privately financed nuclear generating station in the country. At the time of trial, Edison and TVA, the midwest's two largest coal consumers, accounted for approximately 20 per cent of the nation's private nuclear capacity on order, under construction or in service. TVA already has five nuclear units under construction which, when completed will represent approximately 25 per cent of its total generating capacity. At the close of 1970, Commonwealth Edison will have three nuclear units in operation. By 1973, the number will have more than doubled and some 40 per cent of its electric generating capacity will be nuclear. Beyond that, Edison already has plans for two more nuclear units in 1976 or 1977. Commonwealth Edison's spokesman at trial summed up the situation as follows:

> "Well, as far as Commonwealth Edison is concerned, we have sort of put our eggs in the nuclear basket. We believe that nuclear power is the best way to provide base load electric generation, and we intend to move in this direction." Corey Transcript, p. 1600.

Other utilities throughout the midwest are also committing themselves to nuclear energy. Northern States Power Company's first nuclear station became operational in 1971 and will be joined by two others in 1972 and 1974. Three Wisconsin utilities, Wisconsin Public Service Company, Wisconsin Power and Light Company, and Madison Gas and Electric Company have joined together to construct a large nu-

clear station which is scheduled to begin operations by 1972. Northern Indiana Public Service Company, Iowa Electric Light and Power Company, and Wisconsin Electric Power Company have also undertaken substantial commitments to nuclear energy. Dairyland Cooperative Company operates a small nuclear demonstration plant and plans to join with four other rural cooperatives in the construction of an additional nuclear station. Even those midwest utilities which do not presently employ nuclear energy emphasized at trial their continuing interest in, and financial support of, nuclear research and development, and the possibility that they might undertake nuclear commitments in the future. They stressed that even now they closely compare and evaluate the overall costs of nuclear and fossil fuel stations in all cases before making a decision as to which type of new generating capacity to install.

Even apart from environmental considerations, nuclear energy in the 1960's rapidly developed to the point where it was cost competitive with coal. In 1968, when TVA was planning a 3,300,000 kilowatt increase in its capacity, it carefully compared and evaluated both coal and nuclear fueled facilities and concluded that installation of a nuclear station would be more *economically* desirable.

The Atomic Energy Commission has considered nuclear energy to be a competitor of coal for the fuel requirements of electrical utilities, even those located in coal mining areas, since approximately 1965. The director of the Division of Industrial Participa-

tion of that commission testified at trial that fuel costs for a nuclear plant are "considerably cheaper than a fossil plant, and although the capital cost is higher, when you balance the total cost, this is why the utilities have gone to nuclear, because the total operating cost will tend to be lower in many cases due to the cheaper fuel cost." Tremmel Tr., p. 799. The Atomic Energy Commission estimated that by 1980, between 20 and 25 per cent of the nation's total generating capacity will be nuclear. Moreover, since these nuclear stations will be base-load facilities, i.e., operated continually, which are more fully utilized than older fossil units, the AEC has also predicted that between 30 and 35 per cent of the electricity actually generated in 1980 will be nuclear fueled.

The impact of increased installation of nuclear generating stations on the coal industry will be particularly severe in the midwest, where utility executives have reported to the Federal Power Commission that by 1990 nuclear facilities are anticipated to comprise 57 per cent of total capacity, with nuclear generation "expected to supply nearly 70 per cent of the region's energy requirements by that time." Defendants' Exhibit 257, p. S-5.

During the 1980's, when the so-called nuclear breeder reactor is expected to come into commercial use, two witnesses testified that coal's portion of the utilities' fuel business is likely to decrease further, with the possibility that it may ultimately be eliminated altogether.[28] The most significant advantage

[28] See Tremmel Tr., pp. 806-08; Netschert Dep., p. 38.

of the breeder reactor over present nuclear facilities is that the breeder reactor will actually make more fuel (which can be used or sold) than it consumes, thereby resulting in a negative fuel cost.

While there are substantial economies of scale in the construction and operation of nuclear facilities, this does not preclude the use of nuclear energy by the small utilities in the midwest. On the contrary, the evidence indicates that several smaller utilities have already undertaken the joint construction of large scale nuclear facilities.[29] Some midwest utilities have joined together in power pools such as MCPP (Mid-Continent Power Planners) (and MAIN (Mid-American Interpool Network) so that such joint nuclear projects can be more readily undertaken and efficiently coordinated in the future. Furthermore, the evidence also shows that companies with developed expertise and operating experience with nuclear energy, such as Commonwealth Edison, are available to lend technical assistance, and possibly supplies, to those undertaking nuclear commitments for the first time. Government's Exhibit 135. Moreover, the Atomic Energy Commission's witness also testified that quite apart from the utility market, nuclear energy has now developed to the point where its use as an alternative to coal for industrial facilities is already occurring, and can be expected to expand in the future as further technological advancements are made. Tremmel Tr., pp. 812-813.

---

[29] See Abrahamson Dep., pp. 19-20, 28; Morrison Dep., pp. 10-11; Moser Tr., pp. 1573-74; Steele Tr., p. 963.

Other Alternative Power Sources

Hydropower has long been a competitor of coal in the midwest. TVA, the midwest's largest coal consumer, originally used hydropower exclusively, and presently operates approximately 40 hydropower stations. Coal's competition in the midwest from this source of energy is expected to increase in the future in view of the steps being undertaken to integrate the huge hydroelectric potential in Canada with power developments in the midwest through power pooling arrangements.

Pumped storage hydroelectric projects will further increase the competitive pressure on coal. The evidence shows that there is a growing commitment to pumped storage power generation in the midwest. Pumped storage facilities tie in well with nuclear generation, and an Atomic Energy Commission spokesman predicted at trial that, in the long term, electricity could be generated at the lowest cost by a combination of nuclear energy, pumped storage, and gas peaking. Tremmel Tr., p. 810.

Another alternative to coal expected to add to interfuel competition in the future is the generation of electricity by geothermal steam. In this method of generation, underground steam is tapped directly to provide power to drive turbine generators. While the evidence discloses that installation of such facilities has thus far been confined to the west coast, some scientists estimate that by 1980 geothermal energy could be generating as much as 10 per cent of the total electrical output of the country. Defendants'

Exhibits 178, 179. More immediately, one witness testified that increasing geothermal capacity on the west coast will free gas, presently required there for the generation of electricity, for use in the midwest. Walker Dep., p. 23.

Multi-Energy Companies

An additional aspect of the competition coal faces from other fuels is the fact that coal producers such as United Electric frequently find themselves competing with much larger corporate enterprises which produce and sell a variety of energy sources and can thus fill all of a utility's fuel needs, regardless of kind. In the past six years, the oil industry has established itself as a major element in coal production, linking under common ownership, in many instances, the energy resources of coal, oil, gas, uranium, oil shale and tar sands. Four midwestern coal producers are owned by oil companies: Pittsburg and Midway Coal Co. (Gulf Oil), Consolidation Coal Co. (Continental Oil Co.), Island Creek Coal Co. (Occidental Petroleum Corp.) and Old Ben Coal Co. (Standard Oil of Ohio). In 1967, these companies accounted for more than 25 per cent of the coal produced in Illinois, Indiana and western Kentucky. Defendants' Exhibit 85, Table XXVIII; Government's Exhibit 85.

A fifth midwestern coal producer, Ayrshire Collieries Corp., had announced plans in early 1969 to merge with Ashland Oil & Refining Co. The merger discussions were terminated, however, and Ayrshire subsequently combined with American Metal Climax,

Inc., a major producer, fabricator and marketer of metals and minerals.

Humble Oil, the principal operating subsidiary of Standard Oil (New Jersey) is constructing a deep mine in Illinois capable of producing 3 million tons per year for 20 to 30 years. Humble has entered into a long-term contract to sell the mine's output to Commonwealth Edison. Humble controls deep coal reserves in the midwest estimated at 3 billion tons. In addition to its sale of oil, natural gas and coal, Humble also has extensive holdings of uranium.

Air Pollution Restrictions Intensify the Competition Coal Faces from Other Fuels

Without question, air pollution has become one of the nation's most difficult and urgent problems. The burning of coal results in the emission of particulate matter and sulphur oxides. These substances were the first two emissions designated as pollutants by the National Air Pollution Control Administration. Beginning in 1955, the United States Department of Health, Education and Welfare undertook a study of the effect of sulphur oxide and particulate emissions on health. That study led the Department to conclude that these pollutants represented a serious health hazard when they exceeded certain levels in the atmosphere. The Department subsequently published the results of its studies, stressing particularly what it believed to be the minimum air quality standards for safety with respect to these pollutants. Defendants' Exhibit 89, pp. 1-3.

As a result of widespread concern over the deleterious effects of these pollutants, tremendous public pressure developed for the enactment of pollution control legislation and regulations to curtail their emission into the atmosphere. Even before such restrictions became effective in many areas, demands were made by groups pressuring utilities to reduce their consumption of high-sulphur coal by substituting low-sulphur fuels.

While attention was focused at the outset on establishment of air pollution restrictions in major metropolitan areas, smaller communities have also begun to adopt air pollution regulations, and statewide regulation, where not already established, is anticipated. Concerning this trend, S. Smith Griswold, the defendant's expert witness on air pollution, testified as follows:

> "I believe that you are going to have statewide regulations similar to those in New Jersey, generally. If you don't have a state-wide regulation, you are going to have industries moving out into rural areas, the less urbanized areas, and subsequent dislocation of your industrial developments. I feel that this probably won't be acceptable from the standpoint of the area that is losing . . . . industry because of the severity of [air pollution] controls, plus the fact that you will see a wide range of local regulations . . . designed to keep areas, which are now clean, from being polluted." Griswold Dep., p. 240.[10]

[10] Mr. Griswold was formerly Assistant Director of the National Air Pollution Control Administration of the U.S. De-

In light of this regulatory trend, electric utilities and other large coal consumers will not be able to avoid air pollution restrictions by locating future facilities in rural areas. Indeed, much of the demand for state-wide controls is from residents of rural areas who do not wish to see their present relatively pollution-free environment deteriorate.

Abatement Techniques and Their Effect on Coal

The air pollution restrictions adopted throughout the midwest are substantially increasing the already intense competition which coal faces from other fuels. Only coal-burning leads to particulate emission. Similarly, while coal is the principal source of sulphur oxide pollution, gas and oil burning result in only negligible sulphur oxide emissions, and nuclear energy, of course, leads to none.

While electrostatic precipitators have been developed which are effective in controlling the particulate portion of the pollution emitted during the burning of coal, many consumers have found it more economical to convert to alternate fuels, or even to close down older facilities, rather than to install such devices in order to continue burning coal. This is because electrostatic precipitators are extremely high cost items of capital equipment. *The installation of such equipment can cost 2 million dollars or more at a single facility.* Because of this high cost, electrostatic precipitators are not practical for small coal-

---

partment of Health, Education and Welfare, and for eleven years he was the Air Pollution Control Officer of the Los Angeles County Air Pollution Control District.

burning facilities. This fact has been recognized by the National Air Pollution Control Administration.[21]

Even for utilities, however, the cost of electrostatic precipitator equipment often represents such a high investment that it is more economical to convert from coal to the use of oil or gas. At the 359,000 kilowatt R. S. Wallace Station of Central Illinois Light Company, for example, six of the 10 boilers were converted to gas because, as the president of the company testified at trial: "We cannot put electrostatic precipitators on these boilers economically." Davis Tr., pp. 690-91. Similarly, the president of Interstate Power Company testified that his utility expected to discontinue the burning of coal at its Fox Lake Station altogether. He explains that rather than put in a $1,400,000 electronic or electrostatic precipitator, "we will probably change over to burning oil." Steele Tr., pp. 935-36; see also Tomey Tr. p. 400-01.

Sulphur Oxide Control Devices

While equipment is at least available for reducing particulate emissions, the technology for controlling sulphur oxides, the other principal pollutant emitted during the combustion of coal, is still under development. The significance of air pollution restrictions on interfuel competition and the marketing of coal is underscored by the fact that three of the Government's five rebuttal witnesses were called to testify regarding sulphur oxide pollution control devices.

---

[21] Middleton Dep. Ex. 4, p. 3-19; see also Defendants' Ex. 160.

The most that two of these witnesses would say, however, was that they believed their respective companies would be able to develop commercially acceptable sulphur removal devices within five years. Craig Tr., p. 2068; Quig Tr., p. 2201. Both witnesses conceded that such devices would be quite costly, and that not a single utility had been persuaded to install one. One of these witnesses admitted that utilities "may very well turn towards the use of substitute fuels." Quig. Tr., pp. 2191, 2198.[22]

Daric N. Miller, an executive of Kansas Power and Light Company, testified with respect to his company's decision to place the nation's first order for a sulphur pollution control device designed by Combustion Engineering Company. Although he admitted that his company had encountered problems from the day it started up a smaller demonstration model of the device, Mr. Miller expressed the belief that the equipment would be reliable. Significantly, he stressed that his company's facility would not be operating on coal produced in Illinois, Indiana or western Kentucky.

This Combustion Engineering device has been tested on coal produced locally, however, by Union Electric Company at its Meramec Station near St. Louis. An executive from that company testified that the device was "not commercially operable" and was, in

---

[22] The Government has not seen fit to order any such devices in connection with the air pollution reduction program at its own facilities. Instead, it has converted to lower sulphur fuels. Griswold Dep. pp. 221-26; Griswold Dep. Exhibits 3, 4.

fact, "shut down for more design changes" when he left St. Louis to appear at trial. Tomey Tr., pp. 358, 400. The device was, in fact, operable for only one of the first nine months following its installation. Griswold Dep. 87. As Mr. Griswold summed up the situation:

> "They have corrosion problems, they have every kind of problem. They have got so many problems they didn't think about, that they haven't gotten around, in some cases, to figuring out what the answers are to things they planned to determine in this study." Griswold Dep. 87-88.

Recognizing the magnitude of the problems encountered with the Combustion Engineering system to date, other midwest utilities have rejected it. Combustion Engineering's representatives have publicly stated that "the system cannot be considered commercially acceptable at this time," and a Federal panel of air pollution technology experts has concluded that even the system's presently known problems "may require several years of additional study." Nicosin Dep. 49-50; Schotters Dep. 15; Griswold Dep. Ex. 5. A spokesman from Union Electric stated: "It's strictly an experimental unit." Tomey Tr. p. 400.

The evidence also shows that recently the National Air Pollution Control Administration of the United States Department of Health, Education and Welfare, commissioned a panel of technical experts to review the status of United States and foreign sulphur oxide

abatement and control processes in order to provide a basis for increased governmental and public understanding of the problems involved in these areas. On the basis of its independent evaluation of oral and written presentations by 46 companies, including the three from whom representatives were called by the Government at trial, the panel

> "firmly concluded that, *contrary to widely held belief, commercially proven technology for control of sulfur oxides from combustion processes does not exist.*" Defendants' Exhibit 254, p. 3 (emphasis in original).

It is impossible to predict precisely when effective sulphur oxide pollution control devices will become commercially available. While witnesses expressed the hope that it would be soon, it may be 10 years or more before such processes are refined to the point where they are generally available for installation on, or planning for, power plants burning coal. Griswold Dep. 54-55. Although there is a great deal of research taking place with respect to sulphur oxide pollution control technology, it is important to recognize that as long as 20 years may be required to go from paper studies through laboratory experiments, pilot plants, prototype plants, and commercial demonstration to commercial application. As the recent study of the National Air Pollution Control Administration emphasized,

> [e]fforts to force the broad-scale installation of unproven processes would be unwise; the operating risks are too great to justify such action, and there is a real danger that such efforts

would, in the end, delay effective SO_2 emission control." Defendants' Exhibit 254, p. 3.

Instead, the study urged a high level of government support for several years to encourage research, engineering, development, and demonstration of a variety of the more promising processes, as may be suited to specific local and regional conditions.

In any event, there will be a long delay between the time sulphur oxide control devices become commercially proven and their actual implementation. Five years or more of advance planning are required in the construction of a modern utility generating station. Government counsel asked one utility executive whether, for a new plant being designed to burn low-sulphur coal from Montana or Wyoming, his company would consider using high-sulphur coal produced locally if an effective sulphur oxide control system were developed. He explained the problem:

> "Well, here we have a timing problem because you have to start designing boilers well in advance of the unit. For a 1976 unit, we will have to start next year in making some final design decisions, and so we will not have the time to wait until we are assured that an So_2 [sulphur dioxide] removal system would be available." Wood Tr. p. 622.

Adding to the competition problems faced by coal because of growing air pollution concern and regulation, is the fact that the control of particulate pollution and sulphur oxide pollution are negatively interrelated. In present particulate control technology, sulphur oxides are needed for ionization of the flue

gases, so that equipment which reduces the sulphur oxide reduces the effectiveness of the particulate control equipment. Moser Tr. p. 1530; Wood Tr. pp. 665-66; Corey Tr. p. 1686; Defendants' Exhibit 254, p. 44. In effect, as one problem is solved, another is created.

Cost projections show that sulphur oxide pollution control equipment will be quite expensive in terms both of initial capital cost and subsequent increased operating expenditures. Such devices will be far more costly than particulate control equipment. In some cases, it was shown that the projected capital cost alone for installation of a single control device will exceed the total current $15 million Federal budget for research on the control of sulphur oxides. Defendants' Exhibit 89, Table 5, p. 43; Griswold Dep. 214-16.

The Adverse Effect of Air Pollution Control Devices on Coal Consumption

The lack of commercially acceptable sulphur oxide control devices, coupled with the increasing adoption of stringent sulphur oxide air pollution restrictions, has led to a switch on the part of many fuel consumers away from coal. As Commonwealth Edison summed up the situation in its annual report: "The best way for us to reduce air pollution is to burn less coal." Defendants' Exhibit 90, centerspread. By 1973, Commonwealth Edison will be burning 50 per cent less coal in Chicago than it did in 1967, and by 1975, Edison's coal-burn will be cut in half again.

Defendants' Exhibit 98. During 1969, the gas burned in Commonwealth Edison's plants in and near Chicago replaced nearly 1,700,000 tons of coal. Currently, an additional 1,400,000 tons are being replaced by oil. Low-sulphur coal from Montana, Wyoming, and Colorado is also being tested as a possible substitute for still more of the high-sulphur coal presently consumed by Edison. Finally, Edison has made a substantial commitment to the use of nuclear energy, particularly in its future generation plans. Gorden Corey, Chairman of Commonwealth Edison's Finance Committee, emphasized at trial that "we believe this is the best way to take care of our massive electric power generation problems with a minimum of disturbance to the environment." Corey Tr. pp. 1600-01.

Like Commonwealth Edison, Northern States Power used its annual report to advise its shareholders of the steps it is taking in the face of growing air pollution concern and regulation. The report notes the conversion, for example, of some of its plants from coal burning to gas and oil fuel, and stresses the company's commitment to nuclear energy:

> "* * * By 1974, 35 per cent of the Company's total generating capability will be in nuclear units that do not produce dust or sulphur dioxide. By 1974, NSP will burn about 4 million less tons of coal annually than would have been required if coal-burning units of comparable generating capacity had been built. This is a coal and sulphur dioxide reduction of 55 per cent." Defendants' Exhibit 149, p. 18.

Other industry witnesses also noted the erosion of coal's competitive position because of the increasing concern over air pollution, and their expectation that the competition that coal faces from other fuels would increase even more in the future. As the president of one midwest utility expressed it: "We have always discussed every alternate fuel and looked at it, and we are doing so more in recent years because of air pollution." Steele Tr. p. 956. Indeed, as another utility executive testified: "Air pollution is getting to be the overriding issue." Tomey Tr. p. 397.

Coal producers also stressed the impact of air pollution regulation on coal consumption. The president of one coal company noted, for example, that immediately after the enactment of an air pollution ordinance in St. Louis, his company lost one of its major customers because the company's coal had a higher sulphur content than permitted under the ordinance. Beck Dep. 9.

The capital and operating costs involved in air pollution controls are important economic factors which utilities will consider in determining what type of fuel to burn and what type of generating stations to construct for their system. Such costs may well lead to the exclusion of coal from the competitive picture for some utilities in favor of other fuels. The impact of air pollution abatement measures on the consumption of various fuels by electric utilities was summed up by Dr. Bruce Netschert, defendants' economic and energy exepert, as follows:

"Well, as I previously indicated, I think that the impact of the sulphur aspect of air polution regulations is to place coal at a competitive disadvantage, and this stated otherwise would mean that there would be a tendency to turn to other fuels as a means of coping with such regulations—gas, oil and nuclear.

"To answer your question specifically, I would say that the net effect would be to tend toward an increase in the consumption of these other fuels at the expense of coal consumption." Netschert Dep. 69.

In light of the commercial unavailability of sulphur oxide pollution control equipment, many of the governmental restrictions adopted to date, particularly the more recent, have taken the form of a limitation on the amount of sulphur in fuel burned rather than a limitation of the amount of sulphur oxide emissions. Defendants' Exhibit 89, Table 2, p. 14; Defendants' Exhibit 89, pp. 13, 23; Griswold Dep. 147. Furthermore, because of the time, expense, and difficulties in measuring emissions, practical enforcement of even the latter standards often takes the form of restricting the sulphur content in fuels burned. Coals whose sulphur content exceeds that proscribed by ordinance or statute cannot, of course, compete for the business of consumers located within the area of regulation. *Because of its high sulphur content, none of United Electric's coal can be sold in Chicago.*

Not only does this intense level of interfuel competition explain a great deal of what has happened

in the coal industry and to its markets, but its recognition is necessary to any valid predictions concerning the coal industry's future. Because interfuel competition particularly provides utilities with a strong bargaining weapon in negotiations with coal producers, this competition exerts strong pressure on the market in which coal producers sell their form of energy. This court is of the opinion that these pressures are crucially relevant to its assessment of the competitive effect of the United Electric-Freeman combination.

IV. THE RELEVANT PRODUCT MARKET

Based upon the extensive evidence presented at trial concerning the coal industry, its consumers and its competitors, this court is of the opinion that the energy market is the appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination. Midwest coal consumers, many of whom testified at trial, were shown to be typically large utility and industrial corporations sophisticated in the energy market. Their testimony consistently demonstrated that their purchasing decisions with respect to coal were based primarily upon a comparison of competitive forms of energy. In the context of the entire record before this court, the Government's position that coal is a "sub-market" for antitrust purposes is untenable. As succinctly stated in *United States* v. *Bethlehem Steel Corp.*, 168 F.Supp. 576, 592 (S.D.N.Y. 1958):

> "* * * Any definition of a line of commerce which ignores the buyers and focuses on what the sellers do, or theoretically can do, is not meaningful."

In determining the appropriate line of commerce, the Supreme Court has directed that economic and commercial realities must be examined. *United States* v. *Continental Can Co.*, 378 U.S. 441, 449 (1964); *Brown Shoe Co., Inc.* v. *United States*, 370 U.S. 294, 336 (1962). If competition cuts across product or industry lines, the product market must be drawn broadly enough to include competition as it exists. In the *Continental Can* decision, the Supreme Court observed that:

> "It is quite true that glass and metal containers have different characteristics which may disqualify one or the other, at least in their present form, from this or that particular use; that the machinery necessary to pack in glass is different from that employed when cans are used; that a particular user of cans or glass may pack in only one or the other container and does not shift back and forth from day to day as price and other factors might make desirable; and that the competition between metal and glass containers is different from the competition between the can companies themselves or between the products of the different glass companies. These are relevant and important considerations but they are not sufficient to obscure the competitive relationships which this record so compellingly reveals." 378 U.S. at 450. (Emphasis supplied)

The competitive battle waged by various forms of energy, as documented in this litigation, is similar to the demonstrated competition between glass and metal containers in the *Continental Can* decision. Applicable here are the Supreme Court's considerations which compelled the conclusion that an inter-industry line of commerce existed:

> "* * * In our view there is and has been a rather general confrontation between metal and glass containers and competition between them for the same end uses which is insistent, continuous, effective and quantitywise very substantial. Metal has replaced glass and glass has replaced metal as the leading container for some important uses; both are used for other purposes; each is trying to expand its share of the market at the expense of the other; and each is attempting to preempt for itself every use for which its product is physically suitable, even though some such uses have traditionally been regarded as the exclusive domain of the competing industry." *Id.* at 453.

These considerations also compel this court to conclude that since coal competes with gas, oil, uranium and other forms of energy, the relevant line of commerce must encompass interfuel competition.[33]

---

[33] In United States v. Aluminum Co. of America, 377 U.S. 271 (1964), and United States v. Philadelphia National Bank, 374 U.S. 321 (1963), decisions heavily relied upon by the Government in this action, the Supreme Court found that the requisite interproduct competition was not supported by the record. Such is not the case here.

V. THE RELEVANT GEOGRAPHICAL MARKET

The defendants have presented extensive evidence showing the distributive patterns of all the coal from the United Electric mines and other mines located in the same Freight Rate Districts. A similar showing has been made with respect to Freeman's mines and the Freight Rate Districts where they are located. The sales markets thus revealed were then analyzed to determine the likely effect of the United Electric-Freeman combination upon each of them.

The Government's proposed geographic markets, Illinois and the Eastern Interior Coal Province, are based essentially on past and present production statistics and do not relate to actual coal consumption patterns. The Government failed to produce evidence to establish the existence of a market for coal within these two proffered geographic areas. The Government's own economist testified that he had "concluded that the State of Illinois was the most appropriate market" without explaining why. Folsom Tr. p. 2469. Moreover on cross examination he could name no other factor that made the political boundaries of the State of Illinois a meaningful measure of the relevant geographic market for coal. Folsom Tr. p. 2501. There is no evidence in this record that any customer of either United Electric or Freeman purchased, or that any producer sold, coal throughout either of the Government's proposed markets. In sharp contrast with the Government's approach, the defendants' proposed markets reflect distribution pat-

terns shown by the evidence as recognized by the coal industry and the Interstate Commerce Commission, as well as by the Supreme Court. Terleke Dep. Ex. 1-11; Weir Dep. Ex. 1; Nugent Dep. Ex. 38; *Ayrshire Collieries Corp.* v. *United States, supra.*

The evidence clearly indicates that transportation costs largely determine those facilities for whose business coal mines are able to compete and those mines to which coal consumers can practicably turn for supplies. As the president of one midwest coal producer testified, "coal sales follow transportation arteries and freight rates." Beck Dep. 7. It is undisputed that the cost of transporting coal may approach 30 per cent to 40 per cent of its delivered price, and is therefore a critical factor influencing the choice of suppliers by coal consumers which can effectively segregate coal producers in one area from those in another. The evidence shows that in maps and statistical compilations used by midwest coal consumers and producers, mines located in Illinois, Indiana and western Kentucky have long been commonly grouped according to the Freight Rate Districts in which they are located. Responses to the subpoena questionnaire sent to midwest coal consumers demonstrated that each Freight Rate District serves a distinct and definable area, as did the testimony of producers and consumers.

The defendants have also identified two unique coal consumers for purposes of market delineation. Commonwealth Edison annually consumes as much coal as the combined production of all the mines in both

the Fulton-Peoria and the Springfield Freight Rate Districts, the two major Freight Rate Districts closest to its generating stations. Because of its substantial coal requirements and the location of its facilities, Commonwealth Edison must purchase coal from several Freight Rate Districts in Illinois. Moreover, in order to minimize its overall transportation costs, Commonwealth Edison has a distribution pattern for the coal which it purchases that is quite distinct from that followed by other consumers. Finally, Commonwealth Edison has the most extensive commitment to the use of nuclear energy for the generation of electricity of any electric utility in the world and has also undertaken an air pollution control program which is substantially increasing its use of nuclear energy, gas and oil.

The defendants also substantiated their contention that the Metropolitan Chicago Interstate Air Quality Control Region constitutes another unique coal market. This region, designated by Congress, consists of McHenry, Kane, Lake, Cook, DuPage and Will counties in Illinois, and Lake and Porter counties in Indiana. The City of Chicago, by far the largest municipality within this region, has already enacted air pollution control regulations which prohibit the burning of fuels with a sulphur content of greater than 2.0 per cent at the present, and 1.0 per cent after August 31, 1972. Chicago Municipal Code, Chapter 17, ¶ 17-2.5(3), as amended.

The Chicago area, because it is a major transportation hub with direct railroad or water arteries to

most of the Freight Rate Districts in the midwest, has been served in the past by producers in most midwest Freight Rate Districts. In no other significant industrial and population center in the midwest does this confluence of coal shipments from multiple Freight Rate Districts occur. Because of existing and anticipated air pollution regulations, however, the evidence discloses that future competition will be limited to those producers of low sulphur coal in the Southern Illinois Freight Rate District and in the Murdock Freight Rate District.

Just as the relevant product market must reflect commercial realities, so also must the geographic market selected for testing the competitive effects of an acquisition or merger " 'correspond to the commercial realities' of the industry" under scrutiny. *Brown Shoe Co.* v. *United States, supra,* at 336. See also *Case-Swayne Co.* v. *Sunkist Growers, Inc.,* 369 F.2d 449, 456 (9th Cir. 1966), *rev'd* on other grounds, 389 U.S. 384 (1967); *United States* v. *Northwest Industries, Inc.,* 301 F.Supp. 1066, 1083-84 (N.D. Ill. 1969); *United States* v. *Tidewater Marine Service, Inc.,* 284 F.Supp. 324, 332 (E.D. La. 1968); *United States* v. *Crocker-Anglo National Bank,* 277 F.Supp. 133, 173 (N.D. Cal. 1967); *United States* v. *Kimberly-Clark Corp.,* 264 F.Supp. 439, 457 (N.D. Cal. 1967). The Government's purely statistical approach to geographic market definition fails to measure market strength or competition as it exists. However, even were this court to accept the Government's commercially unrealistic definition of the rele-

vant geographic market, the Government's failure to show that a substantial lessening of competition resulted from the United Electric-Freeman combination is fatal to this divestiture action. *Cf.*, *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, 549-50 (1966).

VI. THE COMPETITIVE EFFECT OF THE UNITED ELECTRIC-FREEMAN COMBINATION

The record indicates an absolute decline in the number of coal producers in Illinois since 1959, as well as in the three-state area proposed by the Government as the relevant geographic market. However, the evidence clearly discloses that reduction in the number of coal producers has occurred not because small producers have been acquired by others, but as the inevitable result of the change in the nature of demand for coal. *Significantly, the United Electric-Freeman combination accounted for less of the coal produced in Illinois and the three-state area in 1967 than it did in 1959.* Accordingly, this litigation presents a very different situation from that in such cases as *United States* v. *Philadelphia National Bank*, 374 U.S. 321 (1963), and *United States* v. *Von's Grocery Co.*, 384 U.S. 270 (1966), where the Supreme Court was concerned with "preventing even slight increases in concentration." 374 U.S. at 365, n.2. Here, there is no element of "prevention," since the combination is in its second decade without demonstrating any of the indicia of concentration.

Crucial to the Government's case is proof that United Electric and Freeman are actual or potential competitors. By the use of charts, the Government points to certain common customers of United Electric and Freeman to demonstrate the requisite anticompetitive effect of the combination of these two coal producers. However, viewed in the context of all the evidence in this case, this court is of the opinion that an independent United Electric would not and could not compete with Freeman to any substantial degree.

These companies have been and are now predominantly complementary in nature. United Electric is a strip mining company with no experience in deep mining nor likelihood of acquiring it. Freeman is a deep mining company with no experience or expertise in strip mining. According to the undisputed evidence, United Electric and Freeman have made a joint proposal to a group of public utilities for development of coal lands in southern Utah. If accepted, United Electric would mine the strip coal and Freeman the deep coal. As Thomas J. Tarzy, United Electric's Vice President of Western Operations testified:

> "It is logical, and I think it made a good proposal, and I think it was well received that here were two companies, one who had expertise in strip mining and the other who had expertise in deep mining, to go in there and make a proposal to develop this property. I think it had a very beneficial effect, and without something like that,

I don't think we would have gotten much consideration." Tarzy Dep. 425.

Freeman sells metallurgical coal. United Electric does not and cannot. The Government concedes that United Electric could not compete with Freeman's sales of metallurgical coal. Freeman sells a by-product known as dust. United Electric does not and cannot.

Excluding Commonwealth Edison, none of the sales by United Electric in the period 1965 to 1967, the years chosen by the Government for analysis, would have or could have been competitive with Freeman, had the two companies been independent. The mines and coal reserves of United Electric are, and have been since prior to 1959, located in different Freight Rate Districts than the mines and coal reserves of Freeman. The Freight Rate Districts in which the mines and reserves of United Electric are located serve separate and distinct markets from those in which the mines of Freeman are located.

Freeman produces coal with a sulphur content within the low limits permitted under local and federal air pollution regulations applicable to the Chicago area, and will likely be able to continue to serve that market. United Electric does not and cannot produce such coal, and thus will not be able to serve that market.

United Electric's contract with Commonwealth Edison, both its and Freeman's largest customer, expired in 1970 and was not renewed. United Electric's sales to Wisconsin Public Service and TVA were shown

to be complementary to those of Freeman and could not have been competitive, even if the companies had been independent.

In 1965, the reserves at the Mary Moore mine of United Electric played out earlier than anticipated, before United Electric's long-term contract with Illinois Power Company for coal from that mine had expired. Freeman stepped in and supplied coal from its Orient mines for the balance of the contract. *United Electric's existing contracts with Central Illinois Light Company, Northern States Power, and Union Electric are backed up by the reserves of Freeman and could not have been obtained without that guarantee.*

Moreover, United Electric's coal reserve prospects for the future are singularly unpromising. Evidence was presented at trial by experts, by state officials, by industry witnesses and by the Government itself indicating that economically mineable strip reserves that would permit United Electric to continue operations beyond the life of its present mines are not available. The Government failed to come forward with any evidence that such reserves are *presently* available. The evidence conclusively shows the critical importance of coal reserves to the successful negotiation of long term contracts with utilities. United Electric can hardly be considered a competitive force in the utilities market without sufficient reserves.

The adequacy of crucial resources is one of the factors which should be considered in assessing the likely competitive effect of a merger. *Brown Shoe*

Co. v. *United States*, 370 U.S. 294, 346 (1962). See also *United States* v. *Pennzoil Co.*, 252 F.Supp. 962, 979 (W.D. Pa. 1965); *United States* v. *Atlantic Richfield Co.*, 297 F.Supp. 1060 (S.D.N.Y. 1969). In view of the evidence presented on this issue, this court is of the opinion that United Electric, standing alone, cannot contribute meaningfully to competition. This factor persuasively confirms the cumulative testimony of consumers and competing producers that the United Electric-Freeman combination does not adversely affect competition.

SUMMARY AND ORDERS

The evidence presented by both parties in this divestiture action fails to support the Government's contention that the effect of the United Electric-Freeman combination has been or will likely cause a substantial lessening of competition. The challenged combination has been in effect since 1959, and yet no adverse consequences with respect to competition were shown either to have occurred or likely to occur. Particularly significant is the fact that for coal producers such as United Electric and Freeman, the utility market has become, and will undoubtedly remain, the only substantial outlet for coal production. Moreover, in the utility market, producers such as United Electric and Freeman face sophisticated, knowledgeable purchasers wielding great economic power and having formidable bargaining strength. Intense interfuel competition gives utilities and other

coal purchasers additional bargaining strength and places great pressure upon coal producers to remain competitive.

The increasing concern with air pollution problems will adversely affect coal producers, particularly high-sulphur coal producers such as United Electric, thereby imposing upon them a serious competitive disadvantage in their rivalry with other fuels.

The evidence supports the defendants' contention that United Electric and Freeman are predominantly complementary rather than competitive producers. The only evidence produced by the Government to support their claim of a substantial lessening of competition was statistics which fail to reflect the very real competition coal faces from other forms of energy, and which groups together coal producers into economically unrealistic markets while ignoring the key factor in a coal producer's market strength—coal reserves. Furthermore, evidence from numerous knowledgeable industry representatives, including competitors and customers of United Electric and Freeman, confirms the defendants' contention that the challenged combination has not led, and is not likely to lead to a substantial lessening of competition.

Finally, virtually all of the economically mineable strip reserves of United Electric have been sold under long-term contracts, and United Electric has neither the possibility of acquiring more nor the ability to develop deep coal reserves. Under these circumstances, continuation of the affiliation between United

Electric and Freeman is not adverse to competition, nor would divestiture benefit competition even were this court to accept the Government's unrealistic product and geographic market definitions. This court concludes that, upon the basis of reliable, probative and substantial evidence contained in the record, the challenged acquisition does not violate Section 7 of the Clatyon Act.

IT IS THEREFORE ORDERED that judgment be, and it is hereby rendered for the defendants.

IT IS FURTHER ORDERED that the complaint be, and it is hereby dismissed.

IT IS FURTHER ORDERED that costs be assessed against the plaintiff.

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, and FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

F.I.d 10/10/72

MOTION TO AFFIRM

General Dynamics Corporation, The United Electric Coal Companies, and Freeman Coal Mining Corporation move pursuant to Rule 16 of this Court that the judgment of the District Court be affirmed. It is manifest that the decision below is correct and the questions of which review is sought are unsubstantial.

ARGUMENT

The District Court held that, "upon the basis of reliable, probative and substantial evidence contained in the record," the longstanding affiliation of The United Electric Coal Companies and Freeman Coal Mining Corporation does not violate Section 7 of the Clayton Act. (App. 66a.)[1] Chief Judge Robson concluded that "[t]he challenged combination has been in effect since 1959, and yet no adverse consequences with respect to competition were shown either to have occurred or likely to occur." (App. 2a, 64a.)

The decision below is singularly appropriate for summary affirmance.

First, the determination that the challenged combination does not violate Section 7 turned on a host of disputed and complex factual issues, each of which was resolved squarely against the government on the basis of abundant evidence. Second, resolution of the subsidiary questions of market definition was not critical to the decision, the Court stressing that no violation of Section 7 would be found "even were this court to accept the Government's unrealistic product and geographic market definitions." (App. 66a.) Third, the opinion involves no novel questions of law nor departure from precedent, nor does it raise substantial questions concerning proper criteria for assessing anticompetitive effects in Section 7 cases. Finally, there is no escaping the overwhelming record evidence that virtually all of the economically mineable strip reserves of United Elec-

[1] "J.S." references are to the Jurisdictional Statement, and "App." references are to the opinion of the District Court as set forth in Appendix A thereto. tric have been sold under long-term contracts, that United Electric has neither the possibility of acquiring more nor the ability to develop deep coal reserves, and, therefore, an independent United Electric cannot contribute meaningfully to competition. The government's contrived argument that the District Court measured United Electric's competitive potential at the wrong time misreads the opinion and ignores the record.

The record demonstrates that the outcome of this litigation is totally without competitive significance. In 1960, when the Antitrust Division, learning of the combination, took no action, the United Electric-Freeman affiliation was already six years old and had been publicly disclosed since its inception. A dozen more years have now passed. In the interim, the utility industry—sophisticated, knowledgeable purchasers wielding great economic power and having formidable bargaining strength—has emerged as the only substantial market for coal production. The intervening years have also seen interfuel competition, stringent air pollution controls and anti-strip mining legislation add a new dimension to the already intense competitive struggle to serve this market. And while United Electric operated six mines when its affiliation with Freeman began, today it operates but three; these have short remaining lives and their coal has all been sold. Far from threatening "to ripen into a prohibited effect,"[2] this longstanding affiliation never has, does not now, and never can threaten competition. The government, despite a diligent search, was unable to find a single competitor or customer who thought otherwise. Under these circumstances, and particularly in view of the fact that United Electric's terminal condition is as irreversible as it was inevitable, this case poses no issues of concern

[2] *United States* v. *E.I. duPont deNemours*, 353 U.S. 586, 597 (1957).

to anyone, save the defendants. Accordingly, the Court should not be compelled to assume the burden entailed in a plenary review, and the decision below should be summarily affirmed.

I.

THE DECISION BELOW IS CLEARLY CORRECT

On the basis of two and a half years of pretrial discovery, a month-long trial, and the submission by both sides of extensive proposed findings, briefs and replies, the District Court reached the conclusion "that the challenged combination has not led, and is not likely to lead to a substantial lessening of competition." (App. 65a.) It did so only after determining a wide range of *factual* issues concerning the economic and commercial realities which provide the setting for such a competitive assessment: the history, mines, production, reserves and capabilities of the companies whose affiliation was challenged; the history, structure, nature and dynamics of the coal industry, its products and its markets; the distribution patterns for coal; the competition which a coal producer faces from other coal producers and from suppliers of alternative fuels; the nature of coal consumers, their buying practices and bargaining strength; the characteristics, location and availability of coal reserves; and a host of other details bearing on the past and likely future effect on competition of the United Electric-Freeman combination.

The "massive quantity of evidence" (App. 2a) supporting these factual determinations included more than 10,000 pages of exhibits and more than 7,500 pages of testimony by consumers[3] and competitors, by government officials, defend-

[3] As was stated in the Government's Response to Defendant's Proposed Findings (at page 225): "The Government admits that there is testimony in the record concerning the competitive implications of this acquisition from large, medium size and small public utilities, a rural electric cooperative, federal electric authority, a retail coal dealer and several industrial concerns."

ants, experts, trade association executives, and by others. In addition, a wealth of stipulated statistical evidence was introduced into the record, including the results of a court-ordered subpoena questionnaire issued to coal producers and consumers throughout the midwest. The results of this survey constituted a census with respect to such matters as coal characteristics, coal distribution patterns, coal reserves, interfuel competition and the characteristics and capabilities of virtually every strip and deep mine in the midwest.

What emerged from this expansive record is an articulate and reasoned opinion. The numerous factual predicates for the court's conclusion that the merger had no past or prospective anticompetitive effect are clearly spelled out in detail in the District Court's opinion and are summarized below.

1. As the government recognizes (J.S. 4), the utility market has become the only substantial outlet for coal production for coal producers such as United Electric and Freeman. In that market, these companies face sophisticated, knowledgeable purchasers wielding great economic power and having formidable bargaining strength. So indisputable is this fact that the government conceded that utilities have *at least* "equal bargaining power" with coal producers in the midwest. (App. 27a.)[4] This presented, of course, a radically different consumer situation from that involved in such cases as *United States* v. *Von's Grocery Co.*, 384 U.S. 270 (1966) and *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 (1966).

2. Moreover, intense interfuel competition gives utilities and other coal purchasers additional leverage and places

[4] See Government's Proposed Findings, § VI, C(9) at p. 25.

great pressure upon coal producers to remain competitive. (App. 26a-27a, 64a-65a.) This competitive pressure will further intensify as technological progress continues and as environmental concern imposes serious disadvantages on coal in its rivalry with other fuels. (App. 14a, 33a-34a, 37a-40a, 42a-43a, 52a, 65a.) Indeed, so serious has this latter concern become that none of United Electric's coal can be sold in Chicago. (App. 52a, 62a.)

3. It was also found with respect to the coal industry that there had been intense competition among coal producers in the past which was likely to increase in the future. (App. 18a.) See *United States* v. *First Nat'l Bank of Md.*, 310 F.Supp. 157, 175 (D.Md. 1970); *United States* v. *Tidewater Marine Service, Inc.*, 284 F.Supp. 324, 339 (E.D.La. 1968); *United States* v. *Nat'l Steel Corp.*, 1965 Trade Cas. 80,604, 80,610 (S.D. Tex. 1965); *United States* v. *Ling-Temco Electronics, Inc.*, 1961 Trade Cas. 78,621, 78,639 (N.D. Tex. 1961); *United States* v. *Columbia Pictures Corp.*, 189 F.Supp. 153, 196, 202 (S.D. N.Y. 1960).

4. The increase in the size of coal mining companies, the increase in the size of mines and the reduction in the number of coal producers were found to have occurred, not because small producers had been acquired by others but as the inevitable result of the change in the nature of demand for coal. This took place as the railroad, space heating and retail markets were lost to other fuels and as utilities shifted to long-term, large-scale contracts. (App. 18a, 24a, 60a.) Significantly, the government's economist at trial agreed. (Folsom Tr. 2581.) As the testimony of a number of witnesses demonstrated, small coal producers were, for all practical purposes, in a "different business." (App. 17a.) Again, this markedly distinguished the coal industry from the business of the defendants in *Von's*, *Pabst* and *United States* v. *Philadelphia Nat'l Bank*, 374 U.S. 321 (1963).

5. The government's theory of the case was that the United Electric-Freeman combination was "an ordinary horizontal acquisition." (J.S. 9.) Accordingly, and as the court below found, crucial to the government's case was proof that United Electric and Freeman were actual or potential competitors. The evidence was, however, that an independent United Electric would not and could not compete with Freeman to any substantial degree. (App. 61a.) On the basis of testimony before the Court, it was found that none of the actual sales by United Electric in the period 1965 to 1967, the years chosen *by the government* for analysis, could have been competitive, excluding Commonwealth Edison. On the basis of stipulated data[5] and corroborative testimony, the court concluded that the Freight Rate Districts in which the mines and reserves of United Electric had been located since prior to 1959 served separate and distinct markets from those in which the mines and reserves of Freeman had been located. This lack of competitive overlap was confirmed by officials of the Tennessee Valley Authority, Union Electric Company, Dairyland Power Company, Central Illinois Light Company, Illinois Power Company, Wisconsin Public Service, Wisconsin Electric Power, Northern States Power, Electric Energy and Interstate Power Company, all major customers of United Electric or Freeman, as well as by the testimony of government officials, defendants and other coal producers and consumers.[6]

6. As confirmed by the testimony of one of its principal officers,[7] Commonwealth Edison — United Electric's and Freeman's largest customer and Illinois' largest coal con-

[5] DPF 316-320, 323-327, 330-334, 337-342, which set forth this data, were admitted by the government.

[6] See DPF 288-296, 315, 322, 329, 336, 344, 348-356.

[7] Gordon Corey, Finance Committee Chairman, had ultimate authority for Edison's coal purchases. (Corey Tr. 1580-81.)

sumer—was shown to be unaffected by the merger. (Corey Tr. 1611-13.) The evidence was that it must purchase coal from several Freight Rate Districts because of its substantial coal requirements and location of facilities. It was found to have the most extensive commitment to the use of nuclear energy for the generation of electricity of any electric utility in the world and was substantially increasing its use of gas and oil. (App. 62a, 33a, 58a.)[8] In any event, United Electric's contract with Edison expired in 1970 and was not renewed because of United's lack of reserves and Edison's low sulphur coal program. (App. 62a; see also Corey Tr. 1658-59.)

7. The "knowledgeable" record testimony of every other utility and coal consumer supported the defendants' contention that the merger had not led and was not likely to lead to a substantial lessening of competition. (App. 64a-65a). This testimony, subjected to Government cross-examination, was supplied in part by representatives of utilities accounting for the purchase of *more than 60 percent of the coal produced in the midwest for the generation of electricity*. Such testimony has significant probative value when it is reasoned and based on facts, and when it is given by knowledgeable witnesses who spell out the concrete reasons for their conclusions.[9] *United States* v. *Philadelphia Nat'l Bank*, 374 U.S. 321, 367 (1963); *International Shoe Co.* v.

[8] Recognizing the force of these facts, the government hastened to assure the court that Commonwealth Edison does not possess an "unfair advantage" over midwestern coal producers. (See Government's Proposed Findings, § VI, ¶ C(9) at p. 25.)

[9] The government's lone effort to establish that such witnesses were indifferent to, and unsophisticated concerning, the competitive implications of mergers among coal producers was made during the cross-examination of A. H. Davis, the president of Central Illinois Light Company. This elicited the fact that Mr. Davis had, in the past, taken the initiative in complaining to the Department of Justice when his evaluation led him to conclude that another merger between two coal producers *did* pose a threat to competition. (Davis Tr. 753-54.)

Federal Trade Commission, 280 U.S. 291, 299 (1930); *United States* v. *United States Steel Corp.*, 251 U.S. 417, 451 (1920). As the government has observed in other cases, such testimony "is an invaluable and time honored mode of evidence in antitrust cases where the effect on competition is in issue." See *United States* v. *Pabst Brewing Co.*, 233 F.Supp. 475, 478-79 (E.D. Wisc. 1964), *rev'd* 384 U.S. 546 (1966).

8. Finally, the evidence showed that an independent United Electric could not contribute meaningfully to competition. (App. 64a.) It was proven at trial, and is not now disputed by the government, that control of sufficient coal reserves is of critical importance to the successful negotiation of long-term contracts with utilities. (App. 63a.) However, virtually all of the economically mineable strip reserves of United Electric were shown to have been sold under long-term contracts, and the evidence was that United Electric had neither the possibility of acquiring more nor the ability to develop deep coal reserves. (App. 65a.) On the basis of reports and testimony adduced by defendants from geologists, coal consumers and producers, government officials and the government's own rebuttal witnesses (see DPF 386-430), Chief Judge Robson decided these purely fact questions solidly in defendants' favor. In view of the extensive and reliable supporting evidence in this record, it is inconceivable that a plenary review would reveal these findings clearly erroneous.

The government's trial economist on three occasions during his testimony ventured his opinion that, given these facts, continuation of the United Electric-Freeman combination would not be adverse to competition and United Electric, if divested, would not be a viable competitive force. (Folsom Tr. 2584, 2599, 2621.) The court below was compelled to agree.

In sum, the case was tried and decided on the basis of particular facts found, in weighing all of the evidence, against the government. Neither novel theory nor break with precedent was required to reach the obvious conclusion that the merger did not violate Section 7. Since it is so clearly correct, that determination should be summarily affirmed.

II.

THE MARKET DEFINITIONS ADOPTED RAISE NO SUBSTANTIAL QUESTIONS.

A. The Decision Below Did Not Turn On The Subsidiary Questions of Market Definition.

As is clear from its opinion, the District Court's resolution of the subsidiary questions of market definition were not determinative of the ultimate issues in this case. Therefore, the questions raised by the government concerning the court's choice of product and geographic market are not material.

This Court has made it clear that in an action under Section 7 an "examination of the particular market—its structure, history and probable future" is necessary to "provide the appropriate setting for judging the probable anticompetitive effect of the merger." *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 322 n. 38 (1962). It was on the basis of precisely such an examination, involving a careful assessment of "*all* of the evidence" (App. 2a, 18a, 53a, 64a, 66a), that the District Court concluded that the challenged combination did not offend Section 7.

Significantly, not one of the many factors considered by the court in reaching its decision, as we have discussed above, hinged upon resolution of the questions of market definition. These questions were thus in no sense critical to the outcome, and the court specifically held that the United

Electric-Freeman affiliation would not violate Section 7 "even were this court to accept the Government's unrealistic product and geographic market definitions." (App. 66a; see also App. 59a-60a.) The court stated (App. 60a) that in so holding it was mindful of this Court's teaching in *Pabst* that questions of market definition are "entirely subsidiary to the crucial question in this and every § 7 case which is whether a merger may substantially lessen competition." *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, 549-50 (1966).

Thus, the District Court did not use the relevant product and geographic markets which it adopted as the key to the denominator for a simplistic mathematical test. To the contrary, it rejected any such mechanistic approach and focused instead on the "crucial question" of the combination's competitive effects.

Accordingly, the trial court's choice of energy rather than coal as the appropriate *product* market *was not* the predicate for a finding that the challenged combination supplied an insubstantial share of energy resources consumed in the midwest. It was designed instead to make it clear that the court had given full recognition to the intense competitive pressures from alternative fuels which, the court concluded on the basis of substantial evidence (see App. 27a-53a), were "crucially relevant to its assessment of the competitive effect of the United Electric-Freeman combination." (App. 53a)[10]

[10] There is, of course, no real distinction between this approach and that of the 10th Circuit in the recently decided *Kennecott* case. Thus, while the court there found *coal* to be the appropriate line of commerce, it nonetheless recognized the importance of considering interfuel competition: "The examiner's determination that nuclear energy and natural gas competition should be considered was largely based on the competition which is shown to exist in the generation of electrical energy by utility companies, and unquestionably in this area of economic activity coal is in direct competi-

Neither was the District Court's *geographic* market definition a prelude to an exculpating finding of permissible market share. Rather, it was intended to facilitate an appreciation of the fact that the only coal markets which had or could be served by Freeman and United Electric were the respective sales areas of the ICC-designated Freight Rate Districts wherein their mines were located, the facilities of Commonwealth Edison and facilities located in the Chicago area. If the combination had had or might have an anti-competitive effect, it would be in those areas. (App. 57a-59a, 62a.)

In the end then, the court's product and geographic markets were chosen not to foreclose examination of the *coal* industry in the *midwest*, but rather because they helped to "explain a great deal of what has happened in the *coal* industry and to *its markets*." (App. 52a-53a; see also App. 57a-59a.) The District Court gave careful consideration, for example, to the decline in number of midwest coal producers. As has been discussed above (*supra*, p. 6), it found that these small producers had not been acquired by others but had disappeared *as the direct result of inter-fuel competition*. (App. 18a, 60a.)[11]

---

tion with other fuels, and so it seems reasonable to consider as did the examiner the competition that exists between coal and other fuels, at least in the mentioned context." *Kennecott Copper Corp.* v. *Federal Trade Commission*, 5 Trade Reg. Rep. (1972 Trade Cas.) ¶ 74,157 at 92,834 (10th Cir.). See also *United States* v. *First Nat'l Bank of Md.*, 310 F.Supp. 157, 168 (D.Md. 1970).

[11] Similarly, the government's protestations about a "pronounced trend toward concentration" (J.S. 20) simply will not square with the trial record. The evidence was that, apart from Peabody Coal Company, the share of production accounted for by the two, four and ten largest producers had since 1959 either remained stable or, in some cases, declined. Presumably, the competitive implications of the growth in the share of midwest coal production accounted for by Peabody have been rectified to the satisfaction of the government by the consent decree in *United States* v. *Peabody Coal Co.*, 1967 Trade Cas. 84,376 (N.D. Ill.). See also GX 64, 72, 77,

In contrast to the "pragmatic, factual approach"[12] of the District Court, the government's "purely statistical approach" failed "to measure market strength or competition as it exists." (App. 59a.) Not only did the government's statistics "fail to reflect the very real competition coal faces from other forms of energy" and group "together coal producers into economically unrealistic markets," but they also ignored completely "the key factor in a coal producer's market strength—coal reserves." (App. 65a.)[13] Just how deficient the government's statistics were in light of the latter infirmity may be seen from the fact that although Humble Oil is estimated to control three and one quarter billion tons of deep coal reserves in the midwest (DX 61), it was not even listed as a competitor by the government because its initial mine had not yet come on stream and it thus had not yet started reporting production data.

The inadequacy of the government's approach to the case at bar was further demonstrated by the government's actions during the effecting of the consent decree in the *Peabody* case (*supra*, note 11). The Antitrust Division went on record there (DX 37) that it would approve "without reservation" a merger of the Midland operation (which Peabody had consented to sell) and Zeigler Coal and Coke

---

85; DX 84, 237; Steiner Tr. 2230-43. As for the combined United Electric-Freeman, the record shows, and the trial court found, that it *"accounted for less of the coal produced . . . in 1967 than it did in 1959."* (App. 60a, emphasis in original; see also App. 10a.) Significantly, the trial record also showed that the *deconcentration* trend in the midwest would accelerate as Humble Oil brought its three million-ton mine on stream (App. 41a), as Peabody divested itself of a six million ton per year operation (DX 84), and as additional United Electric mines closed as their reserves played out. (App. 7a.)

[12] *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 336 (1962).

[13] For a detailed discussion of the crucial role which reserves play in a coal producer's competitive efforts, see the trial court's opinion at App. 16a-24a.

Company. This combination would have been structurally indistinguishable from United Electric-Freeman, with the resulting combination in either situation constituting the second largest coal producer in Illinois and the midwest. The government's willingness to approve a Zeigler-Midland merger "without reservation" casts doubt on both the seriousness and the substance of its contention that anti-competitive effects will follow from a continuation of the United Electric-Freeman affiliation and would seem dispositive of the issue.[14] Significantly, when he was asked to make a competitive assessment of Zeigler-Midland following a simplistic statistical approach, the government's economist at trial balked, stating, "I would still want more information. I would still want to look further." (Folsom Tr. 2591).

That the District Court's focus on the "crucial question" of the combination's likely competitive effects was sound both in fact and in law is, defendants submit, beyond question. Whether it is technically correct to designate the relevant product market energy or coal, there can be no escaping the hard facts of record with respect to the "crucially relevant" pressures on coal producers such as United Electric-Freeman arising from the vigorous interfuel competition existing in the market place. The same is true of the relevant

---

[14]The government's inconsistent and irreconcilable actions also raise basic questions of fundamental fairness in the enforcement of the antitrust laws. We have here not a case where the government has merely taken no action on the one hand, while bringing suit on the other. Rather, it is a unique situation where the Antitrust Division has taken *affirmative* and contradictory action with respect to structurally identical mergers, approving one "without reservation" while simultaneously seeking to dissolve the other. Recognizing the questionable nature of such action, the Chief of the Antitrust Division's Chicago office has stated on the record that he has "some sympathy with the defendants [United Electric-Freeman] in the Zeigler matter." (Transcript of Pre-trial Conference of October 3, 1969, p. 10.) The Zeigler-Midland affair is discussed in detail in Defendant's Proposed Findings 449-456.

geographic markets: whether United Electric and Freeman are said to serve different areas within a market or different markets, "viewed in the context of all the evidence in this case . . . an independent United Electric would not and could not compete with Freeman to any substantial degree." (App. 61a.)

In light of such economic and commercial realities found to exist by the trial court on the basis of substantial evidence, it is clear that subsidiary technicalities of market definition were not determinative of the decision below. A remand of this case with directions to the court to adopt the market definitions urged by the government would thus occasion no change in the outcome of this litigation.[15]

B. The Market Definitions Adopted Do Not Require Review By This Court.

The Product Market

There was nothing either factually or legally novel in the District Court's examination of the likely competitive effects of the United Electric-Freeman merger within the framework of an energy market. Indeed, the Federal Trade Commission recently sent to Congress a report by its Bureau of Economics on interfuel substitutability (focusing largely on utility consumers) which finds that the results of its study support the conclusion that "an energy market exists." FEDERAL TRADE COMMISSION STAFF REPORT, INTERFUEL SUBSTITUTABILITY IN THE ELECTRIC UTILITY SECTOR OF THE U.S. ECONOMY 115 (1972). The purpose of the report was to analyze the extent of interfuel

[15] In *Brown Shoe*, this Court declined to consider whether the district court had been correct in rejecting certain proposed market definitions where such markets, even if proper, would not "aid us in analyzing the effects of this merger" and where the appellant could "point to no advantage it would enjoy" even if the markets in question were used in lieu of those employed by the district court. 370 U.S. at 327.

substitution "in order to establish the product boundaries between the various energy sources." *Id.* at 2. In doing so, it confirmed that coal, gas and nuclear energy trade in a "single market," and that "the primary fuels are generally good substitutes for one another." *Id.* at 115-16.

In his dissenting opinion in the Court of Appeals stage in the *Tampa Electric* litigation, Judge Weick was similarly persuaded that

> "there exists such a degree of cross-elasticity between coal and other boiler fuels as to constitute boiler fuels the relevant line of commerce in this case. Each of the boiler fuels—coal, oil, gas and atomic energy—is utilized in the same manner to produce the same result. As each is consumed power is produced to drive the generators which in turn produce electric energy."[16]

Numerous other cases have recognized the existence of interfuel competition as well. *See, e.g., Federal Power Commission* v. *Hope Natural Gas Co.*, 320 U.S. 591, 609 (1944); *Fuels Research Council, Inc.* v. *Federal Power Commission*, 374 F.2d 842, 845, 850, 852-54 (7th Cir. 1967); *National Coal Association* v. *Federal Power Commission*, 247 F.2d 86 (D.C. Cir. 1957); *Mississippi River Transmission Corp. and United Gas Pipe Line Co.*, 41 FPC 555 (1969); *Natural Gas Pipeline Co. of America* v. *New York Central RR. Co.*, 323 ICC 75 (1964); and *Natural Gas Pipeline Co. of America*, 28 FPC 731 (1962).

In its papers to this Court, the government all but concedes that the District Court was correct in finding energy to be *an* appropriate line of commerce within which to ex-

[16] *Tampa Electric Co.* v. *Nashville Coal Co.*, 276 F.2d 766, 780 (6th Cir. 1960), *rev'd*, 365 U.S. 320 (1961). In its reversal of the majority opinion, this Court found it unnecessary to decide whether boiler fuels, rather than coal alone, was the appropriate line of commerce. 365 U.S. at 328-30.

amine the competitive effects of the challenged combination. (J.S. 12.) It would fault the District Court, however, for its supposed "failure to recognize" that coal is an *additional* line of commerce for testing the combination's competitive effects. (J.S. 14.) But as we have noted, the District Court did not choose energy as the framework for its analysis in order to ignore the merger's competitive implications within the coal industry. Rather, such choice was made because it assisted in explaining "what has happened in the *coal* industry and to *its* markets." (App. 52a-53a.)

The claim that the District Court overlooked this Court's teachings in *Brown Shoe* is without substance. *Brown Shoe* teaches that submarkets *may* exist not that they *must* exist. Indeed, this Court rejected several of the submarkets urged in *Brown Shoe* itself, stressing that "the boundaries of the relevant market must be drawn with sufficient breadth . . . to recognize competition where, in fact, competition exists." 370 U.S. at 326.[17]

In this case, what the government really despairs of is nothing more than the District Court's refusal to make its

---

[17] As to the government's claim (J.S. 13) that coal meets "all" of practical indicia of a submarket set forth in *Brown Shoe*, the record is simply to the contrary. The evidence shows, and the court found, that coal has the same "uses" as the alternative fuels with which it competes (App. 27a), that it has the same "customers" (App. 29a-40a), that coal prices have a high degree of "sensitivity to price changes" of other fuels (App. 13a, 28a-29a, 36a-39a, 43a-44a, 51a-52a) and that the "industry and public"—and, indeed, the government itself—view coal as an integral part of the energy market and not as a "separate economic entity." (App. 13a-14a, 29a, 31a-32a.) The situation in the present case thus contrasts sharply with that in *Reynolds Metals* (referred to at page 15, note 9 of the government's Jurisdictional Statement) where the court of appeals held that "florist foil may rationally be defined . . . as comprising the relevant line of commerce in terms of (1) public and industrial recognition of it as a separate economic entity, (2) its distinct customers and (3) its distinct prices." *Reynolds Metals Co.* v. *Federal Trade Commission*, 309 F.2d 223, 227 (D.C. Cir. 1962).

assessment under Section 7 *solely* on the basis of coal production statistics. As was found, however, these fail to reflect the "very real competition" coal faces from alternative fuels, they obscure actual coal marketing patterns, and they ignore reserves, "the key factor in a coal producer's market strength." (App. 65a.) This was the "coal submarket" approach urged by the government below and found by the District Court "in the context of the entire record" to be "untenable." (App. 53a.)

The government is clearly wrong in its belief that the Court's product market choice is a substantial question which this Court should consider through a review of the entire trial record. As has already been discussed, the District Court specifically stated that its use of energy as the appropriate product market was not crucial to its decision. (App. 66a.) Moreover, it took care to make it clear that its decision to use an energy market was made on the particular factual record before it and with respect to the particular merger before it. The rejection of coal as a submarket was only made "in the context of the entire record before this court." (App. 53a.)[18]

Finally, reversal of the decision below is not required to establish that coal may be used as a product market when the facts warrant. In an opinion issued subsequent to the

---

[18] Federal antitrust enforcement authorities are already on record as recognizing this. In discussing the decision below in its brief to the 10th Circuit in the *Kennecott* case, *supra*, note 10, the Federal Trade Commission made the following observation: "While the record in that case is not before the Court, the District Court apparently concluded on the basis of the record in that case that the various fuels used by electric utilities constitute a single product market. Here . . . the Commission concluded, on the basis of trade realities reflected in the record of *this* case (I, 327-31), that coal, '[w]hether a market or a submarket,' is a relevant product market for the purposes of *this* case." (Brief For Federal Trade Commission, pp. 33-34, n. 40; emphasis in original.)

filing of the Jurisdictional Statement by the government in the present action, the 10th Circuit held, on the basis of a *different factual record* and in a *different geographic context*, that coal was the relevant product market for assessing the likely competitive effects of the merger there under consideration. *Kennecott Copper Corp.* v. *Federal Trade Commission*, 5 Trade Reg. Rep. (1972 Trade Cas.) ¶ 74,157 at 92,834 (10th Cir.)[19]

The Geographic Markets

Defendants submit that the District Court was correct in rejecting the government's approach to coal markets in this action. The government proposed two "markets" at trial, the midwest[20] and Illinois, and introduced statistics showing that a significant percentage of the coal consumed in these geographical areas was produced within them.

But the fact that 82 percent of the coal consumed in Illinois is produced in Illinois, no more demonstrates it to be a market than the fact that 100 percent of the coal sold in the western hemisphere is produced there indicates that there is a western hemisphere coal market. While such data may indicate that the market is *no larger than* the area in question, it plainly provides no insight as to whether the area is itself a market.

Coal is, of course, a transportation intensive commodity. This Court has long been aware that "[a]difference of a few

---

[19] As has already been noted (*supra*, p. 11, n. 11), despite the difference in technical product market definitions, there was no real difference in the approach to interfuel competition taken by the 10th Circuit in *Kennecott* and by the District Court below in the present action.

[20] The government restyled the midwest as the "Eastern Interior Coal Province Sales Area." Not a single witness supported the existence of such a market, and the government's own economist admitted three times during his testimony that he had "problems" with its use. (Folsom Tr. 2469-70, 2536, 2608-09; and see DPF 368-73).

cents per ton in the transportation charge is normally sufficient to divert a coal contract from one mine to another." *Ayrshire Collieries Corp.* v. *United States*, 335 U.S. 573, 586 (1949). It is not surprising, then, that the District Court found that the "evidence clearly indicates that transportation costs largely determine those facilities for whose business coal mines are able to compete and those mines to which coal consumers can practicably turn for supplies." (App. 57a; see also App. 19a-20a.)

As the court observed, "[r]esponses to the subpoena questionnaire [which the District Court had ordered] sent to midwest coal consumers demonstrated that each Freight Rate District serves a distinct and definable area, as did the testimony of producers and consumers." (App. 57a.) Indeed, even the Bureau of Mines economist who prepared the statistics used by the government recognized that the market areas in which coal can be sold are determined by Freight Rate Districts and not by state boundaries. He testified that his statistics did not deal with specific markets and conceded that "anyone with even a minimum amount of knowledge of the coal industry" knows that consumers in the Fulton-Peoria area, for example, cannot be sold coal from Southern Illinois on a competitive basis. (Gallagher Dep. 3, 100, 103-04; see also DPF 344, 371.)[21]

The shortcoming of the government's market delineation procedure in drafting its complaint, then, was simply that it was incomplete. Had the government carried its own

[21] In rejecting the "markets" proferred by the government, the District Court was also no doubt influenced by the testimony of the government's economist that "you have to have the testimony from the people about the fact that they buy coal from all over this area, et cetera, to justify saying this is a market." (Folsom Tr. 2608.) As the court's opinion noted, "[t]here is no evidence in this record that any customer of either United Electric or Freeman purchased, or that any producer sold, coal throughout either of the Government's proposed markets." (App. 56a.)

technique one step further, it would have found, as did the trial court, that the ICC-designated Freight Rate Districts in which the mines of United Electric and Freeman were located[22] serve the "separate and distinct" sales areas of each Freight Rate District, the facilities of Commonwealth Edison and facilities located in the metropolitan Chicago area. (App. 57a-59a, 62a.) In keeping with this Court's teaching in *Brown Shoe* that the geographic framework within which the effects of a merger are examined must " 'correspond to the commercial realties' of the industry" (370 U.S. at 336), the District Court designated these markets as the relevant geographic markets in this proceeding.[23]

The government's claim (J.S. 16) that the markets adopted below "exclude all sales to Chicago [and] all sales to Commonwealth Edison" is wrong. Far from being excluded, sales to Chicago and Edison were specifically identified and carefully considered by the trial court. (App. 57a-59a, 62a.) That the government knows full well that the geographic markets adopted by District Court are not based on "enormous exclusions" is confirmed by its own admission in advance of trial that "[i]n 1967, approximately 97 percent of the production in the Fulton-Peoria Freight Rate District, 100 percent of the production in the Springfield Freight Rate District, 98 per-

---

[22] United Electric's mines were shown to be in the Fulton-Peoria and Belleville Freight Rate Districts, while Freeman's mines were shown to be in the Springfield and Southern Illinois Freight Rate Districts. (App. 4a, 6a, 9a-10a; Weir Dept. Ex. 1; Nugent Dep. Ex. 38.)

[23] It should be noted in this regard that the distribution patterns which formed the basis for the markets adopted by the trial court were not "alleged"—as the government now styles them (J.S. 15)—but rather *stipulated* in advance of trial. (See DPF 316-20, 323-27, 330-34, 337-42.)

cent of the production in the Belleville Freight Rate District and 85 percent of the production in the Southern Illinois Freight Rate District, was shipped to one or more of [these] market areas. . . ." (DPF 342.) Where two or more separate markets have been identified, the statement that sales to one market "exclude" sales made to another market is a tautology and meaningless.[24]

There is nothing novel in the District Court's factual approach to analyzing coal marketing patterns. To the contrary, both its choice of markets and rejection of the alternatives proposed by the government involve merely a recognition of the economic realties underlying an appreciation that even the most unsophisticated laymen have had for some 400 years: you don't "carry coals to Newcastle." JAMES MELLVILLE, AUTOBIOGRAPHY 163 (1583).

In any event, the District Court's finding that the markets served by the Freight Rate Districts in which the mines of United Electric and Freeman are located provide the appropriate geographic framework for assessing the likely effects of the challenged combination is confined to the record facts of this case. It no more conflicts with *Pabst*[25] or precludes the use of a state or regional geographic framework in future proceedings than does the holding in *Kennecott* (stipulated to by the government) that a *na-*

---

[24] That omitting dust is proper in analyzing coal distribution patterns is established by substantial evidence. The records shows that dust is a by-product of metallurgical coal and, like metallurgical coal, is a non-competing product with a market of its own. (See DPF 351-54 and record references cited therein.) As for the charts introduced by the government at trial purporting to show common customer shipments, these were thoroughly discredited at trial. (See generally App. 62a-63a; DPF 347-356; Defendant's Post-Trial Brief, pp. 72-80.)

[25] *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 (1966).

tional geographic framework provided the proper framework for assessing the competitive implications of the merger there under consideration. *Kennecott Copper Corp.* v. *Federal Trade Commission, supra,* ¶ 74,157 at 92,834.

• • •

A plenary review of the trial record in this direct-appeal case would place a "great burden" on this Court, now faced with substantial and increasing demands on its time to consider a broad spectrum of legal issues.[26] Under these circumstances, and because the "entirely subsidiary" market definition questions of which review is sought are unsubstantial and not determinative, the decision below should be summarily affirmed.[27]

---

[26] *United States* v. *Singer Manufacturing Co.*, 374 U. S. 174, 175, n. 1 (1963). See also *Brown Shoe Co.* v. *United States*, 370 U. S. 294, 355 (1962) (Clark, J. concurring opinion); *United States* v. *Borden Co.*, 370 U.S. 460, 477, n. (1962) (Harlan, J. dissenting opinion).

[27] The government's slur on the independence and integrity of the opinion below is wholly unwarranted and should be repudiated. The assertion (J.S.11, n.8) that two parts of the district court's six-part opinion were taken *verbatim* from Defendants' Proposed Findings of Fact is spurious. Of the 145 proposed findings referred to by the government, no less than 112 were omitted, revised or supplemented. Further, of the 33 proposed findings that *were* adopted *verbatim*, 22 were admitted in whole or in part by the government. There can be no doubt then that the trial court's opinion is truly its own. Chief Judge Robson, who heard all of the evidence and spent nearly two years fashioning his decision, was the coordinating judge in the civil electrical antitrust cases, an original member and the first chairman of the Judicial Coordinating Committee for Multiple Litigation and one of the principal architects of the Manual for Complex and Multidistrict Litigation.

III.

THE COURT'S CONCLUSIONS WITH RESPECT TO UNITED ELECTRIC'S LACK OF COMPETITIVE POTENTIAL WERE CORRECT AND SUPPORTED BY SUBSTANTIAL EVIDENCE

Industry Field and Round Prairie

The government's lay speculation (J.S. 22-24) that United Electric could survive as an independent coal producer on the basis of its Industry Field strip reserves and its Round Prairie deep reserves was rejected by the trial court on the basis of abundant record evidence. These fact questions were among the principle issues below and were decided on the basis of reports and expert testimony from geologists, mining engineers, industry witnesses and defendants. The District Court agreed these reserves were not mineable and could not be developed by United Electric (App. 9a-10a, 63a). Surely, resolution of these types of questions, on the basis of all the evidence, is peculiarly within the province of the trier of fact.

The government's claim that Industry and Round Prairie hold the key to a successful future for United Electric has the same hollow ring it had below following government counsel's confession that "as of today they are not commercially valuable." (Transcript of Pre-trial Conference of October 3, 1969, p. 23.)

Apart from the obvious fact that the twelve and a half million tons of coal at Industry would hardly be sufficient for the opening of a modern coal mine (see App. 16a-18a, 21a-22a), the evidence was that the field has no mining potential. The coal seam is thin, the overburden ratio high,[28] unfavorable mining conditions are present and the

[28] Overburden ratio expresses the amount of overburden (cubic yards) which must be removed to uncover a ton of coal. (App. 16a, n. 17.)

field is distant from transportation arteries. Moreover, the high sulphur content of the coal bars it from any market where air pollution controls are keyed to that factor.[29]

An evaluation of the Industry Field by the firm of Paul Weir Company—consultants for the Federal Government, coal producers, railroads, electric utilities and financial institutions, and acknowledged by one of the government's own witnesses to be one of the most widely known and highly regarded mining engineering companies in the world (Hopper Tr. 1894; see DPF 38)—confirmed the reserves had no promise. (DX 87.) During his deposition by the government, Mr. Weir testified that "I don't think these reserves will ever be mined, in any circumstances." (Weir Dep. 60.) The government's attempt to present trial testimony to the contrary failed completely. (See Hopper Tr. 1876-78, 1895-1901.)[30]

The government's Industry Field contention is further betrayed by the inference that United Electric has still *other* uncommitted but mineable strip reserves. (J.S. 23; see also J.S. 2 and 12.) These "other reserves" consist of a patch of less than 350,000 tons separated from United

[29] See DPF 391-396 and record references therein cited. Hereafter, references to defendants' proposed findings below are meant to include the record references set forth in those findings.

[30] The government completely misquotes the testimony of the former UEC president. (J.S. 23-24.) Mr. Nugent said Industry would *not* be mined, under any circumstances, until "all of the commercially mineable coal in Fulton County is exhausted" and placed that finality twenty years in the future, not ten to twelve. (Nugent Dep. 343, 346.) Not only did his deposition testimony in its entirety (*id.* at 338-47) make clear the field had no promise ("this was a most uneconomical proposition and a most unwise investment," *id.* at 342), but Mr. Nugent's trial testimony on the subject two years later was similarly pointed: "With the further development of nuclear energy, my present thinking is that the Industry Field will probably never be mined and that the company had better take its licking now and dispose of the land, at farm prices if need be." (Nugent Tr. 1946; see also Tr. 1983-85.)

Electric's Buckheart mine and unreachable, and a similarly isolated tract of 1,700,000 tons some distance from the company's Fidelity mine. In its post-trial papers, the government was candid enough to admit that "these reserves, by themselves, could not support a new mine operation." (Gov't. Resp. to DPF 397, p. 204.)

The government takes no issue with the court's finding that United Electric does not have the possibility of acquiring additional economically mineable strip reserves. (App. 65a.) It could not credibly do so, in view of the substantial evidence presented at trial "by experts, by state officials, by industry witnesses and by the Government itself indicating that economically mineable strip reserves that would permit United Electric to continue operations beyond the life of its present mines are not available." (App. 63a; see also DPF 398-411.)

Equally dispositive was the evidence with respect to the deep coal reserves at Round Prairie and United Electric's inability to mine them.

As the Court found, again in one of the major factual disputes below, "United Electric is a strip mining company with no experience in deep mining nor likelihood of acquiring it." (App. 61a.) The government admitted that until 1959, in communications with stockholders, landowners and others in the industry, United Electric held itself out as strictly a strip mining organization. (Gov't. Resp. to DPF 101, p. 18.) In its 1956 Annual Report, the company stated "[f]or thirty-eight years your Company has been engaged in a single business—mining bituminous coal by the strip or open pit method." (GX Kolbe Dep. Ex.2 p. 7.) The government's Statement of Facts misleads the Court when it says United Electric "has not operated an underground *mine* since 1954." (J.S. 8.) As the government admitted, this was

a "short lived and unsuccessful drift *operation*"[31] at one of United Electric's strip mines between 1952 and 1954. (Gov't. Resp. to DPF 103, p. 19.) There was no underground *mine* at all.

While the government would like to make something of the fact that United Electric began acquiring its Round Prairie deep reserves in 1958, "the year before Material Service assumed control of UEC" (J.S. 22), it overlooks the fact that it admitted to the District Court that the United Electric-Freeman affiliation was initiated in 1954 and that "[s]ince *at least 1958*, UEC has made it a practice to confer with Freeman regarding any deep mining possibility." (Gov't Resp. to DPF 113, 124, pp. 22-23.) The evidence demonstrated that United Electric never gave real consideration to deep coal reserves until it and Freeman's management had become closely associated. (See DPF 114.)

The government purports to rely on the testimony of Nicholas Camicia, president of *both* Freeman and United Electric in the late 1960's, in contending that all one needs is money to undertake successfully deep coal mining. (J.S. 23.) What the government omits to state is that Mr. Camicia—by the time of trial, president of the Pittston Company, one of the country's largest deep coal producers—testified that based on his professional knowledge and expertise as a deep mining engineer and executive, he did not see how United Electric could possibly make a successful grass roots entry into the deep mining of coal and "[t]hey would have made a mistake if they had tried." (Camicia Tr. 1393, 1422.)

The expert opinion in the record was that United Electric's experience as a strip miner would be of no assistance

[31] Drift mining involves merely punching into an already exposed seam of coal, usually from the pit floor. (See Camicia Tr. 1388-91.)

to it in attempting to undertake deep mining operations. (DX 87, pp. 28-30; Camicia Tr. 1392-93.) The government admitted that the extraction processes and technology are different for strip and deep coal mining, (Gov't. Resp. to DPF 415, p. 214) and that deep mining poses different engineering problems and working conditions from strip mining. (*Id.*, DPF 417, p. 215.) Further, the testimony of a number of utility consumers confirmed that because of the complexities, difficulties and risks which deep mining involves, a large buyer of coal would be reluctant to enter into a contract for deep coal with a company with no proven experience. (See DPF 419-20.) As observed by the 10th Circuit in the *Kennecott* case, the "essentials" for new entry into the coal business are "extensive reserves and ready ability to deliver," "experience, know-how and equipment." *Kennecott Copper Corp.* v. *Federal Trade Commission*, *supra*, ¶ 74,157 at p. 92,836 (10th Cir.). As for deep mining, United Electric has none of these.

Given the fact that, as the record supports, there is no reasonable probability that United Electric could successfully undertake deep mining, there is therefore no reasonable probability that it would try. Both common sense and the government's own prior observations belie the validity of any parallel (J.S. 22-23) between what Humble Oil, subsidiary of the world's largest industrial corporation, would do and could do, and what an independent United Electric might successfully undertake. The government pointed out (DX 81-83) in *United States* v. *Standard Oil Co. (New Jersey)*, 253 F.Supp. 196 (D.N.J. 1966), that there is no correlation between Standard Oil's ability to make a grass roots entry into deep mining and that of a smaller company attempting a similar venture. (*Id.* at 200, 208, 223, 227.) In any event, Humble's mine had not opened at the time of trial and as one witness put it, "the jury is still out" as to whether it will be successful. (Camicia Tr. 1424.)

The government's reference to Ayrshire Collieries (J.S. 23) is less than candid. While it is true that Ayrshire did develop a deep mine after many years of operating as a strip miner, it did not do so *until after acquiring two deep mine companies*. Even so, the mine has been a failure and Ayshire has written off five million dollars of its investment and would "absolutely not" have undertaken the venture had it known what was in store. (Hopper Tr. 1878-81).

Finally, the evidence was that United Electric's only deep coal reserve field, Round Prairie, was not mineable by *anyone* in the near future. (See DPF 428-29.) The government admitted "they may not be commercially mineable at the present time." (Gov't. Resp. to DPF 429, p. 220.)

As with all the other central questions of fact in this case, the District Court's findings with respect to United Electric's competitive potential were based on the evidence in the record. We submit that if that record is reviewed, it cannot be reasonably maintained that there is not substantial evidence to support the trial court's conclusion that "virtually all of the economically mineable strip reserves of United Electric have been sold under long-terms contracts, and United Electric has neither the possibility of acquiring more nor the ability to develop deep coal reserves." (App. 65a.)

The Argument that United Electric's Competitive Potential was "Cut Off" has no Merit

The government concedes that the District Court was correct in assessing whether the challenged acquisition may substantially lessen competition "from the vantage point of the time of suit." (J.S. 21). Neither does the government quarrel with the logic of the conclusion that if United Electric has no competitive potential, continuation of its affiliation with Freeman poses no anticompetitive threat. Even the

government's trial economist repeatedly agreed. (Folsom Tr. 2584, 2599, 2621.) The government counters, however, that the court below erred in failing to determine the "competitive potential cut off by the acquisition" in 1959. (J.S. 2, 22.) This contention is contrived and has no merit.

The government grasps for straws in citing two sentences (J.S. 21) out of the court's 73 page opinion which it contends demonstrate that the court measured United Electric's competitive potential at the wrong time. As the government knows full well, the court's observation that there was no evidence that "reserves are *presently* available," and that "United Electric *has* [not] the ability to acquire more," (App. 63a; emphasis is original) were not intended to contrast United Electric's condition and prospects at trial with those obtaining in 1959. Rather, they were responsive to the government's speculations at trial—repeated here (J.S. 23-24)—that mining conditions have changed in the past, that they may continue to change, and that "properties which UEC has investigated in the past . . . may become economically strippable in the future." (Govt. Post-Trial Brief, p. 141; see also Def. Post-Trial Brief, pp. 88-89.)

Although the government, until the filing of its Jurisdictional Statement, had never suggested—much less urged—that the court measure United Electric's competitive potential in *1959*, the trial court time-and-again specifically addressed itself to the 1959 evidence. For example, "[t]he challenged combination has been in effect *since 1959*, and yet no adverse consequences with respect to competition were shown either *to have occurred* or likely to occur," (App. 64a); "[t]he combination is *in its second decade without demonstrating* any of the indicia of concentration" (App. 60a); "[t]he mines and coal reserves of United Electric are, *and have been since prior to 1959*, lo-

cated in different Freight Rate Districts than the mines and coal reserves of Freeman" (App. 62a); and "[t]hese companies *have been* and are now predominantly complementary in nature" (App. 61a).[32]

The government's criticism (J.S. 20-21) of the court's concern with events in the period immediately preceding and surrounding the trial comes with ill grace. As the decision of the trial court points out, these were "the years chosen by the Government for analysis." (App. 62a.) Thus, the principal focus of the complaint is on 1965 to 1967 (Complaint ¶ 11-20); the government's alleged common customer charts were confined to the 1965-67 (GX 85-91); all of the government's concentration and market share charts combined United Electric and Freeman data only in 1967 and subsequent years (GX 73, 86; compare GX 71 with GX 72, and GX 84 with GX 85); and the government advised the trial court that its coal industry rebuttal witnesses would be called to testify "as to the *availability* of strip and underground coal reserves" and "future strip mining possibilities." (Government Counsel, Tr. 1377).

The government's argument (J.S. 24) that "if UEC does not now have adequate reserves, or the prospects of acquiring more, it is because of management policies imposed on it *after* the acquisition," is totally at odds with the record evidence.

---

[32] It is not surprising that the District Court found nothing in the 1959 evidence indicating a Section 7 violation. The Antitrust Division in its investigation at that time did not even view the situation as warranting the issuance of a complaint. As the District Court's opinion notes, shortly after Material Service achieved common control of UEC and Freeman, Material Service was itself acquired by General Dynamics. "An investigation by Antitrust Division of the Department of Justice ensued, during which the Government was furnished information with respect to the stock ownership of Freeman and United Electric. No further action was taken by the Government." (App. 8a)

The events which decreed that United Electric would reach the end of its competitive significance in the 1960's did not take place *after* 1959, as the government would like to have it, but in the years long prior to that date.

As has been discussed at pages 26-27 above, United Electric's failure to acquire experience in deep coal mining had been the conscious choice of United Electric management since the 1920's. That this destined United Electric to a future of exclusively strip mine operations (absent merger with a significant deep coal producer), is confirmed by the fact that, except for Humble Oil,[33] no company has even attempted to open a large-scale deep mining coal operation on a grass roots basis in recent history in the midwest. (See DPF 24.)

With respect to strip coal reserves, again it was the conscious choice of United Electric management prior to 1959 not to be aggressive in its acquisition of additional coal reserves.[34] (Kolbe Dep. 189, 300-02.) The government admitted that prior to 1955 United Electric acquired *only seven* of the more than 200 fields of coal reserves it had examined. (Gov't Resp. to DPF 84, p. 9.) As a result, and as the government also admitted, by 1960, Peabody Coal Company, Truax-Traer, Ayrshire Collieries, Southwestern and Midland Electric Coal Companies (all predominant or exclusively strip mine companies) had reserves substantially greater than United Electric. (Gov't Resp. to DPF 86-87,

[33] But see page 28, *supra*.

[34] The facts with respect to United Electric's poor pre-merger reserve acquisition policies and capabilities and the post-merger steps to improve the situation were detailed in Defendant's Proposed Findings 84-123. It was because of its debilitated condition prior to the challenged merger that United Electric, as the District Court's opinion noted, had made a number of "unsuccessful attempts to merge with, or to acquire, other Illinois coal producers." (App. 8a, n. 7.)

p. 11.) It was in the 1950's and before that the scramble for strippable coal reserves took place. United Electric, under its pre-merger management, chose not to participate in that contest. (See DPF 84-89, 91.)

So intense was this competition for reserves that, according to the opinion of one expert geologist (whose principal occupation since 1932 had been the acquisition of coal rights for sale to producers) "by 1960, there was no longer any possibility of acquiring or establishing, for transfer to coal producers, any new economically mineable strip coal acreage in the Illinois basin [Illinois, Indiana and West Kentucky] of sufficient size to justify the opening of new mines." (DX 88: Organ Dep. *passim*.) This was confirmed by the testimony from other companies that had been unsuccessful in searching for midwestern strip coal reserves at the end of the 1950's and after. (Dorrance Dep. 11; stipulated testimony of George Shipley (Humble).)

The evidence showed that once control of United Electric was gained in 1959 by Material Service-Freeman, vigorous efforts were commenced to acquire additional reserves. (See DPF 92-97.) United Electric was even then having trouble with its utility customers because of its reserve position. (See DPF 89.) Accordingly, and as the government admitted, United Electric investigated many potential strip coal areas throughout Illinois, Indiana and Kentucky, but these efforts were unsuccessful. None of the fields examined were found to contain economically mineable coal. (Gov't. Resp. to DPF 95-96, p. 16.)

In the face of the concession in its Response to Defendants' Proposed Findings that, "the Government admits that after 1959, UEC's management sought to acquire economically recoverable reserves, i.e., reserves which were merchantable and capable of making a profit," (*id.* at p. 15) it ill becomes the government now to contend that United

Electric's management policies after 1959 are to blame for the company's lack of adequate reserves.

The government's "1959" argument is a contrived afterthought. In any event, the court's analysis covered the full history of the combination from prior to 1959 to date, and its effect on competition throughout that period. There was no obscuring of "the real competitive potentialities cut off by the acquisition," for the record demonstrated the contrary. Not only did the affiliation with Freeman launch United Electric on a vigorous (though admittedly unsuccessful) coal reserve exploration program, provide it with access to deep mining experience and know how, but United Electric's competitive potential was actually prolonged beyond what it would otherwise have been. As the District Court found, *"United Electric's existing contracts with Central Illinois Light Company, Northern States Power, and Union Electric are backed up by the reserves of Freeman and could not have been obtained without that guarantee"* (App. 63a, emphasis in original; see also DPF 443-445).[35]

In sum, if there were any competitive potentialities of United Electric that were "cut off," it was *prior to* 1959 and at the hands of its prior management.

[35] As was candidly stated by the government in its Response to Defendant's Proposed Findings (p. 24): "The Government admits the record shows that possibly in three instances, UEC would not have been awarded a particular coal contract without committing some Freeman reserves to the contract. . . ."

CONCLUSION

The motion to affirm should be granted.

Respectfully submitted,

OCTOBER TERM, 1972

No. 72-402

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, AND FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

BRIEF FOR THE UNITED STATES IN OPPOSITION TO MOTION TO AFFIRM

F.2d 11/2/72

Appellees suggest that there are no substantial questions for this Court because (1) the lower court's market definitions, even if erroneous, were immaterial to its conclusion that the Freeman-UEC combination had no anticompetitive effect and (2) UEC's "terminal condition" precludes the possibility of any such effect. However, the court's finding of a lack of anticompetitive effect was based squarely on its acceptance of the appellees' proposed geographic markets, and the

487-566—72

record shows that UEC was far from moribund at the time of its acquisition.

1. Although the district court did say it would have found that no substantial lessening of competition resulted from the Freeman-UEC combination even if it had accepted the government's geographic markets (J.S. App. 59a–60a), the court's subsequent discussion of competitive effects (J.S. App. 60a–64a) was based upon its acceptance of "[t]he Freight Rate Districts in which the mines and reserves of United Electric [as] * * * separate and distinct [geographic] markets from those in which the mines of Freeman are located" (*id.* at 62a).

Appellees quote the lower court's alleged holding that there would be no Section 7 violation "even were this court to accept the Government's unrealistic product and geographic market definitions" (Motion to Affirm, p. 2; J.S. App. 66a). The court's full statement, however, was: "nor would divestiture benefit competition even if this court were to accept the Government's unrealistic product and geographic market definitions" (J.S. App. 66a). The ruling, therefore, was not with respect to the Section 7 violation, but with respect to whether the normal relief for such violation would here "benefit competition." As we have argued, one of the lower court's errors was its attempt to assess Section 7 violations by evaluating the "benefit[s]" of "divestiture" (J.S. 20–22).

The suggestion that the decision below accords with *Kennecott Copper Corp.* v. *Federal Trade Commission*, 5 Trade Reg. Rep. (1972 Trade Cas.) ¶74,157 (C.A. 10), petition for certiorari pending, No. 72–637

demand increases and more easily extractable coal

(Motion to Affirm, p. 11), is unfounded. The court of appeals not only rejected Kennecott's contention that the energy market rather than the coal market should have been adopted to assess the effect of the merger of a coal company and a potential entrant into the coal industry, but also concluded that interfuel competition has no significant effect upon coal prices in the national market. *Id.* at p. 92,840. Interfuel competition has even less impact in coal producing regions than in the nationwide market adopted in *Kennecott*.

2(a). In their attempt to portray UEC as a dying company, appellees dismiss UEC's reserve holdings and other uncommitted coal deposits in the Eastern Interior Coal Province as not "economically mineable" (Motion to Affirm, pp. 26, 33). But what is not economically mineable today may become so tomorrow. Reserves which cannot profitably be mined at one time may become economically mineable at a later time as it becomes exhausted. Thus when Mr. Organ testified that by 1960 there was no available economically mineable strip coal left in the area (Motion to Affirm, p. 33), he had in mind a maximum overburden ratio of 20 to 1[1] (Organ Dep. 111–112). At the time of trial, however, there were four strip mines in the Eastern Interior Coal Province operating at a greater average overburden ratio (DX 49) and another mine being developed which would have a 35 to 1 overburden ratio (Tr. 1980–1982).

[1] The overburden ratio expresses the number of cubic yards of overburden which must be removed to uncover a ton of coal (J.S. App. 16a, n. 17).

This limited view of what constitutes economically mineable reserves underlies appellees' claim that "vigorous efforts were commenced to acquire additional reserves" under their management (Motion to Affirm, p. 33). The testimony of UEC officers that the post-1959 management attempted to acquire "satisfactory reserves, mineable and merchantable, and capable of making a profit" (Camicia Dep. 196) does not mean that UEC attempted during the 1960's to acquire reserves for long-term development. UEC failed to acquire additional reserves after 1959 because it only attempted to acquire reserves which could be profitably developed in the near future. This is confirmed by a 1960 Board meeting at which the directors "decided not to pursue an aggressive purchasing policy" in the Industry Field area because "development of this field is probably some 10 years in the future * * *" (GX 201, p. 4023).

An Ayrshire executive testified that Ayrshire did acquire strip reserves in Illinois and Indiana after 1960 and that other coal producers had also done so (Tr. 1867–1869).[8] The Belle Rive field which UEC decided not to acquire in 1963 or 1964 (Inman Dep. 82–88) was being developed by another company at the time of trial (Tr. 1911). Commonwealth Edison was in the process of acquiring extensive central Illinois strip

[8] He also testified that his company was actively prospecting for strip reserves in Illinois, Indiana and western Kentucky (Tr. 1914). Thus the industry apparently did not share Mr. Organ's conviction (Motion to Affirm, p. 33) that, by 1960, all useable coal strip reserves in the Eastern Interior Coal Province were committed.

reserves at the time of trial which it expected to use (Tr. 1625, 1644, 1667–1668).

(b) The record does not establish that it will be impossible economically to mine any significant portion of the billions of tons of strip reserves in the Eastern Interior Coal Province which remained uncommitted at the time of trial in 1970[3] before UEC's present mines are exhausted.[4] Since appellees' claim that UEC is a self-liquidating company is essentially an affirmative defense, akin to the failing company defense, it was incumbent on them to demonstrate that these reserves will not become economically mineable.

Nor does the record establish that UEC's existing strip reserves in Industry Field cannot be profitably mined in the future. The appellees cite the testimony of Paul Weir, whose company was a litigation consultant for the appellees, that he did not think Industry Field would ever be mined (Motion to Affirm, p. 25).

---

[3] The Illinois State Geological Survey estimated that 19 billion tons of strip reserves remained in the ground in Illinois in 1968 (Simon Dep. Ex. 1, pp. 62–63). In the same year coal producers owned, leased or had optioned approximately 1.78 billion tons of strip reserves in the Eastern Interior Coal Province (DX 62). Appellees have misunderstood the Jurisdictional Statement in assuming that references to other available reserves refer to reserves now owned by UEC rather than uncommitted reserves UEC can acquire (see Motion to Affirm, p. 26).

[4] The district court did not find that such reserves will not be mineable; rather it said that some evidence had been introduced indicating that "economically mineable strip reserves that would permit United Electric to continue operations beyond the life of its present mines are not available" and the government had introduced no evidence that such reserves were "*presently* available" (J.S. App. 63a).

A 1959 asset evaluation report of the Paul Weir Company stated however: "The * * * Industry Field will have substantially higher stripping ratios. In time, competitive conditions will permit their profitable development" (GX Kolbe Dep. Exh. 59, p. 3).[5] Although Mr. Nugent, UEC's president, testified that he no longer believed the field would be mined (Tr. 1946), UEC's officers had always assumed in the past that it would be mined in the future (GX 201, p. 4023; Inman Dep. 162, Nugent Dep. 343–346)[6] and had declined to consider an offer to find another purchaser for the property (Kolbe Dep. 816).

(c) Appellees' present suggestion that UEC's existing reserves in Round Prairie are worthless (Motion to Affirm, pp. 24, 26–29) is similarly based on the assumption that, to have value, reserves must be "economically mineable" presently or in the near future. This is indicated by their reliance on the Government's statement at pretrial that "*as of today* [the reserves] are not commercially valuable" (emphasis added) (Motion to Affirm, p. 24). Appellees never

[5] Their subsequent litigation report cited by appellees as confirming that these reserves "had no promise" (Motion to Affirm, p. 25) describes the reserves as "marginal" and states that the reserves "would not be competitive in the foreseeable future * * *" (DX 37, p. 4).

[6] Appellees claim that Mr. Nugent's deposition testimony "in its entirety" demonstrates that he believed the Industry Field "had no promise" (Motion to Affirm, p. 25, n. 30). We submit, however, that the testimony as a whole indicates that he then expected that the field would be mined after the Fulton County coal is exhausted, but he believed the pre-1959 management should not have paid so much money for a field which will not be mineable until the 1980's.

suggested at trial that UEC's deep reserves in Round Prairie cannot be profitably mined in the future.

The record does not support appellees' suggestion that UEC acquired these reserves for Freeman (Motion to Affirm, p. 27). To the contrary, a UEC director denied that UEC ever planned to "turn over" this corporate opportunity to Freeman (Tr. 893–894).

Appellees apparently rely solely upon Mr. Camicia's statement that he thought it "would be a mistake" for UEC to enter deep mining as establishing that this financially strong company could not do so.[7] Since Mr. Camicia also said that he thought Ayrshire had made a mistake in entering deep mining (Tr. 1426),[8] expressed skepticism as to the wisdom of Humble's venture (Tr. 1424), and testified that he had advised Kennecott that it could only make a successful entry into deep coal mining by acquiring a coal company (Tr. 1395–1396), his testimony merely reflects his view that it would be a mistake for any company to enter deep coal mining. In *Kennecott,* the Federal Trade Commission and the court of appeals held that Kennecott Copper Corporation's acquisition of the Peabody Coal

---

[7] DX 81–83 and the opinion in *United States* v. *Standard Oil Co.* (New Jersey), 253 F.Supp. 196 (D. N.J), merely state that Standard Oil is a very large company with adequate capital to enter potash mining.

[8] Appellees' discussion of Ayrshire's entry into deep mining omits some important facts. The deep mining companies Ayrshire acquired were quite small (Tr. 1869) and Ayrshire did not decide to abandon deep mining when its first venture proved unprofitable. An Ayrshire executive testified that the company expects to mine other deep reserves which it owns (Tr. 1872).

Company, a deep and strip mining company, violated Section 7 because Kennecott was a potential entrant into the coal business by internal expansion or limited acquisition. This suggests that at least one court of appeals would disagree with Mr. Camicia's conclusions respecting the impossibility of a grass roots entry into deep coal mining.

Thus, the record does not establish that UEC was destined to disappear in 1959, or even in 1970. The case thus presents substantial questions for this Court's consideration.

Respectfully submitted.

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, and FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

REPLY BRIEF IN SUPPORT OF THE MOTION TO AFFIRM

Filed 11/2/72

The government's brief in opposition to the Motion to Affirm serves only to demonstrate that the decision below should be summarily affirmed. Discussing but a single case, the government devotes its brief to quarreling with the District Court over the conclusions which it reached on the basis of abundant record evidence. The 7,500 pages of testimony and 10,000 pages of exhibits which formed the substantial evidence upon which the decision below rests can-

not be swept aside, however, by a few fragments of evidence from this massive record. Such an effort to short-circuit the trial record ignores that the question on review in Section 7 cases, as in all other cases, is whether the decision of the trial court is supported by substantial evidence.

At the outset, the government seeks to avoid the District Court's unmistakable holding that the longstanding affiliation of United Electric and Freeman would not violate Section 7 even if the government's product and geographic market definitions were accepted. (App. 59a-60a, 65a-66a.) The government asserts that one of the court's findings in this regard was addressed solely to the question of relief. (Govt. Brief, p. 2.) This argument rests on the government's representation that the "full statement" of the District Court was as follows: "nor would divestiture benefit competition even if this court were to accept the Government's unrealistic product and geographic market definitions." This was hardly the District Court's *full* statement. To the contrary, the court's "full statement" was as follows: "Under these circumstances, continuation of the affiliation between United Electric and Freeman *is not adverse to competition*, nor would divestiture benefit competition even were this court to accept the Government's unrealistic product and geographic definitions." (App. 65a-66a, emphasis supplied.)

The government's attack on a second holding by the District Court that it would have found no substantial lessening of competition if it had accepted the government's geographic markets (App. 59a-60a) rests on a similarly heavy-handed editing, as well as a misreading, of the trial court opinion. The court's own discussion of the likely competitive effects of the combination (App. 60a-64a) makes clear that *none* of its findings with respect to concentration, competitive overlap, types of mining, types of coal, Commonwealth Edison, United Electric's inability to serve Chicago, United Electric's "singularly unpromising" coal reserve prospects and the like were dependent upon the

geographic markets chosen by the court or would have been different had the markets urged by the government been adopted.

Indeed, the government does not and cannot point to a single specific finding in the court's entire opinion that hinged upon resolution of this issue. As to the trial court's finding (unedited here) that "[t]he Freight Rate Districts in which the mines and reserves of United Electric are located serve separate and distinct markets from those in which the mines of Freeman are located" (App. 62a.), this was not addressed to the subsidiary *legal* question of the appropriate "section of the country" but to what the *facts* of record showed with respect to the marketing of coal. Whether it is technically correct to say that United Electric and Freeman serve separate markets within a "section of the country" or to say that they serve separate "sections of the country," there can be no escaping these hard facts showing that "an independent United Electric would not and could not compete with Freeman to any substantial degree." (App. 61a.)

Neither the government's editing nor its arguments can obscure the fact that the subsidiary questions of market definition did not control the District Court's ultimate conclusion that the challenged combination does not violate Section 7. Since these subsidiary questions were neither material to the decision below nor involved any break with precedent, they clearly raise no substantial questions requiring review by this Court.

Nor can the government, by grasping at evidentiary fragments in a record of immense proportions, escape the substantial evidentiary support for the District Court's conclusion that "virtually all of the economically mineable strip reserves of United Electric have been sold under long-term contracts, and United Electric has neither the possibility of acquiring more nor the ability to develop deep coal reserves." (App. 65a.) While the government pretends that the appellees "apparently" rely "solely" upon the testimony of Mr. Camicia with respect to United Electric's lack of any

deep mining potential (Govt. Brief, p. 7), and that of Mr. Organ with respect to the non-availability of strip reserves (*id.* p. 3), appellees, of course, do no such thing. Like the District Court, appellees rely on all of the evidence on these issues provided by a host of witnesses and exhibits.

Just how overwhelming this evidence is may be seen by contrasting the arguments in the government's present brief with the testimony of the only witness called by the government to testify at trial concerning these issues, Mr. Hopper of Ayrshire Collieries:

1. While the government would have this Court believe that there is an abundance of strip reserves available to United Electric (Govt. Brief, p. 5), government witness Hopper verified that "it is common knowledge within the coal industry that strip reserves available for acquisition are in extremely short supply. . . ." (Hopper Tr. 1892.)[1]

2. Though the government chides United Electric for failing to acquire the Belle Rive and Edison properties and claims that United Electric's post-merger management was generally lax in its reserve acquisition efforts (Govt. Brief, p. 4), its witness Hopper testified that his own company

[1] The Court should not be misled by the government's citation to the data of the Illinois State Geological Survey. Mr. Simon, the Principal Geologist of the Illinois State Geological Survey, testified at trial that, by itself, this data "certainly couldn't be used to support" the government's contention that United Electric will be able to acquire additional economically mineable strip reserves in Illinois to continue its mining operations beyond the time when its existing strip reserves are exhausted. (Simon Tr. 62-63; see also Simon Tr. 45.) Indeed, even the government's own economist conceded in the closing days of the trial that the "record indicates that high quality strip reserves are relatively scarce in Illinois." (Folsom Tr. 2476.) Summing up the trial record on this issue, the District Court stated that "[e]vidence was presented at trial by experts, by state officials, by industry witnesses and by the Government itself indicating that economically mineable strip reserves that would permit United Electric to continue operations beyond the life of its present mines are not available." (App. 63a.)

and others had passed up these same properties as having no potential (Hopper Tr. 1881, 1885) and that United Electric's exploration activities in these areas were "a clear indication that they were attempting to find and presumably acquire additional reserves." (*Id.* 1886.)[2]

3. While the government would like to dismiss the expert report and judgment of the mining engineering firm of Paul Weir Company with respect to the lack of competitive potential of the Industry Field,[3] the lack of available midwest strip reserves and United Electric's inability to undertake deep mining (DX 87) as a "litigation report" prepared by a "litigation consultant" (Govt. Brief, pp. 5-6), government witness Hopper acknowledged that the "Paul Weir Company is one of the world's most widely known and highly regarded mining engineering companies" and went on to vouch for its "very fine reputation." (Hopper Tr. 1894.)

---

[2] The record is totally at odds with the government's intimation that United Electric was somehow held back in its reserve acquisition efforts. Mr. Camicia testified that while he was president of United Electric he had a "blank check" to acquire whatever strippable reserves could possibly be found. (Camicia Tr. 1399.) Similarly, Mr. Inman, who had been United Electric's Vice President of Operations, stated that he had had an "open book" with respect to the expenditure of funds on the acquisition of coal reserves (Inman Dep. 205; see also Morris Tr. 536.) The wide latitude which United Electric's personnel were given in their search for additional strip reserves was emphasized by Mr. Camicia at trial: "I didn't even put any reservations on it. I just said find some coal that could be stripped, and then I would decide whether it was worth buying or not. Anything that can be stripped, just so it is black." (Camicia Tr. 1440.)

[3] As the government well knows, the Paul Weir testimony fully detailed the reasons why the 1959 hopes that competitive conditions would in time permit the profitable development of the Industry Field were never realized. Mr. Weir explained that because of the unfavorable profit experience at other mines in the area, changes in the competitive situation in the coal fields and other factors, "the picture is still dark for development of Industry." (Weir Dep. 138-39.) "The coal industry today is not the same coal industry that we had ten years ago, and we have learned certain things about mining in this area, and these cannot help but be reflected in our thinking. . . ." (*Id.* 144.)

4. The government criticizes Mr. Camicia for his belief that Ayrshire had made a mistake in entering deep mining and suggests that United Electric would have no trouble doing so. (Govt. Brief, p. 7.) Government witness Hopper, however, testified that if Ayrshire had it to do over again it would "absolutely not" open its Thunderbird deep mine (Hopper Tr. 1881) and that United Electric "would be in a very awkward position" were it to attempt underground mining. (*Id.* Tr. 1903.)

5. Finally, the government's rose-colored vision of what the future would hold for an independent United Electric also stands in sharp contrast to the views of its witness Hopper. When asked during cross examination whether, in his professional opinion, it would be a mistake to force a company in United Electric's condition to operate independently in the belief that strip reserves were available which would enable the company to remain in business in the future at its current levels of production, Mr. Hopper responded: "Well, it would be my opinion that they would be in a very poor position to live up to the situation that they had been placed in, because I very seriously doubt that they could acquire additional reserves to that extent to maintain that sort of production over a prolonged period of time." (Hopper Tr. 1902.) In view of such testimony *from the government's own witness,* it is not surprising (let alone reversible error) that the District Court rejected the suggestion that it resurrect an independent United Electric whose future prospects were tied to nothing more than the unschooled speculations of government counsel below—repeated here (Govt. Brief, p. 3)—that "what is not economically viable today may become so tomorrow." The District Court quite properly preferred the considered opinions of geologists, mining engineers, experts, state officials, coal consumers, and coal producers who had spent their life-

time in the coal business to such *ipse dixit* forecasts by attorneys whose experience in the field began with this litigation.

The testimony of the government's only witness on these issues was thus squarely against it, and corroborated the record evidence introduced by defendants on these same issues from dozens of witnesses and scores of exhibits. There can be no doubt then that the trial court's opinion is supported by substantial evidence and would not be reversed upon a plenary review.

Try as it may, there is simply no way the government can overcome the fact that the decision below turned on the resolution of a host of complex and disputed *evidentiary* issues peculiarly within the province of the trier of fact. Since the decision below was clearly correct, involved no departure from existing Section 7 precedent, and presents no legal issues that were either material or substantial, the decision below should be summarily affirmed.

Opinion below	1
Jurisdiction	1
Questions presented	2
Statute involved	2
Statement	3
A. The coal industry	3
B. The acquiring company—General Dynamics, Material Service, and Freeman	7
C. The acquisition and the acquired company (United Electric)	8
D. Competition between the acquiring and the acquired companies	11
E. The proceedings below	11
Summary of argument	13
Argument:	
I. Coal is an appropriate line of commerce for determining the competitive effects of the acquisition	20
A. Coal satisfies Brown Shoe's "practical indicia" of an "economically significant submarket"	21
1. Coal is recognized as a separate economic entity	21
2. Coal has peculiar characteristics and uses	22
3. Coal has unique production methods and facilities	22
4. Coal has distinct prices	24

495-300—73——1

Argument—Continued

Page

5. Coal has distinct customers and its prices are relatively insensitive to changes in the price of other fuels.... 25

B. The district court's conclusion that energy is the exclusive relevant line of commerce rested upon a misunderstanding of *United States* v. *Continental Can Co.*, 378 U.S. 441.. 33

II. Illinois and the Eastern Interior Coal Province sales area are appropriate sections of the country for determining the competitive effects of the acquisition..... 35

A. The geographic markets proposed by the government correspond to the realities of the coal industry and are economically significant..... 36

1. The Eastern Interior Coal Province sales area is a relevant section of the country..... 37

2. Illinois is a relevant section of the country..... 39

3. The district court erred in rejecting these areas as relevant sections of the country..... 42

B. The geographic markets the district court adopted are improper, but in any event they do not negate the broader markets of Illinois and the Eastern Interior Coal Province sales area..... 44

Argument—Continued Page

III. The effect of the acquisition may be substantially to lessen competition in the relevant markets 50

A. A horizontal merger is illegal under Section 7 if it significantly increases concentration in a concentrated market 50

B. Under these criteria the Freeman-United Electric combination is unlawful 54

1. The market is concentrated and the trend is toward further concentration 54

2. The merger is *prima facie* unlawful because it produces a firm with an undue percentage share of these concentrated markets and significantly increases concentration there 57

C. The acquisition is also illegal because it eliminates substantial competition between Freeman and United Electric 60

D. The merger cannot be justified on the ground that, because of inadequate reserves, United Electric no longer was a significant competitive factor in the coal business 63

1. The claim that the merger would not substantially lessen competition because the acquired company had "inadequate resources" to remain a significant competitor must be tested by the general legal standards that govern the "failing company" defense 63

Argument—Continued Page

2. The district court did not find, and the record does not show, that at the time of the acquisition United Electric was about to go out of business and could not be rehabilitated 70

Conclusion 75

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, AND FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

BRIEF FOR THE UNITED STATES

OPINION BELOW

The opinion of the district court (J.S. App. 1a–66a) is reported at 341 F. Supp. 534.

JURISDICTION

The opinion and judgment of the district court was filed on April 13, 1972. The notice of appeal to this Court (J.S. App 67a–68a) was filed on June 7, 1972. Probable jurisdiction was noted on December 11, 1972. The jurisdiction of this Court rests on Section 2 of the Expediting Act (15 U.S.C. 29). *United States* v. *El Paso Natural Gas Corp.*, 376 U.S. 651.

QUESTIONS PRESENTED

1. Whether, under Section 7 of the Clayton Act, coal is a relevant line of commerce for determining the competitive effects of the combination of two coal producers, who were the second and fifth largest coal producers in Illinois and the second and sixth largest in the Eastern Interior Coal Province sales area.

2. Whether Illinois and the Eastern Interior Coal Province sales area are relevant sections of the country for determining the competitive effects of such a combination.

3. Whether, in this line of commerce and in these sections of the country, the effect of the combination may be substantially to lessen competition.

4. Whether the district court applied an erroneous legal standard in ruling that the merger would have no anticompetitive effect because, at the time of trial, the acquired company was not a viable competitive force in the market due to its lack of adequate coal reserves.[1]

STATUTE INVOLVED

Section 7 of the Clayton Act, 38 Stat. 731, as amended, 64 Stat. 1125, 15 U.S.C. 18, provides in pertinent part:

> No corporation engaged in commerce shall acquire, directly or indirectly, the whole or any part of the stock or other share capital and no corporation subject to the jurisdiction of the Fed-

[1] This question is a revision of the fourth question presented in the jurisdictional statement. The focus has been shifted from the evidentiary support for the finding to its legal sufficiency as a basis for concluding that the merger would have no anticompetitive effect. The latter issue was raised in both the jurisdictional statement and the brief in opposition to the motion to affirm. See note 47, *infra*, p. 70.

eral Trade Commission shall acquire the whole or any part of the assets of another corporation engaged also in commerce, where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition, or to tend to create a monopoly.

* * * * *

STATEMENT

The United States instituted this civil antitrust case, charging that the acquisition of the stock of United Electric Coal Companies ("United Electric"), by Material Service Corporation ("Material Service") and its successor, General Dynamics Corporation ("General Dynamics"), violated Section 7 of the Clayton Act (15 U.S.C. 18). It alleged that actual and potential competition in the Illinois and Eastern Interior Coal Province sales area coal markets may be substantially lessened by the acquisition. After a trial on the merits, the district court held there was no violation.

A. THE COAL INDUSTRY

The coal industry has undergone a substantial transformation since the Second World War. It lost the railroad market entirely to diesel fuel. It lost most of the home heating market and a substantial portion of the industrial market to gas and oil (J.S. App. 11a–12a). From 1947 to 1954, total coal production in the United States decreased more than a third.[2] Since

[2] Production was 441 million tons in 1947 and 278 million tons in 1954 (DX 85, A. Ex. 657). The appendix volumes containing exhibits have been separately paginated. "A. Ex." references are to the exhibit volumes. "A." references are to the other appendix volumes.

1954 the electric utility market has become the mainstay of the coal industry, accounting by 1968 for 71 percent of the national coal consumption (DX 85, A. Ex. 657).

This change in markets has not, however, led to the disappearance of the coal industry. On the contrary, the utilities' rapidly increasing energy demands have stimulated a resurgence of coal production since the low point of 1954. By 1968, United States coal production was up nearly to the 1947 level (DX 85, A. Ex. 657), and the Bureau of Mines estimates that production will continue to increase at the rate of 3.1 percent per year through 1980 (GX 232, A. Ex. 152).

Coal usage by electric utilities varies among different areas of the country. Utilities on the east and west coasts use substantial amounts of oil, but almost no oil is used in the interior of the country. Natural gas is used in most states west of the Mississippi, and is the principal fuel for utilities in the southwest and south central states; but very little gas is used east of the Mississippi. Coal is the dominant fossil fuel[3] for utilities east of the Mississippi and south and west of New York, and it supplies more than half of the requirements of utilities in the New York-New England, west north-central, and mountain areas.[4]

---

[3] Fossil fuels are hydrocarbon energy sources which have been mineralized through geological ages and are extracted from the earth. They include various forms of coal, natural gas, and petroleum.

[4] In 1966 oil accounted for 18 percent of the BTUs of fossil fuel consumed by utilities in the Pacific Coast area, 12 percent in the South Atlantic area, 21 percent in the Mid-Atlantic area, 42 percent in the New England area, and

Bituminous coal is found in four major producing areas in the United States. The area involved in this case—commonly known as the Eastern Interior Coal Province (A. 680–681)—is composed of the central and southern two-thirds of Illinois and much of southwestern Indiana and western Kentucky. The other areas are: the Appalachian or Eastern Coal Province, encompassing Pennsylvania, West Virginia, eastern Kentucky, and parts of Ohio, Tennessee, and Alabama; the Western Interior Coal Province, comprising parts of Iowa, Kansas, Missouri, and Oklahoma; and the Western Province, consisting of scattered deposits in Montana, Wyoming, Colorado, and Utah (Kurtz Dep. Ex. 10, A. Ex. 1657.) (Anthracite and lignite coal deposits, which are not involved in this case, are respectively located east of the Appalachians and in Montana and the Dakotas. *Ibid.*)

High transportation costs, which may approach 30 to 40 percent of the delivered price of coal (J.S. App. 57a), tend to insulate coal producers in one producing area from competition from mines in other producing areas. Although the Eastern Interior Coal Province produced approximately one-fourth of the coal sold in

---

less than 2 percent in each of the interior states except Utah and Montana. Natural gas accounted for more than 90 percent of the BTUs consumed by utilities in Kansas, Oklahoma, Arkansas, Texas, Louisiana, and Mississippi, and more than 80 percent in California and Arizona, but it represented less than 6 percent of the BTUs consumed by utilities east of the Mississippi River. Coal accounted for more than 90 percent of the BTUs consumed by utilities in all the states east of the Mississippi and south or west of New York except New Jersey, Delaware, South Carolina, Florida, and Mississippi. (Kurtz Dep. Ex. 10, A. Ex. 1658–1659.)

the United States in 1967, coal from that area did not account for any of the reported sales in the northeast and far west and accounted for less than 10 percent of coal sales even in the relatively nearby states of Michigan and Ohio. At the same time, more than 90 percent of the non-metallurgical coal [5] sold in Indiana and Illinois and more than half of that sold in Minnesota, Wisconsin, Iowa, Missouri, and Kentucky was produced in the Eastern Interior Province (Gallagher Dep. Ex. 3, A. Ex. 1424–1447).

All of the mines of the acquired and acquiring companies are located in Illinois within the Eastern Interior Coal Province, where the leading producers have accounted for an ever-increasing share of the coal production. The following table shows the increase in the percentage shares of coal production by the leading producers in a recent 10-year period:

	Eastern Interior Coal Province		Illinois	
	1957	1967	1957	1967
Top 2 firms	29.6	43.6	27.8	32.9
Top 4 firms	43.0	62.9	34.5	75.2
Top 10 firms	65.5	91.4	84.0	98.0

This period was also marked by a sharp decline in the number of producers. Although 144 companies were producing coal in the Illinois portion of the producing area in 1957, only 39 companies remained in 1967 (GX 73, A. Ex. 92).

[5] Metallurgical coal is used in coke production for metallurgical purposes. Illinois mines produce only 4 million tons of such coal annually out of a total production of almost 65 million tons (GX 210, A. Ex. 135). Coal used for all other purposes is termed nonmetallurgical coal.

B. THE ACQUIRING COMPANY—GENERAL DYNAMICS, MATERIAL SERVICE, AND FREEMAN

General Dynamics is a large and diversified company; it ranked 27th among industrial corporations in the United States in 1968, with total sales of more than $2.6 billion (*Fortune Magazine,* May 15, 1969, p. 168). It became the Nation's fifth largest coal miner as a result of its acquisition in 1959 of Material Service, which was then engaged in producing and supplying building materials, coal, and limestone (J.S. App. 2a–3a). Material Service had, since 1942, owned all of the capital stock of Freeman Coal Mining Corporation ("Freeman") (J.S. App. 3a, 4a).

Freeman's mining operations have always been centered in southern Illinois. It operated three mines in that area at the time this action was filed and had opened a fourth by the time of trial. It also operated the Crown Mine in central Illinois. All of the Freeman mines are deep mines. (J.S. App. 4a, 6a.)

In 1959 Freeman produced 6.9 million tons of coal—approximately 15 percent of Illinois production (GX 64, A. Ex. 83) and 8 percent of Eastern Interior Coal Province production (GX 77, A. Ex. 96). It was the second largest producer in each area. In 1967 it produced 8.4 million tons—approximately 13 percent of Illinois production (GX 72, A. Ex. 91) and 6 percent of Eastern Interior Coal Province production (GX 85, A. Ex. 98). Freeman's production is 92 percent nonmetallurgical coal (A. 1529–1530). At the time of trial it controlled approximately 484 million tons of deep coal reserves in Illinois (DX 61, A. Ex. 577).

C. THE ACQUISITION AND THE ACQUIRED COMPANY (UNITED ELECTRIC)

Material Service began acquiring United Electric stock in 1954 and had increased its holdings to 34 percent by 1959 when Freeman's president, Frank Nugent, was elected Chairman of United Electric's Executive Committee (J.S. App. 7a–8a). General Dynamics acquired Material Service a few months later and continued to acquire United Electric stock. General Dynamics had increased its holdings to 66 percent of United Electric's stock by September 1966, when it made a successful tender offer for the remaining shares. United Electric became a wholly-owned subsidiary of General Dynamics at the beginning of 1967. (J.S. App. 8a–9a.)

United Electric has operated mines in various parts of Illinois and western Kentucky since it was formed in 1919. At the beginning of 1959 it operated one mine in Kentucky and four in Illinois, and at the time of trial it was operating only four in Illinois. All of these mines were open pit or strip mines; United Electric has not operated a deep mine of any kind since 1954. (J.S. App. 6a–7a.)

From at least 1955 through the time of trial United Electric has been a healthy company with a good financial record and a secure future. It has been one of the leading coal producers in the Eastern Interior Coal Province, and its production increased from 3.6 million tons in 1957 to 5.7 million tons in 1967 (GX 62–72, A. Ex. 81–91). This average annual growth rate of 5.1 percent is higher than the average for producers in the State of Illinois (3.4 percent) and in the Province as a whole (3.6 percent) (DX 87, A. Ex. 783, GX 86, A. Ex. 100). During a comparable period,

United Electric's share of the total State and Province production remained relatively stable. In 1959 it accounted for 8.1 percent of Illinois production and 4.8 percent of Province production (GX 64, A. Ex. 83, GX 77, A. Ex. 77); in 1967 the figures were 8.9 percent and 4.4 percent (GX 72, A. Ex. 91, GX 85, A. Ex. 98).*

United Electric has consistently had one of the highest profit margins in the coal industry. It led the industry in operating income as a percentage of revenues in 9 out of 11 years from 1955 through 1965, as shown in a Standard & Poor's survey of 13 major coal companies (GX 26, A. Ex. 24). From 1959 through 1967, the company had total profits of $24.1 million on sales of $181.2 million (GX 25, A. Ex. 12). Freeman had profits of $15.8 million on sales of $289.9 million during the same period (Nugent Dep. Exs. 1–9, A. Ex. 1741–1763).

In 1959, United Electric had a net worth of $19.6 million, working capital of $2.8 million, and long-term debt of $1.2 million (GX 24, A. Ex. 11). By 1968, despite the payment of $11 million in dividends to General Dynamics (Nugent Dep. Ex. 22, A. Ex. 1774–1775, GX 27, A. Ex. 29–31), United Electric had eliminated all its long-term debt, had increased its net worth to $26.9 million, and had accumulated $10.7 million in working capital (GX 34, A. Ex. 41).

In 1970, United Electric owned or leased an estimated 52 million tons of strip reserves in its existing mines (J.S. App. 9a). Assuming that no other reserves

* In 1959, United Electric was the fifth largest producer in the State and the sixth largest in the Province; in 1967, it was sixth in the State and ninth in the Province (GX 64, A. Ex. 83, GX 72, A. Ex. 91, GX 77, A. Ex. 96, GX 85, A. Ex. 98).

around these four mines are acquired, the mines would continue as of 1969 to produce at that year's levels for 2, 7, 9, and 16 years, respectively (DX 60C, A. Ex. 544–572, DX 60D, A. Ex. 573).[7] The company also owns 12.6 million tons of strip reserves in a field that contains an estimated 25 to 50 million tons of coal (DX 60A, A, Ex. 517, A. 1142, Morris Dep. Ex. 31, A. Ex. 1686–1687). These reserves will in time be economically mineable (Kolbe Dep. Ex. 59, A. Ex. 1552, GX 201, A. Ex. 133, A. 54–55, 182, 204, but see A. 1528).

Apart from strip reserves, United Electric owns about 44 million tons of deep reserves (DX 60A, A. Ex. 517) and controls by location[8] another 40 to 50 million tons (A. 1055–1056, 1103–1105, DX 60A, A. Ex. 517).[9]

---

[7] The district court found that all but four million tons of the estimated reserves have been committed under long-term contracts (J.S. App. 9a, 65a). The defendants' own exhibit, however, shows that nearly 11 million tons classified by the court as "committed" are committed only to "Current Negotiations" (DX 63, A. Ex. 579). Moreover, most of the actual commitments were made after the acquisition and after this action was filed. United Electric entered into a 20-year contract for approximately 21 million tons in 1968 (A. 1204, DX 35, A. Ex. 262, DX 63, A. Ex. 579).

[8] Reserves contiguous to those owned, leased, or optioned are "controlled by location" if, in order to be mined at all, they must be mined by the holder of the rest of the reserves in the area (A. 87).

[9] While the district court stated that United Electric now lacks the ability to mine these deep reserves (J.S. App. 65a), the company has the financial resources necessary to embark on a deep mining operation, and the court made no finding that the company could not have obtained the necessary expertise had it not been combined with Freeman (see pp. 72–73, *infra*).

D. COMPETITION BETWEEN THE ACQUIRING AND THE ACQUIRED COMPANIES

Both Freeman and United Electric sell coal in Wisconsin, Illinois, Kentucky, Iowa, and Missouri (GX 54–60, A. Ex. 73–79). As shown in the following table, the companies sell about half of their coal to the same customers and most of that is shipped to the same customer facilities (GX 88–91, A. Ex. 107–117):

	Year	Tons sold (thousands)	Percent of total sales to common customers	Percent of total sales to identical customer facilities
United Electric	1965	5,487	70.2	54.7
	1966	4,964	62.1	52.9
	1967	5,914	61.6	48.2
	1968	7,916	51.4	37.4
Freeman	1966	8,582	44.0	37.0
	1967	9,078	42.8	33.8

That Freeman and United Electric are actual and potential competitors was acknowledged by officials of the companies and by customers of each (A. 84, 131, 1437, GX 93, A. Ex. 118–119, GX 94, A. Ex. 121–123, GX 104, A. Ex. 124–125). Freeman and United Electric salesmen solicit many of the same customers (A. 48, 121).

E. THE PROCEEDINGS BELOW

The United States filed its complaint on September 22, 1967. The trial was held from March 30 to April 22, 1970, and the district court issued its opinion on April 13, 1972.

The government's theory was that the United Electric acquisition involved a merger of competing firms. It contended that coal is an appropriate line of com-

merce, and that Illinois and the Eastern Interior Coal Province sales area [10] are appropriate sections of the country in which to assess the competitive effects of the combination. The government's proof was directed to showing that the Freeman-United Electric combination had an inordinate share of those concentrated markets and was likely to produce substantial anti-competitive effects within them.

The district court rejected the government's proposed product and geographic markets. It held, after a lengthy discussion of interfuel competition in the electric utility market, that "the energy market is the appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination" (J.S. App. 53a). It also adopted the geographic markets proposed by the defendants. These consisted of the Commonwealth Edison Company, the Metropolitan Chicago Interstate Air Quality Control Region, and utility and non-utility sales areas for coal mines located in each of four different freight rate districts (J.S. App. 56a-59a).[11]

[10] The Eastern Interior Coal Province sales area—in which Province coal producers sell most of their coal—consists of Illinois, Indiana, the western half of Kentucky, the western one-third to one-half of Tennessee, the extreme eastern portion of Missouri on or near the Mississippi River, the eastern half of Iowa, southeastern Minnesota, and southern Wisconsin (see pp. 38-39, *infra*).

[11] The Interstate Commerce Commission has designated various coal producing areas within Illinois, Indiana, and western Kentucky as freight rate districts (J.S. App. 4a). The normal freight rates are uniform for all mines located in a particular freight rate district.

The district court also concluded that the government had failed "to show that a substantial lessening of competition resulted from the United Electric-Freeman combination" (J.S. App. 60a). The court's conclusion that there was no substantial anticompetitive effect rested on subsidiary findings (a) that United Electric's strip coal reserves are committed and the government did not show that additional economically mineable strip reserves are presently available (J.S. App. 63a), (b) that United Electric did not have the skill to mine its deep reserves (J.S. App. 65a), and (c) that United Electric and Freeman do not compete but are "predominantly complementary in nature" (J.S. App. 61a) because of their different mining techniques, because Freeman produces some dust and metallurgical coal while United Electric does not, because Freeman produces some coal that has a lower sulphur content than United Electric coal, and because Freeman and United Electric mines are located in different freight rate districts (J.S. App. 61a–62a). The court therefore concluded that the United Electric-Freeman affiliation "is not adverse to competition, nor would divestiture benefit competition" (J.S. App. 66a).

SUMMARY OF ARGUMENT

I

A. The district court held that "energy" is the exclusive line of commerce for determining the competitive effects of this combination of two coal companies. Section 7 of the Clayton Act, however proscribes a

merger if it may substantially lessen competition in *any* line of commerce. Even if energy is an appropriate product market, coal satisfies the "practical indicia" of an "economically significant submarket," as defined by this Court in *Brown Shoe Co.* v. *United States,* 370 U.S. 294, 325.

Coal is recognized by the industry, by governmental authorities, and by the public as a separate economic entity. It is physically different from other forms of energy, its heat producing qualities are unique, and it is used for a narrower range of commercial purposes than other fuels. Its mining and production techniques are unlike those for oil, natural gas, and nuclear fuel. In the areas served by Freeman and United Electric, coal is sold at a delivered price per BTU significantly lower than that for competing fuels.

Because of its low price, coal is overwhelmingly preferred as a fuel by those consumers—particularly steam-electric utilities—for whom fuel expenses are the principal cost of doing business. In the areas involved in this case coal has had minimal competition from other fuels for the business of this narrow class of consumers, producing, for example, 90 percent of the BTUs consumed by steam-electric utilities in Illinois. It is likely to maintain its substantial competitive advantage in these areas, where major coal deposits are located.

Just as coal's advantages make it attractive to utilities and other industrial fuel consumers, its commercial and aesthetic disadvantages make it unattractive to other consumers. Highway, air, and rail transporta-

tion are dependent on liquid fuels; consumer preference for gas and oil, despite higher prices in many areas, make coal an ineffective competitor in the space-heating market. Fluctuations in the price of other fuels are not likely to affect the delivered price of coal.

B. The district court's holding that "*the* relevant line of commerce must encompass interfuel competition" (J.S. App. 55a, emphasis added), rests upon a misunderstanding of *United States* v. *Continental Can Co.*, 378 U.S. 441. That case involved a merger of a metal container producer and a glass container producer, and the Court held that, because of the substantial interindustry competition between the two products, the combined metal and glass container industries constituted an appropriate line of commerce. *Continental Can* dealt only with how broadly, not how narrowly, the product market may be drawn. The decision does not imply that, in evaluating a merger between two coal companies, the *only* revelant market must include other competing fuels. Indeed, the Court in *Continental Can* recognized that, in addition to the combined glass and metal market, each of those industries separately would be an appropriate product. Here, too, regardless of whether energy may be a relevant line of commerce, coal is an appropriate submarket.

II

A. The government showed that the United Electric-Freeman combination may substantially lessen competition in two sections of the country—the Eastern Interior Coal Province sales area and the State of

Illinois. Each corresponds to the competitive realities of the coal industry, and each is an appropriate geographic market.

There are four major coal producing regions or provinces in the country, and producers in one tend to be insulated from competition by producers in another. Because of transportation costs, which may be 30 to 40 percent of the delivered price of coal, the competitive sales area for producers within a region generally conforms to the geographic range beyond which the delivered price is higher than that for coal originating in another province. The Eastern Interior Province, where all the Freeman and United Electric mines are located, is a geographically distinct coal producing region, and producers there enjoy a competitive advantage over producers in other provinces with respect to sales in an identifiable area comprising Illinois and Indiana and parts of Kentucky, Tennessee, Iowa, Minnesota, Wisconsin, and Missouri. Nearly all the coal used by steam-electric utilities in this sales area is produced in the region, and more than 80 percent of the coal produced in the region is consumed in the sales area. Freeman and United Electric sell almost all their coal to customers in the sales area, and each has shipped coal to almost every State within the area.

Within this broader market, Illinois is an appropriate submarket. The State has been a separate mining district under the Bituminous Coal Act of 1937, its production figures are separately reported by the Bureau of Mines, and all the Freeman and

United Electric mines are located within its boundaries. Illinois consumers buy most of their coal from Illinois producers (90 percent in the case of utilities), and Illinois mines sell most of their coal (about 60 percent) to Illinois customers. Freeman and United Electric sell more coal in Illinois than in any other State.

B. Appellees' ten geographic markets, which the district court adopted, do not reflect the competitive realities of the coal business. Instead of focusing on the area of competitive overlap between Freeman and United Electric in which the impact of the acquisition would be most direct and immediate, the district court erroneously adopted geographic markets that ignore the areas of competitive overlap.

In any event, Section 7 proscribes mergers with anticompetitive effects in *any* section of the country. Even if the district court's geographic markets were appropriate, they do not negate the existence of one or more broader markets—here, the Province sales area and Illinois—within which the combination may substantially lessen competition.

III

A. Under Section 7 a horizontal merger is *prima facie* unlawful if it produces a firm controlling an undue percentage share of the market and significantly increases concentration in the market. While no specific percentage share is necessarily "undue," this Court has applied the principle of *prima facie* illegality in mergers involving combined shares as small as

4.5 percent, 7.5 percent, and 11 percent, where concentration in the relevant markets had been rapidly increasing.

B. In both the Eastern Interior Coal Province and the State of Illinois, concentration levels prior to the 1959 acquisition were greater than the pre-merger levels in markets this Court has considered sufficiently concentrated to bar mergers producing relatively small combined shares. Between 1957 and 1967 the concentration levels in those areas rapidly increased while the number of producers in Illinois decreased from 144 to 39. The acquisition of United Electric, whether viewed as of 1959, when Material Service took control, or as of 1967, when General Dynamics became the sole shareholder, brought together two of the leading producers in each of these concentrated markets. The combined shares of coal production in the Province (12.4 percent in 1959) and Illinois (23.2 percent in 1959) exceed or approach the shares this Court has held *prima facie* unlawful for concentrated markets. Moreover, the acquiring company significantly increased its share of the markets, and the acquisition resulted in substantial increases in market concentration.

C. Apart from this structural data showing that the acquisition resulted in an undue combined percentage share of the relevant markets, the combination eliminated substantial direct competition between Freeman and United Electric. The companies sell about half their coal to common customers, and most of those sales are to identical customer facilities. Salesmen of the companies solicit the same customers.

D. The district court held, however, that the merger would have no anticompetitive effect because United Electric's coal reserves were so inadequate that the company could not continue as a viable competitor in the market. This claim of inadequate resources rests on the same economic premise as the "failing company" defense—that elimination of a firm does not substantially lessen competition if the firm would not otherwise have been a viable enterprise. Although an "inadequate resources" defense requires a different factual showing, it must be tested by the same general legal standards applied in failing company cases.

A failing company defense requires a showing that, prior to the acquisition, every reasonable method of economic rehabilitation was explored but found unavailable and that the acquiring company was the only available purchaser. Similarly, in the case of an extractive industry, a defense based on the claim that the acquired company's resources were virtually exhausted requires a showing that there was no alternative method of prolonging the company's life, including sale to other purchasers.

This Court has recognized that the validity of a failing company defense must be determined as of the time of the acquisition, not the time of trial. The district court's findings with respect to United Electric's lack of coal reserves do not sustain an "inadequate resources" defense because they do not relate to United Electric's viability in 1959, when Material Service took control of the company, or in 1967, when General Dynamics became the sole shareholder. There is no finding, and the record does not show, that United

Electric's reserves in 1959 or 1967 were so depleted that the company was about to go out of business; that United Electric could not have acquired additional strip reserves after 1959 or 1967; or that United Electric could not have acquired deep-mining expertise if it had not become affiliated with Freeman (a deep mining company). It is unlikely that a firm as large and successful as United Electric would have allowed its coal business to disappear. Moreover, there is no finding that United Electric explored other less anticompetitive means of solving its reserve problems. In particular, the record does not establish that Material Service was the only available purchaser with access to additional coal reserves.

ARGUMENT

I

COAL IS AN APPROPRIATE LINE OF COMMERCE FOR DETERMINING THE COMPETITIVE EFFECTS OF THE ACQUISITION

The district court held that "the energy market is the appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination" (J.S. App. 53a). A merger violates Section 7 of the Clayton Act, however, if it has the proscribed anticompetitive effect "in any line of commerce." The proper inquiry in determining the market in this case, therefore, is not whether the energy market is "the" appropriate line of commerce, but whether coal is "an" appropriate line.

There may well be an energy market that would be an appropriate line of commerce for testing the com-

petitive effect of a merger between companies operating in different segments of that market. Cf. *United States* v. *Continental Can Co.*, 378 U.S. 441. But the possibility of that broader market is not inconsistent with and does not negate the existence of a narrower coal market as an appropriate line of commerce for determining the validity of a merger between companies engaged solely in that business. For "within this broad market, well-defined submarkets may exist which, in themselves, constitute product markets for antitrust purposes" (*Brown Shoe Co.* v. *United States*, 370 U.S. 294, 325). Coal is such a submarket.

A. COAL SATISFIES BROWN SHOE'S "PRACTICAL INDICIA" OF AN "ECONOMICALLY SIGNIFICANT SUBMARKET"

The Court in *Brown Shoe* stated (*ibid.*):

> The boundaries of such a submarket may be determined by examining such practical indicia as industry or public recognition of the submarket as a separate economic entity, the product's peculiar characteristics and uses, unique production facilities, distinct customers, distinct prices, sensitivity to price changes, and specialized vendors. * * *

A realistic appraisal of these "practical indicia" of a discrete product shows that coal is an "economically significant submarket" (*ibid.*) for purposes of Section 7.

1. Coal is recognized as a separate economic entity.

Coal is classified as a separate industry by the Office of Management and Budget (GX 29, A. Ex. 34). The industry has its own trade associations, labor

unions, and trade publications (A. 140). Federal and state agencies and various trade associations publish separate statistics on coal reserves, coal production, and coal shipment (see, *e.g.*, Gallagher Dep. Ex. 3, A. Ex. 1416–1455, Simon Dep. Ex. 1, A. Ex. 1810–1820, Terleke Dep. Ex. 11, A. Ex. 1841–1845).

2. Coal has peculiar characteristics and uses.

A lump of coal is quite different from any comparable unit of oil, uranium, or natural gas. The equipment necessary for burning coal differs from that for other fuels (See DX 150, A. Ex. 1110). Coal's thermal efficiency differs from that of other fuels (*ibid.*).[12] While the various fuels have generally similar end uses—the generation of energy or production of heat—because of coal's special advantages and disadvantages it is used principally by electric utilities and other industries in which fuel is a major cost factor; unlike gas and oil, coal is now rarely used for space heating or by the transportation industry (see pp. 25–27, *infra*).

3. Coal has unique production methods and facilities.

Coal is mined by the strip or open pit method, or by the deep or underground method. In strip mining the dirt, rock, and shale (overburden) overlying the coal seam is removed with large earth-moving machines and the coal is scooped up and hauled away with smaller pieces of equipment. The

[12] In power generation, coal requires between three and five percent fewer BTUs per kilowatt-hour than does gas; oil is less efficient than coal but more efficient than gas (DX 150, A. Ex. 1110).

coal is then sent to preparation plants which size the coal and improve its quality through a washing process (Kolbe Dep. Ex. 2, A. Ex. 1526–1529). There are three types of deep mining—the drift operation (punching or going into the coal seam from a hillside), the slope operation (removing coal by a conveyor belt going underground at 17 degrees or less to fairly shallow depths), and the shaft operation (using a deep vertical shaft through which coal is removed by hoists and skips) (A. 75–76, 1358–1359).

By contrast, natural gas and crude oil are channeled or pumped out of the ground through pipes. Crude oil is broken down into different distillates at highly complex computerized refineries (DX 81, A. Ex. 621, A. 463).[15] Natural gas either travels from the wellhead to the fuel burner through a series of pipelines or is liquified at a liquefaction plant and shipped or stored in tanks (A. 482–483). The production and processing of nuclear fuel is, of course, considerably more complex.[16]

---

[15] Residual oil—the only fuel oil used for electric generation in this country—is an oil-refinery by-product that remains after the more valuable refined liquids have been extracted and solids have been removed (DX 150, A. Ex. 1114).

[16] The nuclear fuel cycle involves the following steps: the ore is subjected to a milling process which increases the concentration of uranium oxide; the concentrate is converted to uranium hexafluoride, which is then enriched in gaseous diffusion plants; the enriched matter is converted to uranium dioxide pellets, which are inserted into specially manufactured zirconium tubing; the tubing is then fabricated into fuel elements which are assembled in the reactor as the core; spent fuel is reprocessed to recover the remaining usable uranium, plutonium, and other valuable isotopes (DX 116, A. Ex. 1043–1057).

4. Coal has distinct prices.

In the areas served by Freeman and United Electric, coal's delivered price per BTU is significantly lower than that for any other combustible fuel except interruptible natural gas, which is available only on a seasonal basis (GX 35, A. Ex. 35, GX 36, A. Ex. 47, GX 37, A. Ex. 53).[15] The president of Central Illinois Light Co., for example, testified that his company purchases coal for 27 cents per million BTUs and buys some refined oil for ignition fuel at 70 cents per million BTUs; the company's lowest firm rate for natural gas is 45 cents per million BTUs (A. 1207, 1210). The witness also testified that coal prices have been significantly lower than gas or oil prices for the last ten years and that he did not expect gas to approach the price of coal in the near future (A. 1209–1210). A cement company official stated that his company did not need to make any formalized surveys in order to determine which fuel to use. A cursory investigation revealed that the cost of coal was substantially less than the cost of gas or oil (GX 43, A. Ex. 63).[16]

---

[15] Gas is supplied at either a firm or an interruptible rate. Firm rate gas is substantially higher in price and approaches the price of purchased electricity (A. 740, 1116, GX 41, A. Ex. 60). Firm rate customers are supplied according to their needs, and they always have priority. Interruptible gas is sold at a lower rate and only when it is not required by firm rate customers (A. 1180–1181). In the midwest, interruptible gas is placed on the market only during the warmer months, and its availability varies among different locations (Morris Dep. Ex. 70, A. Ex. 1713, Kolbe Dep. Ex. 4, A. Ex. 1531, A. 475, 479, 483).

[16] Other witnesses attested to the price differential. A past president of United Electric stated that coal prices have been "much lower" than gas prices, and that United Electric used to sell a ton of coal for about $5 while an equivalent amount of

5. Coal has distinct customers and its prices are relatively insensitive to changes in the price of other fuels.

Coal's commercial advantages and disadvantages in the areas served by Freeman and United Electric make it attractive only to a distinctively limited set of potential customers. Coal is unable to compete for the business of some fuel consumers, but at the same time it has an overwhelming competitive advantage with respect to others. The preferences and requirements of consumers in the relevant geographic areas tend to minimize interfuel price competition, except at the geographic fringes, because price-oriented consumers prefer coal, while those for whom delivered price is secondary generally choose other fuels.

a. As the court below recognized, for many customers factors other than delivered price may control the choice of a fuel (J.S. App. 29a):

> The costs of storing, handling, and in some instances, disposing of the fuel by-products or residue, for example, are economic factors which can make a low-cost fuel the most expensive fuel. These costs become a particularly important consideration in selecting a proper fuel in locations where land costs are high and in heavily congested areas. In some areas, operating considerations, such as air pollution control regulations, may require a premium priced fuel and foreclose consideration of others.

Thus, the technology of highway and air transportation requires the use of liquid fuels, and because of

---

oil was selling for about $8 (A. 140–141). See, also, A. 279–280, 363, 574–575, GX 41, A. Ex. 60, GX 39, A. Ex. 59.

dieselization oil is now the fuel used in rail transportation (DX 102, A. Ex. 944). Simple consumer preference, rather than price, is the controlling factor in the space-heating market, where gas and oil are preferred despite their higher prices (DX 102, A. Ex. 981).

The capital investment in equipment necessary for the burning of coal is 10 to 15 percent greater than for the other fossil fuels (DX 150, A. Ex. 1110); and those industrial consumers for whom capital charges are more significant than fuel prices in relation to total fuel costs are more likely to choose another fuel (DX 102, A. Ex. 990).

For these groups of consumers, whose fuel choice is dictated primarily by considerations other than delivered price, coal is not an effective competitor unless other fuels are unavailable (see DX 150, A. Ex. 1110).

b. The market for coal is therefore effectively confined to electric utilities and other large fuel users, such as cement manufacturers, for whom the delivered price of fuel is the most significant portion of their total cost of doing business (*e.g.*, A. 811–812, GX 43, A. Ex. 63). Except for users of metallurgical coal, most coal consumers burn coal rather than another fuel because of its low price (A. 140, Morris Dep. Ex. 70, A. Ex. 1713).

For this limited class of consumers (or for that portion of a consumer's fuel requirements that are purchased on the basis of delivered price), coal has had minimal competition from other fuels in Illinois and the Eastern Interior Coal Province sales area. Thus, in each of the years 1960 to 1967, coal produced 90 to 94 percent of the BTUs consumed by steam-electric

utility plants in the Province sales area (GX 31, A. Ex. 33). Similarly, in 1967 coal provided 74 percent of the BTUs consumed by cement plants in the Province sales area and 94 percent of that consumed by such plants in Illinois (GX 32, A. Ex. 38–39). Most of the balance of the fuel consumed by these customers is interruptible natural gas (A. 740, GX 32, A. Ex. 39), which is available at a greatly reduced price on a seasonal basis only (see note 15, *supra*).[17] A former United Electric president stated in 1962 (Morris Dep. Ex. 70, A. Ex. 1713):

> We do not have any serious competition in the Midwest from oil for use in industrial and utility plants. We do have severe competition from natural gas when it is dumped at low prices during the summer months when there is no heating load. We feel, however, that with our mining methods and transportation costs, we can continue to hold our position with this competition. It is expected that with the diminishing reserves of gas and the possible higher prices, our competitive relationship with this fuel will improve.

c. Coal's dominance among utility and industrial consumers in the relevant portions of the midwest is not likely to disappear soon. The supply of natural gas is limited and some is being imported in liquified form for use during peak periods (A. 475–476). Gas companies serving the midwest are increasingly stor-

[17] Some oil is used by coal consumers for tasks that coal is not suited for, such as starting up boilers or kilns, and operating diesel units (A. 608, 637, 644, GX 36, A. Ex. 47, Redard Dep. Ex. 1, A. Ex. 1809).

495-300—73——3

ing gas in underground formations or liquified in tanks during low demand periods instead of selling it at the "dump" prices in those months (A. 217–218, 278, 443, 475–476, 481–482, 575, 741, 1209, GX 200, A. Ex. 132). Many coal consumers would not have the facilities to burn gas even if it were available and low-priced (A. 564, 665, DX 59, A. Ex. 509).

Nuclear energy is presently available commercially only for the generation of power, and is not a realistic alternative for non-utility coal consumers (A. 1250). In addition, because a nuclear power plant is different in design and construction from a conventional steam-electric power plant (A. 763, 1252), nuclear fuel is not an available option for use in existing fossil-fuel utility plants (A. 1250). At the time of trial Commonwealth Edison was the only company in the Province sales area that had an operational nuclear plant of commercial size (DX 107, A. Ex. 1004–1005), and nuclear energy accounted for less than one percent of electrical generation in Illinois in 1967 (Kurtz Dep. Ex. 8, A. Ex. 1651–1653).

Although, as the court below found (J.S. App. 34a–35a), newly constructed nuclear plants will account for an increasing share of electric power generation in the midwest, coal burning units will continue to provide a substantial portion. Only larger utilities can economically construct nuclear plants. Witnesses estimated that the minimum economic size of a nuclear power plant is 500 to 800 megawatts (A. 1200, 1239,

1273), and several utility officials stated that their companies' new units are too small for nuclear energy to be a feasible alternative (A. 1200).[18] Even a large utility does not build a 500 megawatt unit each time it expands; when it installs smaller units, it will have to choose among the fossil fuels (A. 1310). There is a continued demand for generating units of less than 500 megawatts in the midwest (Kurtz Dep. Ex. 8, A. Ex. 1654–1655).

Furthermore, large utilities that need additional generating capacity as quickly as possible are likely to choose a conventional plant. It takes as long as eight years to license and construct a nuclear facility and only three to four years to build a conventional unit (GX 232, A. Ex. 153, A. 1118). This need for expedition resulted in the construction of a new coal-fired unit by Commonwealth Edison (A. 1413).

There are other practical obstacles to the installation of nuclear facilities. Construction costs for nuclear plants have increased more rapidly than for coal-fired units (A. 762–763, GX 233, A. Ex. 168, GX 253, A. Ex. 195). Because the industry is still in its infancy, unforeseen difficulties in design, construction, and operation are not uncommon (see A. 676–677). One company revised its estimate of $83 million for a nuclear plant to $112 million because of delays and construction problems (A. 667–668). There are, in

[18] All but one of the 55 nuclear units for which contracts were awarded nationwide from 1967 to 1969 had capacities of at least 500 megawatts, and the average size of those units was nearly 900 megawatts (DX 107, A. Ex. 1005).

addition, problems of thermal pollution, which may be especially difficult to solve in colder climates (see A. 1436).[19]

It is therefore not surprising that announcements of new nuclear units have been declining. The following table shows that, with respect to announced steam-electric plant additions from 1965 through 1969, conventional units account for a growing, not shrinking, proportion of the capacity in the last four years (DX 107, A. Ex. 1007):

Year announced	Fossil		Nuclear		Total
	Megawatts	Percent	Megawatts	Percent	
1965	13,925	73	6,039	27	21,957
1966	20,096	47	22,477	53	42,573
1967	32,320	55	26,460	45	58,780
1968	34,620	62	14,802	26	39,422
1969	37,040	86	6,229	14	43,269
Total	139,984	63	75,978	37	205,962

d. Because of the substantial price advantage coal has over the other fossil fuels in the areas served by Freeman and United Electric, fluctuations in the delivered price of gas and oil are not likely to affect the delivered price of coal. Most coal consumers choose

[19] Two of the defendants' expert economists stated in another context (GX 232, A. Ex. 162):

"The problem of thermal pollution is especially severe for nuclear plants, which are, as yet, considerably less efficient than fossil-fueled plants. A nuclear plant converts about 25 percent less of the heat output into electric energy and, for an equal number of kilowatt hours, discharges about 50 percent more heat into the cooling water than does a fossil-fueled plant. This has already created some difficulties in obtaining construction permits for nuclear plants, and in one instance has necessitated the use of cooling towers."

coal because it is much cheaper and are unlikely to make a sudden switch on the basis of small or temporary reductions in the price of gas or oil—even if that were feasible and even if those fuels were sufficiently available. Thus, in *Kennecott Copper Corp.* v. *Federal Trade Commission*, 467 F. 2d 67, 79 (C.A. 10), petition for certiorari pending, No. 72-637, the court stated that, despite the competition of other fuels, coal prices "are now, and promise to be in the future, subject to the peculiarities of the coal business," and "other fuels appear to have a limited effect."

e. In sum, although coal is undoubtedly subject to some interfuel competition in some areas of the country and competes to a limited degree outside its distinctive market, it has a limited class of customers which is significantly narrower than that for all forms of "energy." Its special advantages are not competitively significant for some fuel customers; for other consumers its advantages give it a clear competitive edge. While other fuels may be attracting the business of some coal customers, thereby diminishing the narrow class, the confines of that class are clear. Thus, as the court held in *Kennecott Copper Corp., supra*, "[t]he coal industry is a distinct submarket which has characteristics which are not shared by the other fuel industries" (467 F. 2d at 79).[20]

[20] The appellees argue (Motion to Affirm, p. 17) that the court below "did not choose energy as the framework for its analysis in order to ignore the merger's competitive implications within the coal industry," but rather "because it assisted in explaining 'what has happened in the *coal* industry and to *its markets*.'"

The situation here is thus like that in *United States* v. *Aluminum Co. of America*, 377 U.S. 271, where this Court held that aluminum conductor is a relevant line of commerce for determining the effects of an acquisition combining a manufacturer of aluminum conductor and a manufacturer of copper and aluminum conductor. The competition between aluminum and copper conductor, upon which the district court had relied in refusing to treat aluminum conductor as a separate line of commerce, was, in the Court's view, "enough to justify grouping aluminum and copper conductors together in a single product market" (377 U.S. at 275). The Court concluded, however, "contrary to the District Court, that that degree of competitiveness does not preclude their division for purposes of § 7 into separate submarkets" (*ibid.*). Aluminum conductor, like coal, "has little consumer acceptance" for many uses but "enjoys decisive advantages" in a narrow application, where its substantially lower price is "the single, most important, practical factor in the business" (*id.* at 275–276). As with coal and other fuels, "aluminum and copper conductor prices do not respond to one another" (*id.* at 276).

The court's opinion, however, reflects no analysis of the structure of the coal submarket or of the impact upon it of the Freeman-United Electric combination. Indeed, the appellees have agreed that what they call the "subsidiary technicalities of market definition were not determinative of the decision below" (Motion to Affirm, p. 15). This Court, however, has repeatedly emphasized the importance of a proper market definition in determining the probable effects of a combination. *E.g.*, *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 322, n. 38, 343; *United States* v. *Continental Can Co.*, 378 U.S. 441, 458, 459–460, n. 10.

B. THE DISTRICT COURT'S CONCLUSION THAT ENERGY IS THE EXCLUSIVE RELEVANT LINE OF COMMERCE RESTED UPON A MISUNDERSTANDING OF UNITED STATES V. CONTINENTAL CAN CO., 378 U.S. 441.

The district court, after an extensive discussion of interfuel competition (J.S. App. 27a–53a), concluded that *United States* v. *Continental Can Co.*, 378 U.S. 441, "compel[s] this Court to conclude that since coal competes with gas, oil, uranium and other forms of energy, the relevant line of commerce must encompass interfuel competition" (J.S. App. 55a).[21] This conclusion rests upon a misunderstanding of *Continental Can*.

Continental Can involved the merger of a large producer of metal containers and a large producer of glass containers. The district court, although recognizing that there was substantial "interindustry competition" between the two products, held that the only appropriate lines of commerce were the can industry and the glass container industry separately and rejected various broader markets covering both products (378 U.S. at 447–448). This Court reversed,

[21] Despite the district court's express holding that "the energy market is *the* appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination" (J.S. App. 53a, emphasis added), it seemingly recognized, in its discussion of the relevant geographic markets, that coal is a separate product. Thus, the geographic markets, were defined on the basis of "the distributive patterns of * * * coal" (*id.* at 56a); the discussion focused on "those facilities for whose business coal mines are able to compete and those mines to which coal consumers can practicably turn for supplies" (*id.* at 57a). The sections of the country defined by the court were called "coal market[s]" (*id.* at 58a).

holding that "the interindustry competition between glass and metal containers is sufficient to warrant treating as a relevant product market the combined glass and metal container industries and all end uses for which they compete" (p. 457, emphasis added). Although "[g]lass and metal containers were recognized to be two separate lines of commerce," the Court ruled (pp. 456–457) that "given the area of effective competition between these lines, there is necessarily implied one or more other lines of commerce embracing both industries."

Continental Can was thus an application of the settled principle that there may be many relevant lines of commerce. It reflected the economic reality that where there is substantial competition between related products in different industries, the line of commerce to be used in examining a merger between companies in those industries must be drawn sufficiently broadly to "conform to competitive reality" (p. 457) and should not be limited "to competition between identical products" (p. 452). All that *Continental Can* suggests with respect to the energy market is that, in evaluating a merger between companies in different segments of that market—for example, the acquisition of a coal company by a natural gas producer—it would be appropriate to define a line of commerce to include both products.

There is nothing in *Continental Can,* however, which even suggests that, in evaluating a merger of two companies in the same industry, the market must be drawn to include other industries which compete with that industry. *Continental Can* dealt with the

question of how broadly a line of commerce may be drawn, not how narrowly, and the Court explicitly stated (p. 457) that the interindustry line of commerce it selected was "a" relevant product market. *Continental Can* cannot be read, as the district court in effect interpreted it, as indicating that, in evaluating a merger of two can companies or two glass companies, neither product alone would be a relevant line of commerce. To the contrary, the Court accepted the district court's conclusion that glass and metal containers were "two separate lines of commerce" (p. 456; see, also, p. 447), and ended its discussion of the relevant line of commerce with the statement from *Brown Shoe,* quoted above, that "within this broad market, well-defined submarkets may exist which, in themselves, constitute product markets for antitrust purposes" (p. 458, quoting from 370 U.S. at 325).

Continental Can, therefore, supports rather than refutes the government's contention that coal is a relevant line of commerce for testing the competitive impact of this merger of coal companies. See, also, *United States* v. *Aluminum Co. of America, supra.*

II

ILLINOIS AND THE EASTERN INTERIOR COAL PROVINCE SALES AREA ARE APPROPRIATE SECTIONS OF THE COUNTRY FOR DETERMINING THE COMPETITIVE EFFECTS OF THE ACQUISITION

The district court further erred in rejecting the two geographic markets the government proposed—the Eastern Interior Coal Province sales area and the State of Illinois, which is part of that sales area—and

instead adopting as the sole relevant sections of the country the ten markets the defendants proposed. The court's error in defining geographic markets was the reverse of its error in defining the product market. In choosing energy as the exclusive line of commerce, the court ignored relevant submarkets; in adopting the ten geographic markets, the court ignored relevant broader markets which constituted appropriate sections of the country.

A. THE GEOGRAPHIC MARKETS PROPOSED BY THE GOVERNMENT CORRESPOND TO THE REALITIES OF THE COAL INDUSTRY AND ARE ECONOMICALLY SIGNIFICANT

This Court in *Brown Shoe* identified the criteria for selecting appropriate sections of the country for Section 7 purposes (370 U.S. at 336–337): "[t]he geographic market selected must * * * both 'correspond to the commercial realities' of the industry and be economically significant." The Court emphasized that the combination is unlawful if "anticompetitive effects * * * are probable in 'any' significant market" (*id.* at 337). As the Court reiterated in *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 549, the government is not required to delineate sections of the country "by metes and bounds" but need only show that the combination "may have a substantial anticompetitive effect somewhere in the United States—'in *any* section' of the United States."

The government here showed that the Freeman-United Electric combination may have a substantial anticompetitive effect in two sections of the country—the Eastern Interior Coal Province sales area and the

State of Illinois. Each corresponds to the competitive realities of the coal industry and is economically significant. Each is an appropriate geographic market.

1. The Eastern Interior Coal Province sales area is a relevant section of the country.

Transportation costs and the uneven distribution of coal deposits are the fundamental commercial realities affecting market structure in the coal industry (see J.S. App. 57a, Kurtz Dep. Ex. 10, A. Ex. 1657). These factors tend to insulate producers in one coal province from competition by producers in another coal province, and thereby to establish identifiable geographic markets. As the court below recognized (J.S. App. 57a), since transportation costs may be 30 to 40 percent of coal's delivered price, a consumer's geographical proximity to a mine and the resulting costs of transporting coal from the mine, are critical factors affecting the choice of a coal supplier. Because coal is found primarily in four producing regions (see p. 5, *supra*), a consumer's choice of a supplier is likely to be made from among producers within the nearest or most accessible region. The competitive sales areas for producers within a region thus conform generally to the geographic range beyond which transportation costs result in a delivered price that is higher than that for coal originating in another producing region.

The Eastern Interior Coal Province, within which all of Freeman's and United Electric's mines are located, is one of the country's four coal producing regions; it consists of the central and southern two-thirds of Illinois, southwestern Indiana, and western

Kentucky (Kurtz Dep. Ex. 10, A. Ex. 1657). The region is geologically united, and underlain by a coal-bearing sequence of rock known as the Pennsylvania System (A. 292–293, 679–681, 685). It is estimated that the region contains over 240 billion tons of bituminous coal resources, some 36 percent of the Nation's total resources (Kurtz Dep. Ex. 10, A. Ex. 1661).[22]

Because of the Province's geographic separation from the other producing regions (see Kurtz Dep. Ex. 10, A. Ex. 1657), its coal producers generally enjoy a competitive advantage over producers in other provinces with respect to sales to consumers in an identifiable sales area (A. 33–36). This sales area, within which most of the coal produced in the region and nearly all the coal produced by Freeman and United Electric is sold, comprises Illinois, Indiana, west Kentucky, west Tennessee, east Iowa, southeast Minnesota, south Wisconsin, and the extreme eastern portion of Missouri.[23]

---

[22] The coal industry and the public generally recognize the Eastern Interior Coal Province as a distinct geographic producing area (see A. 36–40, 74, 277, 330–331, 334–335, 694). The Mid-West Coal Producers Institute, Inc., a trade association for producers in the region, publishes monthly and annual production figures for mines within the Province (A. 327–329, 333–334).

[23] Bureau of Mines data reflecting the origin of coal shipments to each state show that an overwhelming proportion of the coal sold in Illinois and Indiana is produced in the Eastern Interior Province and that a substantial portion (40 to 90 percent) of the coal sold in the other states mentioned above originates in the Province (Gallagher Dep. Ex. 3, A. Ex. 1428–1429).

In 1967 about 82 percent of the coal produced in the Eastern Interior Coal Province was sold in the province sales area (GX 52, A. Ex. 67), and nearly 100 percent of the coal consumed by steam-electric utilities located within the sales area was produced in Province mines (GX 61, A. Ex. 79). In the same year Freeman sold 93.3 percent of its coal and United Electric sold 97.6 percent of its coal in the primary sales area (GX 52, A. Ex. 67).

The appellees' annual reports and advertisements acknowledge the ability of Freeman and United Electric to serve consumers throughout the midwest (see, *e.g.*, GX 5, p. 22, Kolbe Dep. Ex. 51, pp. 18–19, Nugent Dep. Exs. 14–16, Nugent Dep. Ex. 17, A. Ex. 1769, Nugent Dep. Ex. 19, A. Ex. 1771, and Nugent Dep. Ex. 20, A. Ex. 1773). Both United Electric and Freeman have at one time or another shipped coal to almost every State within the Province sales area (A. 218–230, 234–242, 250–255, GX 54–60, A. Ex. 68–78).

2. Illinois is a relevant section of the country.

Illinois has more coal resources than any other State (Kurtz Dep. Ex. 10, A. Ex. 1661, A. 681), and is the fourth largest producing State in terms of annual tons (Kurtz Dep. Ex. 10, A. Ex. 1660). The State was designated Mining District 10 under the Bitumi-

---

The location of other coal deposits in or near portions of some of the states suggests that Eastern Interior Province sales are not evenly distributed throughout the state but are concentrated in that portion which is closest to the Eastern Interior Province. Industry witnesses confirmed that Province sales were concentrated in the sections of the states indicated above (A. 275–277, 336–338, 601).

nous Coal Act of 1937, 50 Stat. 72, 78, 15 U.S.C. (1940 ed.) 833. Separate production and distribution data are reported for the State by the United States Bureau of Mines (Gallaher Dep. Ex. 3, A. Ex. 1428–1429, Kurtz Dep. Exs. 9–10, A. Ex. 1650–1661). All the Freeman and United Electric mines are in Illinois.

In 1967, 82 percent of the coal consumed in Illinois was produced within the State,[24] and 90 percent of the coal consumed by Illinois steam-electric utilities was produced in the State[25] (Gallagher Dep. Ex. 3, A. Ex. 1428). In the same year, about 58 percent of the coal produced in Illinois was sold in the State (Gallagher Dep. Ex. 3, A. Ex. 1424–1447). Freeman sold about 42 percent of its coal, and United Electric sold about 62 percent of its coal, to Illinois consumers.[26]

Thus, within the broader Province sales area Illinois is an economically significant submarket in which coal users buy most of their fuel from Illinois producers and in which producers, including Freeman and United Electric, sell more coal then they sell in any other state. The impact of the combination within the State is likely to be even more "direct and immediate" than in the broader Province sales area. See *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 357. Because Illinois coal sales are dominated by Illinois producers, and because all the Freeman and United

[24] The figures for 1965 and 1966 were 77 percent and 81 percent, respectively (Gallagher Dep. Exs. 1, 2).

[25] The figures for 1965 and 1966 were 87 percent and 90 percent, respectively (*ibid.*).

[26] These facts were conceded by appellees in response to the government's proposed finding VI(A)(10).

Electric mines are in Illinois, structural data for the Province sales area as a whole will predictably understate the combination's effects within the Illinois submarket.

Although political boundaries do not always precisely parallel economic boundaries, both the government's and the appellees' expert witnesses testified that they are sometimes the best available approximation of a market (A. 1566, 1697). Cf. *United States* v. *Philadelphia National Bank*, 374 U.S. 321, where the relevant section of the country was a four-county area in which the consolidating banks had their offices; this Court, acknowledging the "artificiality" of the dividing line, stated that "such fuzziness would seem inherent in any attempt to delineate the relevant geographical market" (374 U.S. at 360, n. 37). States, of course, have frequently been held to be relevant geographic markets or submarkets. In *United States* v. *Pabst Brewing Co., supra*, for example, this Court determined that the relevant markets for assessing a merger of brewers were the Nation, the three-state area of Wisconsin-Illinois-Michigan, and the State of Wisconsin alone. There, as here, because the combination would have a significant effect within the state boundaries as well as in the broader markets, it was appropriate to consider those effects. See, also, *United States* v. *El Paso Natural Gas Corp.*, 376 U.S. 651, 657, where this Court stated that there could "be no doubt that California is a 'section of the country' as that phrase is used in § 7."

3. The district court erred in rejecting these areas as relevant sections of the country.

The reasons the court gave for rejecting the Province sales area and Illinois as "sections of the country" are unsound. The court stated that these two regions reflect "past and present production statistics" but "do not relate to actual coal consumption patterns" (J.S. App. 56a). We have already shown, however, that transportation costs and the availability of coal from other areas limit the market for Eastern Interior Province coal, that a very large portion of Province coal is consumed in its sales area, and that nearly all the coal sold in the sales area is produced in the Province (pp. 37–39, *supra*). Similarly, we have shown that a very large proportion of the coal used by Illinois consumers is produced in Illinois, and that most of the coal produced by Illinois mines is sold in the State (p. 40, *supra*).

The appellees argue (Motion to Affirm, pp. 19–21) that individual mines are so limited by transportation costs that they can sell only in a small portion of the Province sales area or the State. The record shows, however, that the competitive range of a mine is much broader than the appellees contend. A producer ordinarily encounters more competition as the distance which coal is shipped increases, because transportation costs ordinarily increase with distance (A. 28–29). But a producer can be a strong competitive factor as far as 500 miles from his mine.

In 1967, for example, Freeman's Orient mines in southern Illinois shipped 260,000 tons of coal 500 miles

to customers in Michigan (GX 55, A. Ex. 74, GX 56, A. Ex. 75), and 1.3 million tons to customers 300 to 500 miles from the mines (GX 55, A. Ex. 74, GX 56, A. Ex. 75, GX 57, A. Ex. 76). United Electric's Fidelity mine, located within 40 miles of the three Orient mines (Weir Dep. Ex. 1, A. Ex. 1845), shipped more than one million tons of coal to customers 300 to 500 miles away (GX 60, A. Ex. 79). These shipments represented more than half of the Fidelity mine's total production. Within the Eastern Interior Coal Province, most mines are situated within 500 miles of most locations in the Province sales area, and Freeman and United Electric both have mines that can supply any point in the sales region."

That no one producer sells coal, and no one consumer buys coal, "throughout" the sales area (J.S. App. 56a) does not imply that the area is too large to be a relevant section of the country. In *Tampa Electric Co.* v. *Nashville Coal Co.*, 365 U.S. 320, this Court held that a requirements contract between a Florida utility and a Tennessee coal producer did not violate Section 3 of the Clayton Act because the estimated total consumption of the utility would amount to only about one percent of the coal produced by mines within the competitive producing area. The Court determined that producers throughout the Appalachian region and portions of the Eastern Interior Coal Province could supply the Florida utility, and that all of these producing districts should therefore be considered part of the relevant market."

[27] Although Freeman did not sell any coal in Minnesota or Tennessee in 1967, a former Freeman president testified that Freeman could sell coal competitively in both states (A. 26–27).

[28] Because of Florida's location in relation to the Eastern and

Similarly, here, the important consideration is competitive ability. Since most mines within the Province can competitively supply most consumers in the sales area, it is an appropriate section of the country for Section 7 purposes, notwithstanding that no single mine in fact sells in every portion of the sales area at a given time.

B. THE GEOGRAPHIC MARKETS THE DISTRICT COURT ADOPTED ARE IMPROPER, BUT IN ANY EVENT THEY DO NOT NEGATE THE BROADER MARKETS OF ILLINOIS AND THE EASTERN INTERIOR COAL PROVINCE SALES AREA

The district court apparently adopted, as the exclusive sections of the country for purposes of Section 7, a patchwork of ten "geographic" markets proposed by the appellees.[28] The court's discussion (J.S. App. 56a–60a) indicates that it assumed it was required to choose between the smaller markets proposed by appellees or the broader ones proposed by the government. That assumption is erroneous.

As with product markets,[29] there may be more than one relevant section of the country, and narrow geographic markets do not negate the existence of one or more broader markets in which the combination

---

Eastern Interior Coal Provinces, producers in both regions are able to compete for the business of that State's coal consumers (see Gallagher Dep. Ex. 3, A. Ex. 1438).

[28] The court did not separately identify each of these ten markets, but its discussion indicates that it accepted the appellees' market delineations (J.S. App. 56a–59a).

[29] The standards for identifying relevant sections of the country "are essentially similar to those used to determine the relevant product market" (*Brown Shoe*, 370 U.S. at 336).

will have an effect. Since the statute speaks of "any" section of the country, it is improper to ignore the larger market merely because the smaller one seems also appropriate. In *Pabst Brewing Co., supra*, the Court evaluated the impact of the merger in the Nation as a whole and in a specific three-state area, even though the State of Wisconsin was by itself a relevant section of the country.

The markets that the district court adopted, however, are not appropriate sections of the country for determining the competitive effects of the Freeman-United Electric combination even if they are considered to be additional rather than exclusive markets. The court's markets are purportedly based on the areas served by producers in the four freight rate districts in which Freeman's and United Electric's mines were located at the time of trial.[21] The appellees argued that, since the normal rail rates for coal are the same for all mines in a particular freight rate district, and since transportation costs are the principal competitive factor in the marketing of coal, mines in one district could not effectively compete with mines in another district for the same customers.

The conclusion, however, does not follow from the premises. Although transportation costs are a primary competitive consideration, ordinary *rail* rates are not

[21] Illinois is divided into eight freight rate districts: Mineral-Atkinson, Northern Illinois, Fulton-Peoria, Springfield, Danville, Murdock, Belleville, and Southern Illinois (see Weir Dep. Ex. 1, A. Ex. 1845). The United Electric mines are located in the Fulton-Peoria and Belleville districts; the Freeman mines are located in the Springfield and Southern Illinois districts.

the single controlling element in transportation costs. The record shows that about half of the coal sold in the five states that received most of the Illinois coal in 1967 was transported by all-rail shipments (Gallagher Dep. Ex. 3, A. Ex. 1424–1427). To the extent that other modes of transportation are employed, the railroad rates do not necessarily determine the delivered price of the coal. That is particularly true for United Electric, which transports most of its coal by barge (A. 271–274).

Moreover, the most competitively significant rail shipments are not governed by the ordinary rail rates for each freight rate district. Many of the largest shipments are transported by "unit trains" carrying only coal between a particular mine and a customer's facility pursuant to a specially negotiated rate. Freeman, for example, has shipped coal by unit train from a mine in the Southern Illinois district to a customer in the Belleville district sales area at a cost which is lower than any Belleville district rate to that location (A. 30–31).

Moreover, the freight rate district sales areas adopted by the district court do not include major portions of the sales of producers located in a single freight rate district. All the facilities of Commonwealth Edison Company are treated as a separate single market although they range throughout a substantial geographic area and are served by producers in different freight rate districts. Customers located in the Chicago Air Quality Control Region also constitute a separate market. Moreover, all the customers within the sales

area of a particular freight rate district are not included in a single market. Such customers are divided into two categories, utility and non-utility firms, and each category is treated as a separate section of the country.[32] The result, as shown by the map facing page 48, is a crazy-quilt of artificial, noncontiguous sales areas, which do not reflect the way coal is marketed.

The map shows only six of the appellees' ten markets: the four freight rate district utility sales areas, the Chicago Air Quality Control Region, and the Commonwealth Edison Company.[33] One of these markets, represented in red, consists of three noncontiguous sections embracing parts of seven states. A second market, shown in blue, consists of two sections which are not contiguous to each other but are each contiguous to one of the three sections of the first market. A third market, shown in green, is a single section which is contiguous to one of the sections of the second

[32] Coal sold as dust also was excluded in defining sales areas. There is no basis for treating coal dust and coal screenings as separate products. See pp. 61–62, *infra*. The exclusion of dust necessarily distorted the sales area analysis. Producers in a single freight rate district (Southern Illinois) sold approximately one million tons of dust (constituting approximately 10 percent of their utility sales, DX 55, A. Ex. 475) to utilities in the sales area of another freight rate district.

[33] The map is based on the appellees' descriptions of the sales areas (A. 969, 972–977). Since those descriptions are somewhat imprecise, the map does not purport to be exact. It is an approximation of the six geographic markets. The four non-utility sales areas, which are not shown, are reasonably close to the utility areas, except that the Fulton-Peoria area (yellow) is larger and the Belleville area (blue) is limited to the lower section.

495-300—73——5

market. The Commonwealth Edison facilities, represented by black dots, are a separate market which is partially within three other markets. In sum, appellees' sales areas are "an obvious gerrymandering * * * to meet the exigencies of this case." *United States* v. *Bethlehem Steel Corp.*, 168 F. Supp. 576, 599 (S.D. N.Y.).

The artificiality of the appellees' markets is revealed by the fact that the eight sales areas for the four freight rate districts accounted for less than half of the total coal produced in those districts.[44] Nor did the eight markets accurately reflect the distribution of United Electric and Freeman coal. Some 25 percent of the coal produced in United Electric's Belleville district mine, for example, was sold to customers located in the Southern Illinois district sales areas (GX 60, A. Ex. 78), while nearly 20 percent of Freeman's Southern Illinois coal was sold in the Belleville sales areas (GX 55–57, A. Ex. 74–76). The two companies, though their mines were in different districts, sold about half of their production to common customers (GX 88–91, A. Ex. 107–117).

Moreover, because these markets were delineated on the basis of only one year's sales data, they necessarily reflected only the actual sales for that period and not the competitive ability of producers within the various districts who might, in another year, sell coal in a

[44] Only 46 percent of the coal produced in the Fulton-Peoria district was sold in appellees' utility and non-utility sales areas for that district; the figures for Springfield, Belleville, and Southern Illinois were 19, 47, and 70 percent, respectively (DX 55, A. Ex. 465, 468, 473, 478).

different geographic range (see A. 1670)." Similarly, the appellees' markets mask the competiton among mines in different freight rate districts for the business of new plants. With the development of high-voltage transmission lines, it is not uncommon for a utility to construct a plant near a mine that is several hundred miles away from the area the plant will serve (GX 239, A. Ex. 179, Kurtz Dep. Ex. 9, A. Ex. 1656). The appellees' expert conceded that a coal consumer may consider alternative suppliers located in various freight rate districts before settling on the site for a new facility (A. 1671).

Despite these deficiencies, the district court accepted the appellees' markets as the exclusive sections of the country for purposes of Section 7.[25] In our view "the

[25] Some of the markets were defined on the basis of only a few customers or sales. For example, the Springfield non-utility market consisted of two plants in Decatur, the Springfield utility sales area was two plants near Springfield, and the Fulton-Peoria utility area consisted of three customers with six plants on the Illinois River (DX 55, A. Ex. 462, 466–467). Subsequent developments demonstrated the danger of basing markets on so small a sampling of transactions. All three Fulton-Peoria area utilities have purchased from or negotiated with Springfield producers (A. 439–440, 1211, DX 55, A. Ex. 462, n. 1); a Fulton-Peoria mine has contracted to ship a million tons a year to a utility in Wisconsin (A. 609–610, 1640). That contract is for about half the tonnage sold to the three Fulton-Peoria area utilities in 1967 (DX 55, A. Ex. 462).

[26] Although the court stated that it would have reached the same conclusions even if it had accepted the government's geographic markets (J.S. App. 59a–60a), its discussion of competitive effects rested squarely on its view that "[t]he Freight Rate Districts in which the mines and reserves of United Electric are located serve separate and distinct markets from those in which the mines of Freeman are located" (J.S. App. 62a). The

pie [does not] slice so thinly." *Tampa Electric Co.* v. *Nashville Coal Co.*, 365 U.S. 320, 331. The district court ignored this Court's direction that "[t]he proper question to be asked * * * is not where the parties to the merger do business or even where they compete, but where, within the area of competitive overlap, the effect of the merger on competition will be direct and immediate." *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 357. Instead of selecting sections of the country in which the competitive impact of the Freeman-United Electric combination would most likely be felt, the court below chose one of the "indefensible extremes" against which this Court cautioned in *Philadelphia National Bank*—it drew the market "so narrowly as to place appellees in different markets" (374 U.S. at 361).

III

THE EFFECT OF THE ACQUISITION MAY BE SUBSTANTIALLY TO LESSEN COMPETITION IN THE RELEVANT MARKETS

A. A HORIZONTAL MERGER IS ILLEGAL UNDER SECTION 7 IF IT SIGNIFICANTLY INCREASES CONCENTRATION IN A CONCENTRATED MARKET

Amended Section 7 of the Clayton Act prohibits a merger whose effect "may be substantially to lessen competition." Congress was concerned in 1950 with the rising trend toward concentration in the American economy, and it amended Section 7 in order to prevent mergers which produced anticompetitive changes in market structure, *i.e.*, those which threatened to weaken the normal play of competitive market forces. opinion contains no discussion of the effect of the combination on competition within the sections of the country proposed by the government (J.S. App. 60a–64a).

Brown Shoe, supra, 370 U.S. at 315–316, 320–322. Whether a horizontal merger has the proscribed effect under Section 7—and that Section deals with probabilities, not certainties—thus depends upon its effect on the structure of the relevant markets.

In *Brown Shoe* this Court stated that statistics "reflecting the shares of the market controlled by the industry leaders and the parties to the merger are, of course, the primary index of market power" (370 U.S. at 322, n. 38).[37] Where the merger produces a firm that controls an "undue" percentage share of the market and significantly increases concentration in the market, those facts alone establish *prima facie* that the effect of the merger may be substantially to lessen competition. *United States* v. *Philadelphia National Bank,* 374 U.S. 321, 363; *United States* v. *Continental Can Co.,* 378 U.S. 441, 458. The Court stated in *Philadelphia National Bank,* 374 U.S. at 363:

> This intense congressional concern with the trend toward concentration warrants dispensing, in certain cases, with elaborate proof of market structure, market behavior, or probable anticompetitive effects. Specifically, we think that a merger which produces a firm controlling an undue percentage share of the relevant market, and results in a significant increase in the concentration of firms in that market is so in-

[37] The Court also stated (370 U.S. at 343):

"The market share which companies may control by merging is one of the most important factors to be considered when determining the probable effects of the combination on effective competition in the relevant market."

See, also, *United States* v. *Continental Can Co., supra,* 378 U.S. at 458.

herently likely to lessen competition substantially that it must be enjoined in the absence of evidence clearly showing that the merger is not likely to have such anticompetitive effects.

The Court noted also that in a market where "concentration is already great, the importance of preventing even slight increases in concentration and so preserving the possibility of eventual deconcentration is correspondingly great" (374 U.S. at 365, n. 42).

The Court in *Philadelphia National Bank* did not specify a minimum combined share which would establish *prima facie* illegality. It concluded, however, that the merging banks' combined share of more than 30 percent of the relevant market was sufficient to invoke the principle. In *United States* v. *Von's Grocery Co.*, 384 U.S. 270, and *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, the Court applied the principle to invalidate combinations involving considerably smaller combined shares where the markets had experienced a rapid increase in concentration. "[A] trend towards concentration in an industry, whatever its causes, is a highly relevant factor in deciding how substantial the anticompetitive effect of a merger may be" (*Pabst*, 384 U.S. at 552–553)."

In *Von's*, there had been a rapid decline in the number of single-store retail groceries in the market, an increase in the number of chains, and a history of acquisitions and mergers; the merger in question com-

"In *Von's* the Court stated that "where concentration is gaining momentum in a market, we must be alert to carry out Congress' intent to protect competition against ever-increasing concentration through mergers" (384 U.S. at 277).

bined the third and sixth largest chains with a combined share of 7.5 percent of the market. "These facts alone," the Court said, "are enough to cause us to conclude contrary to the District Court that the Von's-Shopping Bag merger did violate § 7" (384 U.S. at 274).

In *Pabst* the Court held that *prima facie* illegality had been established in three sections of the country. In the Nation as a whole, the acquisition combined the 10th and 18th largest brewers to form the fifth largest with about 4.5 percent of the market. In the Wisconsin-Illinois-Michigan area, the combination of the sixth and seventh largest brewers controlled about 11 percent of the market. In Wisconsin, the first and fourth largest combined to form the largest with 24 percent of the market (384 U.S. at 550–551). In each of these markets there had been a significant increase in concentration.[29]

In *United States* v. *Aluminum Co. of America*, 377 U.S. 271, the Court held unlawful a merger of the first and ninth largest producers of aluminum conductor, where the resulting combination controlled 29.1 percent of the aluminum conductor market and 16.3 percent of the narrower market of insulated alu-

[29] In the Nation, between 1957 and 1961, the number of sellers decreased from 206 to 162, and the top ten firms increased their share from 45 percent to 53 percent. In the three-state area, the number of breweries dropped from 104 to 86, and the share of the top eight companies grew from 59 percent to 68 percent. In Wisconsin, the number of firms went from 77 to 54, and the four leading companies boosted their share from 48 percent to 59 percent. (384 U.S. at 550–551.)

minum conductor.[40] In *United States* v. *Continental Can Co., supra*, the unlawful merger had resulted in a combined share of 25 percent of the metal and glass container market.[41]

B. UNDER THESE CRITERIA THE FREEMAN-UNITED ELECTRIC COMBINATION IS UNLAWFUL

1. The market is concentrated and the trend is toward further concentration.

As shown in the table on page 6, *infra*, in 1957 the top two coal producers in the Eastern Interior Coal Province had 29.6 percent of the production, the top four had 43.0 percent, and the top ten had 65.5 percent. Concentration in Illinois was even greater: the top two had 37.8 percent, the top four had 54.5 percent, and the top ten had 84.0 percent of the production. The pre-merger concentration levels in the relevant markets in this case, in *Von's*, and in *Pabst* are shown in the following table:

	Province	Illinois	Von's	Pabst, Wisconsin	Pabst, 3-State	Pabst, National
Top 2	29.6	37.8	----	----	----	----
Top 4	43.0	54.5	38.4	47.7	----	----
Top 8	----	----	60.9	----	58.9	----
Top 10	65.5	84.0	----	----	----	45.1
Top 12	----	----	65.6	----	----	----

[40] Both markets were concentrated. In the aluminum conductor market, the top two firms controlled 50 percent, the top five 76 percent, and the top nine 95.7 percent. In the insulated aluminum conductor market, the top five had 65.4 percent and the top nine had 88.2 percent. (377 U.S. at 278.)

[41] The top two firms in that market had 48.7 percent of the business, the top four had 62.7 percent, and the top six had 70.1 percent (378 U.S. at 461, n. 11).

Both geographic markets here thus were concentrated prior to the time Material Service assumed control of United Electric in 1959, and concentration rapidly increased between 1957 and 1967. In the Province sales area the share of the top two producers increased about 65 percent (29.6 percent to 48.6 percent), the top four's share rose about 46 percent (43.0 to 62.9), and the top ten's share increased about 40 percent (65.5 to 91.4). In Illinois the comparable figures were 43 percent (37.8 to 52.9), 38 percent (54.5 to 75.2), and 17 percent (84.0 to 98.0). These increases were, for example, significantly greater than those in *Von's,* where, over a ten-year period prior to the merger, the top four's share of the market had slightly decreased, the top eight's share had risen about 21 percent, and the top twelve's had increased about 26 percent.

In addition, between 1957 and 1967 the number of coal producers in Illinois decreased approximately 73 percent, from 144 to 39 (GX 73, A. Ex. 92). In *Von's,* by comparison, between 1950 and 1961 the number of single stores dropped only about 30 percent, from 5,365 to 3,818.

The district court apparently discounted the decline in the number of producers on the ground that the reduction "has occurred not because small producers have been acquired by others, but as the inevitable result of the change in the nature of demand for coal" (J.S. App. 60a). This Court has held, however, that the government is not required to show that a trend toward concentration is due to mergers. *Pabst, supra,*

384 U.S. at 552–553. "[A] trend toward concentration in an industry, whatever its causes, is a highly relevant factor in deciding how substantial the anticompetitive effect of a merger may be" (*ibid.*). Moreover, the record contains a four-page exhibit showing that at least 22 Eastern Interior Coal Province producers were acquired by other companies between 1955 and 1968; these acquisitions involved the transfer of control over 40 mines (GX 87, A. Ex. 101–106).

Appellees argue (Motion to Affirm, pp. 12–13, n. 11) that there is no pronounced trend toward concentration because, apart from Peabody Coal Company, the market shares of the other leading producers remained relatively stable over the ten-year period. But the effects of an increasingly concentrated market structure are not mitigated merely because the increases are caused chiefly by a single company. Nor is a merger's anticompetitive impact minimized because the combining companies' shares of the increasingly concentrated market have remained constant. See *Federal Trade Commission* v. *Procter & Gamble Co.*, 386 U.S. 568, 576–577.

The significant consideration is that increases in market concentration, whatever their cause, diminish the vigor of competition; it was this rising trend in concentration that Congress intended to halt in the 1950 amendments to Section 7 (pp. 50–51, *supra*). Appellees do not dispute that the trend in the Province and Illinois, without excluding Peabody or any other producer, is toward concentration.

2. The merger is prima facie unlawful because it produces a firm with an undue percentage share of these concentrated markets and significantly increases concentration there.

The acquisition of United Electric brought together two of the leading companies in each of these concentrated markets, and the market shares of the resulting Freeman-United Electric combination show that the acquisition "is of such a size as to be inherently suspect" (*Continental Can, supra,* 378 U.S. at 458). This is true whether the acquisition is viewed as of 1959, when Material Service obtained effective control over United Electric (J.S. App. 8a), or as of 1967, when United Electric became a wholly-owned subsidiary of General Dynamics (J.S. App. 9a).

The record contains detailed production data for mines in the Eastern Interior Coal Province and Illinois. Because of the correlation between production in Province mines and sales in the Province sales area, and between production in Illinois mines and sales to Illinois customers (see pp. 39–40, *supra*), the structural data based on production is a fair measure of the competitive impact of the acquisition within the two markets. Coal consumers in those areas will be directly affected by the alteration of the competitive structure of coal producers.

The following table shows, for 1959 and 1967, the ranking and share of coal production for Freeman,

United Electric, and the two combined, in both the Eastern Interior Coal Province and Illinois:

	Province		Illinois	
	Rank	Share (percent)	Rank	Share (percent)
1959 (GX 44, A. Ex. 60; GX 77, R. Ex. 90):—				
Freeman	2	7.6	2	15.1
United Electric	6	4.8	5	8.1
Combined	2	12.4	1	23.2
1967 (GX 73, A. Ex. 94; GX 95, A. Ex. 98):—				
Freeman	3	6.5	2	12.9
United Electric	9	4.4	6	8.9
Combined	2	10.9	2	21.8

The combined companies' shares of these markets are thus within the range of shares that this Court has held *prima facie* unlawful. The Illinois figures of 23.2 and 21.8 percent approach the 23.95 percent share in the *Pabst* Wisconsin market, the 25 percent share in *Continental Can*, and the 29.1 percent share in *Alcoa*. The Province figures of 12.4 and 10.9 percent approximate the shares held unlawful in the *Von's* (7.5), *Pabst* National (4.49), and *Pabst* three-state (11.32) markets.

The acquiring company, both in 1959 and 1967, substantially increased its market share. When it assumed control of United Electric in 1959, Material Service enlarged its percentage share of coal production in the Province from 7.6 to 12.4, an increase of about 63 percent; in Illinois its share grew from 15.1 to 23.2 percent, a jump of about 53 percent. Viewing the acquisition as a 1967 transaction, General Dynamics' share in the Province increased from 6.5 to 10.9 percent, a growth of 68 percent; in Illinois its share increased from 12.9 to 21.8 percent, a growth of

70 percent. These increases greatly exceed that in *Continental Can, supra,* where an increase of only 14 percent was held unlawful (378 U.S. at 461).

The acquisition also resulted in substantial increases in market concentration in each of the relevant areas. Since in each market for both 1959 and 1967 the Freeman-United Electric combination ranks first or second, it becomes relevant to examine the market shares of the top producers in those markets for those years but for the merger. In the following table, we compare such market shares to the shares of the top two producers given consummation of the merger, and show the resulting percentage increase in concentration.

	1959 (GX 64, A. Ex. 28, GX 77, A. Ex. 69)			1967 (GX 72, A. Ex. 91, GX 86, A. Ex. 94)		
	Share of top 2 but for merger	Share of top 2 given merger	Percent increase	Share of top 2 but for merger	Share of top 2 given merger	Percent increase
Province	33.1	37.9	14.5	45.0	48.6	8.0
Illinois	36.2	44.3	22.4	44.0	52.9	20.2

Thus, the immediate effect of the combination in either year, was to make an already concentrated market even more concentrated.

These structural data establish that the acquisition, whether viewed as of 1959 or 1967, "produce[d] a firm controlling an undue percentage share of the relevant market, and result[ed] in a significant increase in the concentration of firms in that market" (*Philadelphia National Bank, supra,* 374 U.S. at 363). It is therefore "inherently likely to lessen competition substantially" and "must be enjoined in the absence of evidence clearly showing that the merger is not likely

to have such anticompetitive effects" (*ibid.*). There is, as we show below (pp. 63–75), no such evidence in this case.

c. THE ACQUISITION IS ALSO ILLEGAL BECAUSE IT ELIMINATES SUBSTANTIAL COMPETITION BETWEEN FREEMAN AND UNITED ELECTRIC

1. As the table on page 11, *supra*, illustrates, Freeman and United Electric sell about half of their coal to common customers, and most of those sales are to identical customer facilities. Indeed, even in appellees' Commonwealth Edison market the two companies have been substantial competitors. In the years 1965 through 1967, United Electric shipped about 31 percent of its coal and Freeman shipped about 21 percent of its coal to identical facilities of the Commonwealth Edison Company (GX 70–72, A. Ex. 89–91, GX 88–90, A. Ex. 107–116).[42]

Salesmen of the two companies have actively solicited the same customers (A. 48, 121), and the companies have been asked to make bids to supply the same customer (see GX 104, A. Ex. 124–125). United Electric's president and a former president acknowledged that the company competed with Freeman (A. 84, 131). Customers of both companies have considered them competitors (GX 93, A. Ex. 118–119, GX 94, A. Ex. 121, A. 1437).

2. The district court, however, concluded that "an independent United Electric would not and could not compete with Freeman to any substantial degree" because the "companies have been and are now predominantly complementary in nature" (J.S. App.

[42] United Electric's contract with Commonwealth Edison expired in 1970 (J.S. App. 62a).

61a). The reasons the court gave for this conclusion are either beside the point or not supported by the record.

The court stated that United Electric is a strip mining company and Freeman a deep mining company (J.S. App. 61a). But the record is clear that coal from deep mines and strip mines is competitive (GX 91, A. Ex. 117). Freeman sells metallurgical coal and United Electric does not (J.S. App. 62a). But this amounts to only a small portion of Freeman's sales—about eight percent in 1969 (A. 1530)—and only a small portion of coal production and reserves in the relevant areas.[42]

Similarly, Freeman sells coal dust, a by-product of the production of metallurgical coal, while United Electric sells only "screenings" (*i.e.*, pieces of coal) (J.S. App. 62a). But dust and screenings are competitive products. Both are produced in coal mines, priced according to their BTU content, and shipped to the same customers by the same means for use in the same boilers (A. 1125–1127, 1396). Coal is crushed to dust size or smaller prior to burning (A. 1144–1145); and dust and screenings have an identical consistency as they proceed from the pulverizer to the boiler (A. 263–264). Since a ton of dust replaces a ton

[42] The metallurgical coke industry seeks coal with a maximum of 1.5 percent sulfur and a low ash content (GX 210, A. Ex. 135). In Illinois only about three percent of total coal reserves are estimated as within a range of one to three percent sulfur content, and only about half of those reserves are estimated to average 1.5 percent or less in sulfur content (GX 210, p. 22).

of screenings (assuming an equivalent BTU content), dust consumers would purchase more screenings if dust were not available (A. 1127, 1143–1144, 1164, 1396).

While Freeman's and United Electric's mines are in different freight rate districts (J.S. App. 62a), we have already shown that mines in different districts, including Freeman's and United Electric's mines, can and do compete for the business of the same customers (pp. 42–43, 45–50, 60–61, *supra*).

The court stated that, because of local and federal air pollution controls in the Chicago area, United Electric's Chicago market for its relatively high sulfur coal will ultimately disappear, and the company will no longer be able to compete with Freeman in that area (J.S. App. 62a). The record does not indicate, however, that these pollution controls will preclude the use of all high-sulfur coal. The director of the Chicago Air Pollution Control Agency testified that the applicable ordinance permits the burning of high-sulfur coal when used, for example, in conjunction with low sulfur fuels, or when adequate control devices are installed (A. 496–497). Such control devices are being developed and are expected to be available within four to five years. (A. 1185, 1429). Moreover, utility and industrial coal consumers are building new facilities outside the Chicago metropolitan area (A. 495–496); high voltage transmission lines now permit a utility to locate generating plants considerable distances from distribution centers (A. 1185).

D. THE MERGER CANNOT BE JUSTIFIED ON THE GROUND THAT, BECAUSE OF INADEQUATE RESERVES, UNITED ELECTRIC NO LONGER WAS A SIGNIFICANT COMPETITIVE FACTOR IN THE COAL BUSINESS

1. The claim that the merger would not substantially lessen competition because the acquired company had "inadequate resources" to remain a significant competitor must be tested by the general legal standards that govern the "failing company" defense.

In *Philadelphia National Bank, supra,* 374 U.S. at 363, the Court stated that a merger which gives the merged firm an "undue percentage share" of the market and significantly increases concentration "is so inherently likely to lessen competition substantially" that it must be enjoined "in the absence of evidence clearly showing that the merger is not likely to have such anticompetitive effects." Similarly, in *Brown Shoe, supra,* 370 U.S. at 346, the Court recognized that in merger cases the defendant might present "mitigating factors, such as the business failure or the inadequate resources of one of the parties that may have prevented it from maintaining its competitive position." Appellees have made no contention that United Electric was a "failing company," *i.e.,* one whose "resources [were] so depleted and [for which] the prospect of rehabilitation [was] so remote that it faced the grave probability of a business failure" (*International Shoe Co.* v. *Federal Trade Commission,* 280 U.S. 291, 302). Indeed, they could not possibly make the argument on this record, which shows that the company has been a vigorous and successful competitor in the coal business, whose financial health

was good from at least 1955 to the time of trial (Statement, *supra*, pp. 8–9).

Appellees did contend—and the district court accepted the contention—that because United Electric's coal reserves were inadequate it "could not in the future be an independent, viable competitor of Freeman, or any other midwestern coal producer" (Defendants' Post-trial Br. 80; emphasis omitted); and that since United Electric standing alone could not continue as a competitive force in the market (Post-trial Br. 81–82), its elimination through merger could not substantially lessen competition. We submit, however, that this ruling reflects an erroneous concept of what constitutes the "inadequate resources" (*Brown Shoe*) that a defendant must establish, in order to overcome the government's *prima facie* case.

This Court has not elucidated the concept of "inadequate resources" which, it suggested in *Brown Shoe*, might justify an otherwise illegal merger.[44] It has, however, ruled that the analogous "failing company" defense has a "narrow scope" and can be successfully asserted only in extremely limited circumstances. *Citizen Publishing Co.* v. *United States*, 394 U.S. 131,

[44] Congress has expanded the "failing company" defense in dealing with the banking industry. In the Bank Merger Act of 1966 it provided that an anticompetitive merger nevertheless may be approved if it is found that "the anticompetitive effects of the proposed transaction are clearly outweighed in the public interest by the probable effect of the transaction in meeting the convenience and needs of the community to be served." 12 U.S.C. 1828(c)(5)(B). In creating this new defense Congress recognized that even though a bank might not be "so deeply in trouble as to

139. We submit that any defense based on the alleged inadequate resources of the acquired firm is similarly available only on narrowly circumscribed conditions.

a. The defense of inadequate resources rests on the same economic premise as the failing company defense: that if a firm has ceased to be an economically viable enterprise, its elimination cannot substantially lessen competition because it no longer is a significant competitive factor in the market. In manufacturing and distributing industries, it is difficult to envision a case where the inadequate resources defense could be made. In an extractive industry, however, there may be exceptional situations in which the condition of a firm's resources are such that, apart from the merger, it was about to disappear from the market.

Assume, for example, that a firm which currently produces 25 percent of a particular metal acquires a firm which produces 20 percent of that metal and that the industry is highly concentrated. Under this Court's market structure standards for deciding Section 7 cases, the merger would be *prima facie* illegal (*supra*, pp. 50–60). Further assume, however, that the

---

call forth the traditional 'failing company' defense," if it was "nonetheless in danger of becoming before long [a] financially unsound" institution, the public interest in avoiding the latter condition might outweigh the anticompetitive effects of the merger. *United States* v. *Third National Bank in Nashville*, 390 U.S. 171, 187. Congress, however, has not created any similar exception to the "failing company" defense for the coal industry and certainly has not manifested any intention that the "inadequate resources" theory in *Brown Shoe* should be given a comparable expansion.

acquired firm, although having 20 percent of the market, (1) would exhaust its supply of the metal within a year, (2) could not obtain any substitute source of supply, and (3) had neither the financial resources nor the managerial skills that would enable it to prolong its independent existence through resort to new technology or further exploration. In such circumstances, the merger apparently would not substantially lessen competition because the acquired firm would soon cease operations.

Since Section 7 is concerned with the probable effects of a merger on competition, the failing company defense has focused mainly on the most convincing evidence of inability to continue operations—the imminent likelihood of financial collapse. An "inadequate resources" claim, however, requires a broader and more sophisticated analysis. Where the company is economically sound and not facing immediate financial catastrophe, there are substantial uncertainties with respect to its probable future even if its present supply of raw materials is about to be exhausted. The acquisition of a financially healthy firm in an extractive industry, such as United Electric, means that the firm is unlikely to conduct research and development designed to obtain more efficient use of existing resources or to discover new ones; use of new industrial techniques may permit the extraction of raw materials previously considered unusable and lead to the discovery of new sources of supply. See *infra*, pp. 71–74, and n. 53. Moreover, the longer the time before the re-

sources will be exhausted, the less certain it is that the acquired firm would disappear without the merger.

Thus, although an "inadequate resources" defense invokes the same economic principle as a failing company defense, the inherent uncertainty that a lack of inadequate resources will result in the termination of operations requires an even stronger showing of imminent collapse than is required in the case of an allegedly failing company. Recognizing the differences in the factual showing required to support that claim, we submit that an "inadequate resources" defense must be tested by the general legal standards which this Court has established in "failing company" cases.[45]

b. This Court has made it clear that before a financially ailing firm can be considered "failing" the condition of the firm must be such that there is no realistic prospect of recovery so that were it not for this particular acquisition, the firm would quickly have disappeared from the market. The critical consideration is that there is no reasonable alternative possibility of rehabilitating the firm or keeping it going. Section 7 is concerned with long-range trends and changes in market structure, and the acquisition of an alleged "failing company" would pose no reason-

[45] "The burden of proving that the conditions of the failing company doctrine have been satisfied is on those who seek refuge under it" (*Citizen Publishing Co.* v. *United States*, 394 U.S. 131, 138–139, footnote omitted). In view of the closely-related character of that defense to the inadequate resources defense, we submit that the burden of establishing the latter similarly is on "those who seek refuge under it."

able probability of anticompetitive effect only if that company were otherwise permanently and irrevocably incapacitated. For this reason, temporary difficulties, no matter how serious or substantial, are not sufficient to constitute a failing company defense. Before that defense can be accepted, every reasonable method of economic rehabilitation must have been adequately explored and found unavailable.

Thus, for a company to be "failing" so that its elimination cannot substantially lessen competition, its situation must be so precarious and so hopeless that it is "on the brink of collapse" and its prospects of reorganization or resuscitation must be "dim or nonexistent" (*Citizen Publishing Co.* v. *United States*, 394 U.S. 131, 138). The Court there also pointed out (*ibid.*):

> The failing company doctrine plainly cannot be applied in a merger or in any other case unless it is established that the company that acquires the failing company or brings it under dominion is the only available purchaser. For if another person or group could be interested, a unit in the competitive system would be preserved and not lost to monopoly power.

In *United States* v. *Greater Buffalo Press, Inc.*, 402 U.S. 549, 555–556, the Court recently reiterated that the failing company defense requires a showing that the acquired company was in danger of imminent financial collapse and that the acquiring company was the only prospective purchaser. See, also, *United States* v. *Third National Bank in Nashville*, 390 U.S. 171, 189.

This Court's decisions also indicate that the validity of a failing company defense must be determined as of the time of the acquisition, not as of the time of trial. In *International Shoe*, the acquisition had taken place in May 1921, and the Court focused upon the acquired company's financial condition between 1920 and "the spring of 1921" (280 U.S. at 300). In *Citizen Publishing*, the transaction with respect to which the failing company defense was asserted took place in 1940, and the Court considered the acquired firm's condition as of that date, although the suit was not brought until 1965 (see 394 U.S. at 138). Similarly, in *Greater Buffalo*, the critical time for evaluating the defense was "the year of the sale," not the time of trial (402 U.S. at 555).[*] The reason is that, since the rationale of the failing company defense is that a merger cannot have anticompetitive consequences if the company thereby eliminated was about to disappear anyhow as a significant factor in the market, the company's viability must be determined as of the time of the merger.

For the same reasons, we submit that an "inadequate resources" defense is not available unless, at the

---

[*] In *Federal Trade Commission* v. *Consolidated Foods Corp.*, 380 U.S. 592, 598, the Court stated:

"[T]he force of § 7 is still in probabilities, not in what later transpired. That must necessarily be the case, for once the two companies are united no one knows what the fate of the acquired company and its competitors would have been but for the merger."

See, also, *United States* v. *Continental Can Co.*, *supra*, 378 U.S. at 463; *United States* v. *Penn-Olin Chemical Co.*, 378 U.S. 158, 170, 177; *Federal Trade Commission* v. *Procter & Gamble Co.*, 386 U.S. 568, 577.

time of the acquisition, (1) the acquired company was about to cease operation because it had no reasonable likelihood of obtaining additional raw materials or otherwise solving its supply problem, and (2) there was no alternative way of preserving its existence, such as sale to a purchaser—other than one of its largest competitors—who would undertake to rehabilitate it. Neither condition was satisfied in this case, and accordingly the "inadequate resources" defense should have been rejected."

2. The district court did not find, and the record does not show, that at the time of the acquisition United Electric was about to go out of business and could not be rehabilitated.

a. The district court held that United Electric cannot "continue operations beyond the life of its present mines" and "standing alone, cannot contribute meaningfully to competition" (J.S. App. 63a, 64a). It stated that the government "failed to come forward with any evidence that such reserves are *presently* available" (*id.*, 63a, emphasis in original), and that "virtually all of the economically mineable strip reserves of United Electric have been sold under long-term contracts, and United Electric has neither the

" Although we did not frame our argument in these terms in our jurisdictional statement, we argued there, as we do here, that the district court erred in considering only "whether the acquired firm could survive *at the time of trial* as a competitive entity, without also (and more significantly) determining the competitive potential cut off by the acquisition" (J.S. 22, emphasis in original). See, also, J.S. 20, 24. Similarly, we stated in our Brief in Opposition to Motion to Affirm (p. 5) that "appellees' claim that UEC is a self-liquidating company is essentially an affirmative defense, akin to the failing company defense * * *."

possibility of acquiring more nor the ability to develop deep coal reserves" (*id.*, 65a).

These findings do not sustain an "inadequate resources" defense because they do not relate to United Electric's reserves and viability in 1959, when Material Service took effective control of the company, or in 1967, when General Dynamics became the company's sole shareholder (J.S. App. 8a–9a). There is no finding, and the record does not show, that in 1959 or 1967 United Electric was about to go out of business as a consequence of depleted reserves. Nor is there any finding that virtually all of United Electric's strip reserves were committed in either of those years; the finding that 48 of 52 million tons of those reserves were committed (J.S. App. 9a, 65a) related to the time of trial (see note 7, *supra*). Similarly, although the court found that, at the time of trial, United Electric could not reasonably expect to acquire additional economically mineable strip reserves, it did not find that it could not have acquired such reserves in 1959 or 1967. Indeed, the record shows that between 1959 and 1970 United Electric did enhance its reserves at existing mines.[48] Moreover, other coal producers acquired new strip reserves in Illinois and Indiana after 1960 and were actively prospecting for coal reserves even at the time of trial (A. 1489–1490).[49]

---

[48] Although it mined 50 million tons of coal from 1959 to 1969, the estimated reserves dedicated to existing mines declined only about 18 million tons (DX 60, A. Ex. 517, 540, 544–561).

[49] Commonwealth Edison was itself acquiring central Illinois strip reserves which it expected to use (A. 1422, 1430, 1442).

The district court also found that United Electric has no experience in developing deep coal reserves and no "likelihood of acquiring it" (J.S. App. 61a). But it did not consider whether, had Freeman (a deep coal producer) not acquired the company, United Electric could have acquired the necessary expertise, either by training its own personnel, hiring already experienced personnel, entering into a joint venture of limited duration with a deep coal company, or even acquiring a small deep coal producer.

Appellees have never disputed that ample deep coal reserves are available in the Eastern Interior Coal Province. Humble Oil was able to acquire 3 billion tons of deep reserves in 1965 and 1966 (DX 61, A. Ex. 577, A. 849). The record shows that United Electric has had both the financial resources and general coal marketing experience necessary to enter deep mining,[50] that at least one company (Humble Oil) made a *de novo* entry into deep mining after 1964,[51] and that one strip mining company (Ayrshire Collieries) acquired an existing small deep mining company in the 1950s and used the acquired firm's staff as

[50] The company's financial health has for many years been excellent (p. 9, *supra*). In 1968, it had $10.7 million in working capital, a net worth of $26.9 million, and no long term debt (GX 34, A. Ex. 40). A past president of United Electric and of Freeman estimated that the cost of opening a deep mine at Round Prairie Field, where United Electric has acquired deep reserves, would be $6.5 million to $7.5 million (A. 94).

The market for United Electric's strip-mined coal would be available for deep-mined coal (A. 1493, 1693).

[51] Humble constructed a deep mine at a cost of between $10 million and $20 million (excluding the cost of reserves); the mine is expected to produce three million tons of coal per year for 20 to 30 years (A. 849).

the nucleus of a new deep mining organization (A. 1490–1491).[52]

It is a well-known fact in the American economy, of which this Court may take judicial notice, that firms in the extractive industries regularly and constantly seek and obtain new sources of supply. Oil companies and natural gas companies are searching for new oil and gas reserves; the record shows that coal companies, too, vigorously pursue this policy of exploration and acquisition of additional reserves (A. 1498). Moreover, research into new methods of extraction often succeeds in rendering usable reserves which previously could not have been economically mined.[53] It is hard to believe that a firm as large, important, and financially strong as United Electric, which both in 1959 and in 1967 was one of the major coal companies in the midwest, would idly sit by and allow its entire coal business to disappear because its existing coal reserves were becoming exhausted. To the contrary, the realities of economic life indicate that, had United Electric remained an independent company, it, like other companies similarly situated, would have vigorously

[52] Although the Ayrshire venture was not successful, an official of that company testified that the problems were unrelated to extractive expertise: "I rather doubt that anyone could have made a profitable operation out of it" (A. 1491).

[53] As a result of the technological changes in methods of extraction, the depths at which strip mining may occur and the proportion of ground cover to coal seam thickness (overburden ratio) which can be economically removed have changed so that mining of previously unusable coal deposits has become feasible (A. 57, 400, 532, 645–646, 689–690, 1489, 1495, 1532, DX 49, A. Ex. 403, GX 632, A. Ex. 158).

pursued a policy of obtaining additional reserves to enable it to continue its substantial business as its existing reserves were depleted.

b. Similarly, the district court did not find, and the record does not show, that, at the time of acquisition, there was no possibility of solving United Electric's problems of a lack of adequate coal reserves other than by eliminating the company. Cf. *Citizen Publishing Company, supra.* Indeed, the record does not indicate that United Electric sought or agreed to the merger because of concern that it was about to go out of business because of a lack of reserves. In light of the experience of other companies in entering into deep mining of coal without prior experience and the substantial deep mining reserves available in the area where United Electric operates (see *supra,* pp. 71–73), this merger could not be justified by reference to United Electric's "inadequate resources" unless and until that company had explored all possibilities but found them unavailable.

CONCLUSION

The judgment of the district court should be reversed, and the case remanded for the entry of an appropriate decree.

Respectfully submitted.

Question presented	1
Statement	2
Summary of argument	5
Argument:	
I. Substantial evidence supported the District Court's determination that the Freeman-United Electric combination has not led and is not likely to lead to a substantial lessening of competition	12
A. United Electric is not a competitive factor	12
1. Reserves are the key factor in measuring a coal producer's market strength	13
2. United Electric does not have the coal reserves to be considered a competitive force	17
3. United Electric has neither the possibility of acquiring more strip reserves nor the ability to develop deep-coal reserves	20
4. Other industry forces at work make it inconceivable the combination could have an adverse effect on competition	29
B. The combination of Freeman-United Electric did not eliminate actual or potential competition between them	36
C. Evidence from numerous knowledgeable industry representatives confirmed that the Freeman-United Electric combination has not led and is not likely to lead to a substantial lessening of competition	42
D. There remains no other justification for the Government's complaint	46
II. The District Court committed no error in declining to decide the case solely upon the structural data submitted by the Government	48
A. The decision below did not turn on the subsidiary questions of market definition	49

ARGUMENT—CONTINUED

PAGE

B. The District Court correctly rejected the market definitions urged by the Government 53

C. The Government's structural data was not a fair measure of the competitive impact of the combination 64

III. The fourth question presented by the Government is untimely, inconsistent and without merit 69

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, and FREEMAN COAL MINING CORPORATION, APPELLEES

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

BRIEF FOR APPELLEES

QUESTION PRESENTED

There is really only one question presented by this case:

Whether the District Court's conclusion, "upon the basis of reliable, probative and substantial evidence contained in the record," that the longstanding affiliation of two coal producers challenged in this action does not violate Section 7 of the Clayton Act is clearly erroneous. (J.S.App. 66a.)

The subsidiary questions of market definition which the Government urges as presenting additional questions for

review, while correctly decided by the District Court, were neither critical to, nor controlling of, the decision below. The District Court specifically held in this regard that no violation of Section 7 would be found "even were this court to accept the Government's unrealistic product and geographic market definitions." (J.S.App. 66a.)

The other question which the Government now states is presented was not raised in its Jurisdictional Statement. There the Government urged that this Court conduct a plenary review of the trial record to determine whether there was evidentiary support for the trial court's findings with respect to the inability of the acquired company to secure the strip coal reserves or expertise in the mining of deep coal reserves necessary for it to be a viable competitive force.[1] Having now taken a hard look at the record and seen that it is dead against them, Government counsel handling the appeal state that they have "shifted." They now wish to present for review—instead of the original question—the question whether the District Court tested United Electric's competitive demise at the proper time and under correct standards. Far from presenting a serious question, however, the Government's arguments on this score are nothing more than a contrived afterthought, lacking in substance and totally at odds with their position in the District Court. They should be rejected out of hand, if not disregarded completely. See Supreme Court Rule 40(1)(d)(2).

STATEMENT[2]

The combination of Freeman Coal Mining Corporation and The United Electric Coal Companies which the Gov-

[1] See Jurisdictional Statement, Question 4 and pages 21-24. See also Brief for the United States in Opposition to Motion to Affirm, pp. 3-8.

[2] Record references to the facts summarized here appear in the Argument portion of this brief where they are discussed in (cont.)

ernment seeks to undo is nearing the close of its second decade, and United Electric itself is at the end of its competitive life. This longstanding affiliation had its inception in 1954 when the Freeman interests purchased more than 10 percent of United Electric's stock, and was formalized in 1959 when five new directors were elected to United Electric's nine-man Board, a new president was chosen as chief executive officer, and the president of Freeman became Chairman of United Electric's Executive Committee as well. The affiliation was disclosed to both the public and the Government from the outset, and in 1960 the Antitrust Division of the Department of Justice was furnished information with respect to the common stock ownership of Freeman and United Electric, but took no action. (J.S. App. 7a-8a.)

By the mid-1950's United Electric found itself faced with a critical reserve problem. While uncommitted coal reserves are, of course, the life blood of any coal producer, the company's premerger management had unfortunately not provided for its future. United Electric recognized the need to stem its deteriorating competitive position and that a merger with another coal producer was the only realistic way to achieve this. Accordingly, prior to its affiliation with Freeman, the company attempted, without success, to merge with or acquire a number of other coal companies.

---

detail. The record in this case, as the trial court noted, "consists of more than 7,500 pages of trial transcript and deposition testimony, and more than 800 trial and deposition exhibits, containing in excess of 10,000 pages." (J.S.App. 2a, n.2.)

In the Proposed Findings of Fact and Conclusions of Law submitted by them following the trial, the defendants attempted to summarize and set forth in a concise and organized manner those portions of the trial record material to the issues raised in the complaint—and subject to review by this Court. Accordingly, for the Court's convenience, these Proposed Findings (hereafter "DPF") have been reprinted in full in the Joint Appendix, as have most of those portions of the record cited therein.

After its affiliation with Freeman, United Electric's land policies were changed, and an aggressive reserve acquisition program pursued. By that time, however, the strip reserves necessary for United Electric to remain a viable competitive force in the Midwest were controlled by other producers. There was also no prospect for United Electric remaining viable through entry into deep mining. Since at least 1930, and continuing to date, United Electric has had neither the equipment, personnel nor expertise required for successful entry into deep mining; it was strictly a strip mining company and was destined to remain so. In sum, whether viewed from the standpoint of 1959, or the date of the filing of the complaint, or the time of trial, United Electric was not going to survive as a significant competitive force.

The affiliation of Freeman and United Electric brought together "predominantly complementary rather than competitive producers." (J.S.App. 65a; see also J.S.App. 61a.) United Electric is a strip mining company producing low quality, high sulphur coal, while Freeman is a deep mining company producing high quality, low sulphur coal. The operations of United Electric are located in different ICC-designated Freight Rate Districts[2a] from those of Freeman, and as the Court pointed out, "responses to the subpoena questionnaire sent to midwest coal consumers demonstrated that each Freight Rate District serves a distinct and definable area, as did the testimony of producers and consumers." (J.S.App. 57a.)

Not until September 22, 1967 did the Government file its complaint alleging that the Freeman-United Electric affilia-

---

[2a] The Interstate Commerce Commission has designated various coal producing areas within Illinois, Indiana and west Kentucky as "Freight Rate Districts." See DPF 286-287, A.964. The history and functions of the Freight Rate Districts involved in this litigation are discussed in *Ayrshire Collieries Corp.* v. *United States*, 335 U.S. 573, 576 (1949).

tion violated Section 7 of the Clayton Act and praying that General Dynamics be required to divest itself of its interests in United Electric. On the basis of two and a half years of pretrial discovery, a month long trial, and the submission by both sides of pretrial proposed findings and extensive post trial proposed findings, briefs and replies, a distinguished antitrust trial judge[2] reached the conclusion, after an "evaluation of the massive quantity of evidence submitted by the parties," that the challenged combination "has not led, and is not likely to lead to a substantial lessening of competition." (J.S.App. 2a, 65a.)

SUMMARY OF ARGUMENT

The District Court's determination that the challenged combination does not violate Section 7 turned on a host of disputed and complex *factual* issues, each of which was resolved squarely against the Government on the basis of abundant evidence. It was this record evidence that compelled the court below to recognize that:

First, since virtually all of United Electric's economically mineable strip reserves have been sold under long-term contracts, and it has neither the possibility of acquiring more nor the ability to develop deep coal reserves, the Company is not a significant competitive force. (J.S.App. 65a-66a.) In fact, it was United Electric's critical reserve position which led it in the 1950's to seek affiliation with another coal producer. (J.S.App. 8a, n.7.)

Second, because of differences in the location and types of their mines, in the quality of their coals and in the nature

[2] Chief Judge Robson, who heard all of the evidence and spent nearly two years fashioning his decision, was the coordinating judge in the civil electric antitrust cases, an original member and the first chairman of the Judicial Coordinating Committee for Multiple Litigation and one of the principal architects of the Manual for Complex and Multidistrict Litigation.

of their transportation routes, Freeman and United Electric have long been predominantly complementary rather than competitive producers, and an independent United Electric would not and could not compete with Freeman to any substantial degree. (J.S.App. 61a-62a, 65a.)

Third, because it faces vigorous competition from other large coal producers, the challenge of competing fuels, and large and sophisticated buyers across the bargaining table, a combined United Electric-Freeman neither has led, nor is likely to lead, to a lessening of competition. To the contrary, the testimony of knowledgeable industry witnesses confirmed that the combination had no anticompetitive effect. (J.S.App. 65a.) The Government, despite a diligent search, was unable to find a single customer or competitor who thought otherwise, although at the time of trial, the affiliation was well into its second decade.

Accordingly, the Government was forced to present a theoretical structural case, relying largely on statistical data. This Court has made it clear, however, that while statistical data is important, "only a further examination of the particular market—its structure, history and probable future—can provide the appropriate setting for judging the probable anti-competitive effect of the merger."[4] *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 322 n.38 (1962). It was on the basis of precisely such an examination, involving a careful assessment of *"all* of the evidence" (J.S.App. 2a, 18a, 53a, 61a, 64a, 66a), that the District Court concluded that the challenged combination did not offend Section 7.

[4] This is particularly true where, as was the case below, the statistics in question fail "to measure market strength or competition as it exists." (J.S.App.59a.) The myriad deficiencies in the statistics proffered at trial by the Government are catalogued in Defendant's Proposed Findings 374 through 385, A.989-92, and discussed at pages 64 to 69, *infra*.

I.

As is fully detailed in the trial court's opinion (J.S.App. 11a-27a), the change in the composition and character of those consuming coal since World War II has had a substantial impact on coal producers. As the diesel engine replaced the steam locomotive, and as natural gas and oil displaced coal in the home and industrial heating markets, coal ceased to be a product consumed by a large number of relatively small volume users.[5] The principal coal consumers today are the large utility companies which constitute coal's only remaining significant market. This market is predominantly served by large suppliers under contracts of five to fifteen years' duration and longer.

Uncommitted coal reserves are the essential key to competing for this business. It is such reserves—and not current production, profits, or cash flow—which provide the measure of a coal producer's viability in competing against the reserves of other coal companies and against the resources of suppliers of alternative fuels.

The evidence at trial showed, as the District Court found, that "virtually all of the economically mineable strip reserves of United Electric have been sold under long-term contracts, and United Electric has neither the possibility of acquiring more nor the ability to develop deep coal reserves." (J.S.App. 65a.)

Initially, the Government's principal contention on the reserve issue was that the coal reserves already owned by United Electric in the Industry and Round Prairie fields

---

[5] It is, of course, this dramatic change in the nature and number of coal consumers which accounts for the progressive disappearance of small coal producers. In light of this, the Government's analogy to the decline in the number of single store grocery operations found significant in *United States* v. *Von's Grocery Co.*, 384 U.S. 270 (1966), rings false, as its own economist recognized at trial. (Folsom A.1706.)

provided the key to a successful future, since they could be profitably developed by a "competent and unfettered management." (Government Supplemental Interrogatory Answers 46 and 47; DX 46, p. 40, A.Ex.334.) Subsequently, however, the Government confessed to the District Court that it was "inclined to agree" with the defendants' representation that "as of today they are not commercially valuable." (Transcript of Pre-trial Conference of October 3, 1969, p. 23, A.874.)

Retreating from its rose-colored view of Industry and Round Prairie,[6] the Government urged next that the simple solution to United Electric's shortage of commercially recoverable strip reserves was for the company to buy more. Geologists, mining engineers, company officials, other producers, and even its own economist, however, all testified to the fact that such reserves are unavailable for acquisition. (J.S. App. 63a.)

Recognizing the weakness of its secondary position, the Government announced a third: United Electric could survive by making a grass-roots entry into the deep mining of coal. Again, however, the evidence demonstrated that its experience as a profitable strip miner would not enable United Electric successfully to make a grass-roots entry into deep mining. (J.S. App. 61a.)

Confronted with these facts, the Government's Brief here announces yet a fourth position—the eleventh hour claim that evidence on the reserve issue related to the wrong time period. Once more, however, the record is to the contrary; it contains a wealth of evidence confirming that United Electric was in the same liquidating posture in 1959 as it was at the time of trial.

---

[6] Indicative of the extent of this retreat is that while the Industry and Round Prairie "issues" loomed large in the Jurisdictional Statement (pages 22-24) and Brief in Opposition to Motion to Affirm (pages 5-8), they are not even mentioned in the Government's most current brief.

This competitive demise of United Electric because of its critical reserve position is particularly significant when considered against the backdrop of other factors affecting coal producers. In determining what fuel to buy, for example, energy consumers can and do consider a wide variety of alternatives including, among others, coal, natural gas, oil, nuclear energy and hydropower. As is fully detailed in the opinion (J.S.App. 27a-53a), this was confirmed, not only by the responses to the subpoena questionnaire issued by the trial court, but by the testimony of a host of knowledgeable industry witnesses—including a representative cross-section of midwest utilities. Indeed, the evidence is clear that the present level of keen interfuel competition will intensify in the years ahead as public concern over the environmental impact of air pollution and strip mining increases and as technology for additional fuel sources continues to develop.

Other factors pertinent to an analysis of the likely competitive effects of the combination were disclosed in the evidence speaking to the size and sophistication of today's coal consumer—the electric utility. These utilities typically regard fuel purchasing as a top executive responsibility and purchase boiler fuel in such quantities that they can and do play the suppliers of one energy source against another, as well as one coal producer against another.

Such a market place stands in sharp contrast to the grocery market considered in *United States* v. *Von's Grocery Co.*, 384 U.S. 270 (1966), or the beer market in *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 (1966). There, millions of individual consumers, each making relatively small purchases, had no bargaining power at all. To analogize the purchase and sale of 10 million tons of coal under a twenty year contract to the purchase and sale of a bag of groceries or a six-pack of beer belies common sense.

II.

The nature and extent of competition among coal producing companies is determined by such factors as the requirements and location of specific consuming facilities *vis-a-vis* the production capability and location of specific mines, and the available interconnecting transportation facilities. These "economic realities" concerning the role which both mine location and coal characteristics play in the competitive market place are especially significant to this litigation, since "[c]rucial to the Government's case is proof that United Electric and Freeman are actual or potential competitors." (J.S. App. 61a.)

United Electric's strip mines are located in different Freight Rate Districts and produce a different type of coal from the underground mines operated by Freeman. The results of the subpoena questionnaire issued by the District Court, as well as the testimony of consumers and producers, confirmed the significance of coal characteristics, that Freight Rate Districts serve essentially separate and distinct areas, and that Freeman and United Electric are predominantly complementary producers. This evidence compelled the conclusion that "an independent United Electric would not and could not compete with Freeman to any substantial degree." (J.S. App. 61a.)

III.

In the final analysis, what the Government really despairs of is nothing more than the trial court's refusal to accept its invitation to substitute a simple, but wholly inappropriate, statistical divining rod for a painstaking and thoughtful analysis of the "reliable, probative and substantial" evidence reflected in more than 17,500 pages of testimony and exhibits. It should be emphasized in this regard that the trial court did not substitute some *other* statistical divining

rod for that urged by the Government. Rather, the District Court's conclusion that "no adverse consequences with respect to competition were shown either to have occurred or likely to occur" (J.S.App. 64a) was based on a meticulous two-year review and evaluation of all of the evidence relevant to such a determination.

In making this assessment, there was simply no way that the vigorous interfuel competition that exists in the market place could be ignored. The District Court refused to blind itself to these competitive facts-of-life and followed this Court's admonition to "recognize competition where, in fact, competition exists." *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 326 (1962). See also *United States* v. *duPont & Co.*, 351 U.S. 377 (1956). Similarly, the District Court recognized that far more important than the particular labels identifying the geographical outbounds of the sections of the country, was granting full recognition to the extent to which the merging parties do and do not compete in analyzing the "crucial question" of the likely effects of their combination on competition. *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, 549-50 (1966).

Taking full account, then, of such "commercial realities" as the vigorous interfuel competition that exists in the market place and actual coal distribution patterns, the court below quite properly concluded that the longstanding Freeman-United Electric affiliation posed no threat to competition, and that this was true whatever the framework within which it was tested. Accordingly, the District Court, on the basis of the evidence presented at trial and detailed in its lengthy opinion, concluded with the specific holding that the challenged combination would not violate Section 7 "even were this court to accept the Government's unrealistic product and geographic market definitions." (J.S.App. 65a-66a.)

ARGUMENT

I.

SUBSTANTIAL EVIDENCE SUPPORTED THE DISTRICT COURT'S DETERMINATION THAT THE FREEMAN-UNITED ELECTRIC COMBINATION HAS NOT LED AND IS NOT LIKELY TO LEAD TO A SUBSTANTIAL LESSENING OF COMPETITION.

After "evaluation of the massive quantity of evidence submitted by the parties", the District Court below concluded that the Freeman-United Electric combination did not violate Section 7 of the Clayton Act. (J.S. App. 2a.)[7] As will be shown, this determination turned on resolution of a host of factual issues peculiarly within the province of the trier of fact and decided squarely against the Government.[8] These findings based on "reliable, probative and substantial evidence contained in the record" (J.S. App. 66a.) were not "clearly erroneous" and should be affirmed. *United States* v. *du Pont & Co.*, 351 U.S. 377, 381 (1956); Fed. R. Civ. P. 52(a).

A. United Electric Is Not A Competitive Factor.

At page 65 of its Brief, the Government itself recognizes the indisputable premise "that if a firm has ceased to be an

Except where otherwise noted, emphasis has been supplied throughout.

[8] A full description of the nature of the evidence, the witnesses appearing, and the type of documents in the record, appears at DPF 9-48, A.887-99.

economically viable enterprise, its elimination cannot substantially lessen competition because it no longer is a significant competitive factor in the market." Indeed, the Government's own trial economist, on three occasions during his testimony, ventured his opinion that, without coal reserves or prospects to develop them, continuation of the combination would not be "adverse to competition" and United Electric "is not going to be in that situation a viable competitive force in this market, even if it is divested from General Dynamics." (Folsom A.1711, 1707-08, 1715.) This was precisely the reasoning followed by the District Court in its finding that the combination does not adversely affect competition because, in part, "United Electric can hardly be considered a competitive force" and "cannot contribute meaningfully to competition." (J.S. App. 63a, 64a.)[9]

This determination was made on the basis of a wealth of record evidence on key *factual* issues at trial. This evidence established that: (1) Because the utility market will undoubtedly remain the only substantial outlet for coal production, the key factor determining a producer's strength is coal reserves; (2) United Electric does not have the coal reserves to be considered a competitive force; and (3) United Electric has neither the possibility of acquiring more strip reserves nor the ability to develop deep coal reserves. In addition, (4) other industry forces at work make it inconceivable the combination could have an adverse effect on competition. (J.S. App. 63a-65a.)

1. Reserves Are The Key Factor In Measuring A Coal Producer's Market Strength.

Among the District Court's uncontested findings was that "[a]s a result of market losses to other forms of energy, the

[9] As is discussed hereinafter, pages 69 to 76, these findings were based on facts dating back to the early 1950's and not merely conditions prevailing at the time of trial.

utility market has become the mainstay of coal production." (J.S. App. 12a; Gov't. Brief, p. 4.) The evidence was that this market "will undoubtedly remain the only substantial outlet for coal production."[10]

In view of this, the focus of the court's scrutiny of the combination's effect on consumers centered on the utility market, as did the evidence adduced by both sides.[11] As a result, the trial court carefully analyzed the way in which coal was bought and sold in this market, and the manner in which coal producers competed for the custom of electric utilities.

Because of the need to have assurances of a steady supply of the required quantity of coal over a long period of time, and at an established cost, it was found that utilities typically arrange long-term contracts for all or at least a major portion of the total fuel requirements for the life of a generating plant.[12] As the court noted with respect to the coal purchased by Midwest utilities in 1967:

---

[10] J.S. App. 64a; see DX 216, A.Ex.1215; Gallagher Dep.Ex.1-3, A. Ex.1416; Steiner Dep.Ex.2, ¶ 2, A.Ex.1828-29. See, generally, DPF 146-166, A.925-30. The Government states at page 26 that "[t]he market for coal is therefore effectively confined to electric utilities and other large fuel users, such as cement manufacturers . . . ." However, the trial court reviewed the continuing "trend of industrial consumers away from coal" (J.S.App. 30a-32a) and the evidence was that the kilns of cement companies are fired by gas, oil or low-sulphur coal which United Electric cannot produce. See Steele A.1281; Morris A.1151-52; DX 68, 69, 70, 74, 75, 76, 78, 242, A.Ex. 587, 588, 590, 600, 603, 604, 608, 1291.

[11] This is not to say the smaller consumer segments were not scrutinized as well. See J.S. App. 30a-32a; see, generally, DPF 205-210, A.941-43; DPF, 317, 319, 324, 326, 331, 333, 338, 340, A. 972-78; Redard A.568; H. E. Petersen A.365; Stipulated Testimony of Knecht (A.851), Sinclair (A.838), Sant (A.870) and Hemminger (A.869).

[12] See Gamble A.1336-37, 1341-43; Corey A.1417-19; Hill A.1302-05; Tomey A.1111-13; Davis A.1200-01; Schotters A.640-41; Nicosin A.516-17; Ward A.551-52; Gerber A.774-75; DX 86, p.3, A.Ex.736; DX 93, A.Ex.889.

> "[*I*]*t is undisputed that approximately 76 percent was purchased under contracts of five years or longer and 43 percent was purchased under contracts of 15 years or longer duration.*" (J.S. App. 22a; emphasis, the court's.)

Before entering into such long-term contracts, it was found, and admitted by the Government, that a utility normally seeks independent, geological verification of the existence and size of the supplier's coal reserve to assure itself that the supplier is capable of supplying the required quantity.[13] One utility executive emphasized that when a utility is arranging for a fuel supply for a modern generating station representing an investment of several hundred million dollars, it wants "to know that the people you sign a contract with are able to produce on their end of it." (Tomey A.1113; see also Gamble A.1343.)

In the wake of this evidence, it was found that the competition for the business of utilities was not for the sale of coal already produced, but for long-term contracts:[14]

> "Because of the trend toward long-term contracts and away from spot purchasing, competition in the electric utility market is not continuous in the sense that coal producers seek new orders from a given facility on a daily, monthly or even annual basis. Rather, competition tends to be a 'one time thing.' Once the initial coal contract is executed, competition to satisfy the coal requirements of a particular plant is effectively precluded for an extended period of time amounting to as

---

[13] J.S. App. 20a-21a; GRF, p. 48. See Hill A.1309; Gamble A. 1343; Wood A.1193; Steele A.1278-79; DX 86, p.4, A.Ex.737.

[14] This Court has recognized the wisdom of such long-term contracts: "In the case of public utilities the assurance of a steady and ample supply of fuel is necessary in the public interest." *Tampa Electric Company v. Nashville Electric Co.*, 365 U.S. 320, 334 (1960); see also the dissenting opinion of Judge Weick in the Court of Appeals' decision in that case, 276 F.2d 766, 776 (6th Cir. 1960).

much as 15 years or even the full life of the plant." (J.S. App. 23a-24a.)

In this rivalry, it is obvious that a coal producer without sufficient reserves cannot effectively participate. This proposition was repeatedly confirmed by the experts, consumers and producers who testified,[15] and was recognized by the Government itself in fashioning the consent decree entered in *United States* v. *Peabody Coal Co.*, 1967 Trade Cas. 84,376 (N.D. Ill. 1967). (DX 84, A.Ex.640.) Central to that decree were the provisions requiring Peabody to divest itself of an operating coal business having no less than 120 million tons of reserves and prohibiting Peabody, for five years, from acquiring more than 5 million tons of coal reserves per year from any other producer.

In sum, it is beyond dispute that the critical determinant of whether a coal company can offer effective competition as a supplier is the level of verifiable, substantial and uncommitted coal reserves under its control. As one utility executive put it:

> "[I]n the long range competitive picture, one of the big things is to assure ourselves of the proper reserve situation. We don't go into contracts with those or consider them competitive under this situation, unless they have the reserves to back it up and we can count on them down the road." (Wood A.1178. See also Wood A.1191-92; Corey A.1419-20; Davis A.1213; Steele A.1274-75; Schotters A.640-41.)

On the basis of all the evidence, the trial court was undoubtedly correct in its determination that coal reserves

---

[15] Sherwood A.1373-74, 1377; Folsom A.1706; Steiner A.1576-77; Tomey A.1111-14; Moser A.1391; Steele A.1267-69, 1278-79; Wood A.1177-79, 1187-88, 1193; Davis A.1200-01, 1204, 1224-25, 1227-28; Camicia A.1370-71; Abrahamson A.672; Morris A.101-02, 122-23; Steiner A.799-802; DX 26, A.Ex.249; DX 77, A.Ex.607; DX 86 (pp.3-5), A.Ex.736-38; DX 112, A.Ex.1015.

were "the key factor in a coal producer's market strength." (J.S. App. 65a.)

2. United Electric Does Not Have The Coal Reserves To Be Considered A Competitive Force.

United Electric's present rank is next to last in coal reserves (regardless of mineability) among the ten "leading" producers identified by the Government.[16] In addition, United Electric was found to control *less than one percent* of the total Midwest reserves controlled by all 37 coal producers in Illinois, Indiana and western Kentucky. (DX 61, A.Ex.577; GX 72, A.Ex.91; GX 85, A.Ex.98.)

Of the six mines which United Electric operated in 1948, four have since been closed, as have two others opened in the interim. The Mary Moore mine lasted only 10 years and closed in 1965 upon the exhaustion of strippable reserves earlier than predicted.[17] The Company's Cuba mine, opened in the 1920's, was closed in 1971[18] as the trial court had anticipated; the Banner mine, opened in 1960, will close in the fall of 1973, two years *earlier* than both the defendants and the court had expected. (J.S. App. 7a; DX 60(d), A.Ex. 568.)

Typical of the wide gulf between fact and the Government's view of things that has characterized these proceedings, the Government denied that the Cuba and Banner mines would shortly close (GRF, p. 8), and blithely asserted that "UEC personnel have drastically underestimated the remaining coal reserves around UEC mines." (GPB, p.

---

[16] Companies producing annually more than 300,000 tons in Illinois or more than 1,000,000 tons in the Midwest were defined by the Government as "leading" producers. See note 1 to both GX 72 and GX 85, A.Ex.91, 99.

[17] See Morris A.1077-78.

[18] See 1971 Annual Coal, Oil and Gas Report, Illinois Department of Mines and Minerals, pp. 18, 24-25.

129.) They contended that Banner would last at least another seven and a half years, and that substantial additional reserves around the mine would undoubtedly be acquired. In fact, the Government urged that *all* of the reserve fields of United Electric had additional mineable coals which defendants had not included in their estimates. (*Id.* at 128-33.) The trial court decided this head-on factual controversy squarely against the Government, preferring, as it did throughout, the views of knowledgeable, experienced coal mining personnel to the lay speculation of Government counsel.

The fact remains, as was found, that United Electric will shortly be down to two mines; that its mineable reserves stood at 52 million tons at the time of trial and that *"all but 4 million tons of the economically recoverable coal reserves of United Electric have been sold under long term contracts"*—the equivalent of about nine months' production. (J.S.App. 9a; emphasis, the court's; see DX 63, A.Ex.579.) Here again, the latter fact was denied by the Government at trial and the assertion is repeated here. The present claim (Gov't. Brief, p. 10, n.7) that 11 of the 52 million tons shown on Defendants' Exhibit 63 are not in fact committed because they are only in "negotiation," simply overlooks the trial testimony of the president of United Electric. Frank Nugent testified that since the exhibit had been prepared, one of the contracts involving this tonnage had actually been signed, and agreement reached on all essential terms in the two others. (Nugent A.1519-20.)

If any doubt remained that United Electric had reached the end of its reserves, it was dispelled by the evidence that United Electric's plight was well known within the industry, beginning in the late 1950's. For example, the president of a utility that had been purchasing coal from United

Electric for more than 25 years testified that "a number of years ago I reviewed with our operating people, our production people, the problem that we saw on the horizon, which was the diminishing reserves situation with United Electric." (Steele A.1268-69.)

The record abounds with this type of evidence. United Electric had been advised by some of its customers that it was no longer considered a competitor for any future business,[19] and a contract extension proposed by United Electric in 1965 was returned unsigned with the customer's admonition that it "would be meaningless in view of the limited Fulton County reserves that are controlled by your Company." (DX 26, A.Ex.249.) Other internal documents of the company, antedating the filing of the complaint, confirmed United Electric's debilitated reserve position. (See DX 23, A.Ex.241; DX 112, A.Ex.1015; Nugent Dep. Ex. 35, p.3, A.Ex.1788.)

Finally, the Government's cross-examination of A. H. Davis, President of Central Illinois Light Company, one of United Electric's major customers, provides a succinct commentary on the critical nature of United Electric's reserve problem:

> Q. "So, are you in any position to say that if United Electric and Freeman were merged, that they would have no effect on CILCO in the future?"
>
> A. "Well, we have studied the United Electric reserves, Mr. Sims, and we just can't see where United Electric has the reserves to be a factor in the coal business, as far as we're concerned." (Davis A.1213.)

---

[19] See DPF 88-89, A.909; Morris A.1065-66, 1138-41; Steele A.1268-69, 1278-79; Wood A.1177-79, 1193; Davis A.1204, 1224-25; Moser A.1391; Abrahamson A.672; Morris A.101-06; DX 77, A.Ex.607; DX 112, p.8, A.Ex.1016.

3. United Electric Has Neither The Possibility Of Acquiring More Strip Reserves Nor The Ability To Develop Deep Coal Reserves.

Strip Reserves. The finding by the trial court that "United Electric's coal reserve prospects for the future are singularly unpromising" (J.S. App. 63a) resolved against the Government another deeply disputed fact in the case. As with the other pivotal factual issues, this finding was based on a wealth of credible, competent evidence. The trial court had before it the testimony on the subject of three expert geologists (one a high government official), evidence from coal producers (including one called to the stand by the Government itself),[20] the testimony of coal consumers[21] and the testimony and documents of the defendants.[22]

Specifically, the report prepared by expert geologist John Organ[23] concluded that "such economically mineable strip reserves as exist within the Illinois basin [Illinois, Indiana and west Kentucky] are under the control of existing producers, and . . . such other strippable acreage that has not been acquired holds no competitive promise." (DX 88, A.Ex.796.) Comparably, the Principal Geologist of the Illinois State Geological Survey stated that "[s]o intense has been the interest in the more favorably situated strip

---

[20] Sherwood A.1373-74; Hopper A.1503; Organ A.686-89; Nugent A.62; Stipulated Testimony of George H. Shipley, A.848.

[21] Schotters A.648-49; Dorrance A.394.

[22] Morris A.1137; Ames A.1454; Thorson A.1167; Camicia A.1368-70; Camicia A.93; Nugent A.57-62; Inman A.199-200, 202-03; DX 23, A.Ex.241; DX 112, A.Ex.1015; Nugent Dep. Ex. 35, p.3, A.Ex.1788.

[23] The Government admitted that Mr. Organ's principal occupation since 1932 had been the exploration or acquisition for others of coal lands and mining rights, that he had been responsible for the development of numerous strip coal fields and had made on-site investigations in virtually every coal producing county in Illinois, Indiana and west Kentucky. See DPF [redacted], A.894, and GRF, p.3.

reserves, that I do not know of any prime acreage that is not now under control." (DX 34, A.Ex.259.)

An exhaustive analysis prepared by Paul Weir Company (DX 87, A.Ex.751) concluded that (a) the *last* unmined major reserve of strippable coal in the Midwest was now under development, (b) that no new comparable strip operations would be developed and that (c) operators "have been unable to find economically strippable reserves not now controlled by others." This report confirmed its earlier opinion that contiguous coal reserves over 10 million tons were not available in Illinois for purchase from non-operating owners. (Letter attached to DX 87, A.Ex.791.) The Government admitted that this *was* the opinion of Paul Weir Company (acknowledged by a Government witness to be one of the most widely known and highly regarded mining engineering companies in the world),[24] but, typically, the Government denied that the opinion was accurate. (GRF, p. 209.)

There was also direct testimony by executives from Amalgamated Industries (a pseudonym to protect trade secrets) and Humble Oil and Refining Company that their own search for mineable strip coal in Illinois had been unsuccessful. (Dorrance A.394; Stipulated Testimony of George H. Shipley, A.848.) In addition, two Government witnesses confirmed the unavailability of strippable reserves: Mr. Hopper of Ayrshire Collieries recognized that "it is common knowledge within the coal industry that strip reserves available for acquisition are in extremely short supply" (Hopper A.1503), and the Government's own trial econo-

[24] Hopper A.1504. The Government also admitted that Paul Weir Company had served for 31 years as mining engineers and geology consultants for the Federal Government, coal producers, railroads, electric utilities, mineral ore firms and financial institutions. GRF, p.3.

mist, James Folsom, was forced to concede that "this record indicates that high quality strip reserves are relatively scarce in Illinois." (Folsom A.1693.)

Deep Mines. The Government also quarreled with the assertions by defendants that United Electric had no experience in deep mining, no ability to develop deep coal reserves and no likelihood of acquiring deep coal mining expertise. Here again, defendants carried the day on these factual issues with a wealth of evidence from a variety of sources.

The trial court held that "United Electric is a strip mining company with no experience in deep mining nor likelihood of acquiring it." (J.S. App. 61a.) These findings were in turn supportive of the court's conclusion that United Electric was not a competitive force: neither the limited marginal deep coal reserves controlled by United Electric,[25] nor those that might be available for purchase in the Midwest, would be of any help to an independent future for the company.

The evidence sustaining these findings may be summarized as follows:

Deep Mining Experience. As observed by the 10th Circuit in the *Kennecott* case, the "essentials" for new entry into the coal business are "extensive reserves and ready ability to deliver," "experience, know-how and equipment." *Kennecott Copper Corp.* v. *Federal Trade Commission*, 467 F.2d 67, 74 (10th Cir. 1972). With respect to deep mining, United Electric has none of these.

---

[25] The evidence was that United Electric's only deep coal reserve field, Round Prairie, was not commercially mineable by *anyone* in the near future. See DPF 428-30, A.1004; Nugent A.63-65; Camicia A.77-78, 91-93; Morris A.118-19. See also Camicia A.1364-65; Hopper A.1493, 1499-1501. The Government admitted these reserves "may not be commercially mineable at the present time." GRF, p.220.

At the time of its affiliation with Freeman, United Electric had been strictly a strip mining company; it had acquired neither the equipment, personnel, nor expertise required for successful entry into deep mining.[26] The company had stated in its 1956 Annual Report that, "For thirty-eight years your Company has been engaged in a single business—mining bituminous coal by the strip or open pit method. . . ." (Kolbe Dep. Ex. 2, p.7, A.Ex.1526.) Frank Kolbe, United Electric's chief executive from 1939 to 1959, repeatedly proclaimed that "underground mining is not our business," and that to have gone into deep mining would have been "something completely new."[27] As the Government admitted, United Electric's two attempts in the 1950's to engage in drift mining[28] were short-lived and unsuccessful (GRF, p.19): one lasted two years and "failed miserably", and the other involved only the purchase of an experimental mining machine which never worked and was junked.[29]

Deep Coal Reserves. Prior to July 31, 1958, United Electric had never acquired any deep coal reserves that had not been part of strip acreage at existing mines. The deep reserves they did control at that time were all adjacent to

[28] Drift mining involves merely punching into an already exposed seam of coal, usually from the pit floor of a strip mine. See Camicia A.1358-60.

[29] Morris A.113; Tarzy A.267-68; Kolbe A.159-62; DX 1, A.Ex. 197; Kolbe Dep.Exs.55 (p.5), 57 (p.6).

their strip operations; in any event, these amounted to only 17 million tons, of which 5 million had just been acquired solely in order to obtain contiguous strip reserves.[30]

After July 31, 1958, as the evidence showed, United Electric did begin to acquire deep coal reserves in the so-called Round Prairie Field. This activity was traceable to the growing contact between Freeman (an experienced deep coal miner) and United Electric, and was built upon United Electric's then current undertaking to acquire deep coal reserves as nominee for one of its customers.[31]

The evidence further demonstrated that United Electric never gave serious consideration to any deep coal reserves until the management of Freeman and United Electric became closely associated and, in fact, since 1958, United Electric made it a practice to seek Freeman's advice regarding any deep mining possibility.[32] Finally, it was not until its 1961 Annual Report that United Electric for the first time disclosed to its stockholders that it controlled deep coal reserves. (Kolbe Dep.Ex.7, p.7, A.Ex.1532.)

Deep Mining Potential. The evidence was overwhelming that there was no reasonable probability that United Electric could successfully undertake deep mining and, therefore, no reasonable probability that it would try. This

Ex.42, A.Ex.1691; Morris Dep.Ex.46, A.Ex.1693; Morris Dep. Ex. 55, A.Ex.1695; Morris Dep.Ex.62, A.Ex.1712.

evidence consisted of the opinion of Paul Weir Company, expressed in the Report referred to above (DX 87, A.Ex. 751), the testimony of others experienced in the field, and the views of coal consumers. As the Weir report concluded,

> "While it is, of course, impossible to state for certain whether or not United Electric would even have attempted to undertake deep mining, it is improbable that they could have done so successfully, and, therefore, highly unlikely that they would have tried. This would have been true even if United Electric had had the best deep-mining reserves to work with." (DX 87, pp.29-30, A.Ex.781-82.)

As the evidence showed, United Electric's strip mining experience would be of no value to it in attempting to undertake deep mining. There is virtually no phase of the expertise acquired in strip mining than can be carried over to deep mining, and there is no correlation between the engineering and know-how related to each. (Camicia A. 1360-61.)

Strip mining is in many ways analogous to the earth moving which road contractors perform. While deep mining is very difficult and highly technical, strip mining involves none of the elements of shaft and hoist construction, underground roof conditions and maintenance, gas emission, drainage, ventilation, extrication methods, mine safety problems or equipment peculiar to deep mining. Because of these complexities, deep mining entails risks unknown to strip mining, and the failure of deep mines because of bad judgment is not infrequent.[23]

---

[23] See DPF 413-420, A.1000-02; Camicia A.1359-60; Gaunt A.588-89; Kolbe A.156-58. Precisely on point is the fact that Freeman's deep coal mine "Crown" had to be abandoned in 1971. See 1971 Annual Coal, Oil & Gas Report, Illinois Dept. of Mines and Minerals, p.18. The Crown mine had produced 1.8 million tons in 1970. See 1970 Annual Coal, Oil & Gas Report, Illinois Dept. of Mines and Minerals, p.18.

Nicholas T. Camicia, President of Pittston Company (one of the world's largest deep mining coal producers), and a past president of Freeman-United Electric, testified at trial. On the basis of his professional knowledge and expertise as a deep mining engineer and executive, and his familiarity with United Electric's capabilities and personnel gained while serving as the company's president, he did not see how United Electric could possibly make a successful entry into the deep mining of coal:

> "You can go out and pick up any kind of construction worker and start up a strip mine. But in deep mining it is a very different business, and it takes a different type of person, even insofar as attitude."[34]

It was Mr. Camicia's conclusion that United Electric "certainly was not in a position to go into a deep mine venture" and that "they would have made a mistake if they had tried." "I don't see how they could even make a start at it." (Camicia A.1365-66, 1361.)

An additional factor that would make a deep mining attempt by United Electric even more unlikely was the grave doubt that utility companies or any other large buyer of coal would be willing to enter into a contract for underground coal with a company with no experience. As one utility president testified, "we always have felt or thought of United Electric as a strip mine company, not having any prior experience with deep mining, I would say that we would be hesitant about entering any commitment for coal from an unknown source, so to speak." (Steele A.1279-

---

[34] Camicia A.1360-61. One United Electric executive put it this way: "We are afraid. If you told me . . . that starting tomorrow you can't do what you are doing, we are going to send you down to train to be the superintendent for an underground mine, I would say, 'Uh-uh, I am on my way. Just get another boy.' " Tarzy A.244.

80.) The testimony of other consumers reflected the same viewpoint.[35]

Confirmation of the above analysis resided in the observation that, with the single exception of the recent venture by the world's largest industrial corporation,[36] there was no evidence that any company had ever attempted to make a grass-roots entry into deep mine coal operations in recent history in the Midwest.[37] The Government had claimed at trial that Ayrshire Collieries had done so, and one of its executives was called by the Government as a witness. He related, however, that Ayrshire had opened a deep mine only *after* acquiring two deep mine coal companies and even then the mine had been a failure and should not have been built. (Hopper A.1495-97.) This Government witness also concluded that United Electric "would be in a very awkward position" were it to attempt underground mining. (*Id.* at 1509.)

Faced with this abundance of evidence, the Government is left in its brief with the observation that "United Electric has had both the *financial* resources and general *marketing* experience necessary to enter deep mining." (Gov't. Brief, p. 72.) But the evidence showed that these attributes were simply not enough; more is required to enter deep coal

---

[35] Moser A.1403-04; Tomey A.1114-15; Gaunt A.588-89; Abrahamson A.663; Sloane A.359-60; Morris A.119.

[36] Both common sense and the Government's own prior observations belie the validity of any parallel (Gov't. Brief, pp. 72-74) between what Humble Oil, subsidiary of Standard Oil Co. (New Jersey) would do and could do, and what an independent United Electric might successfully undertake. In their Briefs and proposed findings (DX 81-83, A.Ex.617-39) in *United States* v. *Standard Oil Co. (New Jersey)*, 253 F.Supp. 196 (D.N.J. 1966), the Government pointed out that there is no correlation between Standard Oil's ability to make a grass-roots entry into deep mining and that of a smaller company attempting a similar venture. (*Id.* at 200, 208, 223, 227.)

[37] See Nugent A.72; Camicia A.1362.

mining successfully than money and the ability to sell coal, as the record amply demonstrates.

Based upon the entire record, we respectfully submit that the District Court's resolution of the factual issues concerning United Electric's bleak and irremediable future were clearly correct.[38] The finding that United Electric was not and could not become a viable competitive force stands unshakable. This is apparent, we suggest, from the Government's confession in its Brief (page 2, note 1) that "[t]he focus has been shifted [since its Jurisdictional Statement] from the evidentiary support for the finding to its legal sufficiency as a basis for concluding that the merger would have no anticompetitive effect." The Government is reduced, in the end, to musing that it is "hard to believe" that United Electric "would idly sit by and allow its entire coal business to disappear."[39] This incorrectly states the

---

[38] Contrary to the Government's representations that these findings and the evidence in the record related solely to the time of trial (Gov't. Brief p.71), United Electric's reserve crisis was shown to have existed in the 1950's and its inability to acquire additional reserves was established by evidence relating to that period and throughout the 1960's, as well as to the time of trial. See discussion at pages 69 to 76, *infra*.

[39] Gov't. Brief. p. 73. Apparently, however, this not infrequently happens. Little Dog Coal Company, according to the Government a "leading" producer in 1967, abandoned operations the following year. Compare GX 72, A.Ex.91, with Beck Dep. Ex.1, A.Ex.1411. The Government offered no explanation as to what happened to its other "leading" producers Mid-Continent Coal Corporation, Lumaghi Coal Company, Saxon Coal Corporation, Young's Coal Corporation, Crab Orchard Cooperative Coal Company, J.W. Coal Company, Big Muddy Coal Company, Ajax Coal Company, Jo-Lor Mining Company, or Snow Hill Coal Corporation (all of which have apparently abandoned operations)—other than to show that they were not acquired by other Midwest coal producers. Compare GX 87, A.Ex.101 with GX 62-86, A.Ex.81-100, DX 46, A.Ex.295.

issue[40] and, in any event, manifestly fails to overcome the compelling force of the evidence.

4. Other Industry Forces At Work Make It Inconceivable The Combination Could Have An Adverse Effect on Competition.

In the context of United Electric's terminal condition in an industry marked with intense competition, only blind adherence to numerology can foster a belief that the Freeman-United Electric combination poses *any* threat to competition, much less the "substantial" one required by Section 7.

In reviewing the pressures it deemed "crucially relevant to its assessment of the competitive effect of the United Electric-Freeman combination," (J.S. App. 53a), the District Court found that the intense competition which Midwest coal producers face is likely to increase even more (J.S. App. 18a) in light of:

(a) competition from nuclear energy and other alternative fuels (J.S. App. 27a-41a);

(b) the growing concern with the environment which will greatly disadvantage companies, like United Electric, that produce only low quality, high sulphur coal (J.S. App. 41a-53a);

(c) pressures from large, informed and capable buyers of coal (J.S. App. 18a-27a); and

---

[40] While United Electric has no future in the Midwest, it is not going to let its coal business disappear. It has coal reserves in Oklahoma and Colorado to which it has now turned its attention as well as to other opportunities in the West; this is obviously where the company's future resides. See J.S. App.61a; Tarzy A.282-90; Tarzy Dep. 429-38; Inman A.202-03; Jensen A.291-92; DX 29, A.Ex.253; DX 31, A.Ex. 255; DX 60(a), A.Ex. 517. By agreement of the parties, United Electric's western reserves were not an issue in the litigation. See J.S. App. 9a, n.8; DX 47, ¶42, A.Ex.339; A.1135-36.

(d) the presence of a substantial number of viable coal producers, many with multifuel capability. (J.S. App. 16a-18a.)

Given these industry forces at work, United Electric, with only 4 million tons of unsold coal, just cannot affect the level of competition in its markets, one way or the other.

Interfuel Competition. Based upon Government reports and studies,[41] the statements of Government officials,[42] energy experts,[43] trade association executives,[44] and a wealth of other evidence,[45] the trial court fairly concluded that:

> "Interfuel competition will continue to erode coal's share of the energy market as more and more industrial consumers convert from coal to gas or oil, and as these fuels, along with nuclear energy and the emerging technology of still other alternative power generation sources, further challenge coal's share of the fuel needs of electric utilities." (J.S. App. 28a.)

While its Brief to this Court quibbles with the intensity of interfuel competition in the Midwest, the Government concedes "[t]here may well be an energy market" (page 20) and time and again acknowledges the effects of interfuel

[45] See, generally, DPF 192-282 (A.938-63) and the evidence referred to therein.

competition.[46] In view of the evidence in the record, recognition that coal has in the past, does in the present, and will in the future face intense competition from suppliers of alternate fuels is inescapable. The trial court's detailed and reasoned description of this battle (J.S. App. 27a-41a) well summarizes the evidence and needs not to be repeated here. Suffice it to say that the Government's own trial economist testified that "the customers in this case all—all the utility customers have indicated that they consider all sources of fuel in making the decision. . . . They did not say that they considered the primary competition coal with reference to future facilities, certainly." (Folsom A.1703.)

Victor Wood, Superintendent of Fuel Procurement for Northern States Power, articulated the realities of the situation:

> "Certainly competition between coal suppliers is a big factor, but I believe overriding this, which sets the over-all competitive picture, is the alternate fuel competition. There is competition among all fuels as well as among coal suppliers." (Wood A.1188).

This was similar to the views of Gordon Corey, Chairman of the Finance Committee of Commonwealth Edison:

> "Q. In your opinion, Mr. Corey, what is Commonwealth Edison's major concern with respect to competition among its fuel or energy suppliers?
>
> "A. I guess it is to have adequate competition and as the energy field gets more diverse, it is hopefully to continue to have effective competition between coal and oil and nuclear. I believe that is one way of putting it." (Corey A.1420.)

It was accordingly concluded by the trial court, supported by the views of defendant's economist Dr. Peter O. Steiner,[47]

---

[46] Gov't. Brief, pp. 3-4, 14-15, 22, 24-28.

[47] For Dr. Steiner's qualifications, see DPF 42, A.897-98.

that this intense level of interfuel competition was necessary to any valid predictions concerning the coal industry's future: "Because interfuel competition particularly provides utilities with a strong bargaining weapon in negotiations with coal producers, this competition exerts strong pressure on the market in which coal producers sell their form of energy."[48]

The role of this factor in predicting the future effect of the Freeman-United Electric combination on competition is clear: the level of that competition is so significantly influenced by the rivalry among various forms of energy that it belies common sense to contend that a competitively moribund coal producer like United Electric even enters the picture.

Concern With The Environment. The court found, on the basis of the substantial evidence in the record concerning environmental controls,[49] that "[t]he air pollution restrictions adopted throughout the midwest are substantially increasing the already intense competition which coal faces from other fuels." (J.S. App. 43a.) Moreover, the court observed, electric utilities and other large coal consumers will not be able to avoid air pollution restrictions by locating future facilities in rural areas in view of the demand for state-wide controls.[50] Even when commercially acceptable pollution control devices become available,[51] the capital and operating

costs involved may well lead to the exclusion of coal from the competitive picture for some utilities in favor of other fuels.[52] (J.S. App. 41a-51a.) Finally, many of the governmental restrictions adopted to date have taken the form of banning the burning of high-sulphur coal altogether.[53] This has been particularly grievous in the case of producers, such as United Electric, who produce only high-sulphur coal. (J.S. App. 52a.)[53a] As one utility executive put it, "Air pollution is getting to be the overriding issue."[54]

The essential point here is that environmental controls will handicap coal producers in their ability to compete. Illustratively, United Electric's largest former customer—Commonwealth Edison—testified at trial that "we have sort of put our eggs in the nuclear basket" and that the move toward nuclear power "is the best way to take care of our massive electric power generation problems with a minimum of disturbance to the environment." (Corey A. 1414.) Moreover, because of its low-sulphur coal program, Edison has begun "phasing out" its high sulphur coal producers. "As you know," Finance Committee Chairman Corey testified, "the United Electric contract expires this year and has not been renewed." (*Id.* at 1437-38.)

[53a] The trial court found in this regard that, because of air pollution regulations, United Electric "will not be able to serve [the Chicago area] market." (J.S. App.62a; see also J.S. App.58a.)

[54] Tomey A.1130. See, generally, DPF 246-282, A.952-63. See also Steele A.1267-68; Wood A.1175-76, 1190-91; Davis A.1199-1200, 1207-08; Moser A.1389-91; Corey A.1414-16; Hill A.1313; Gamble A.1350-51; Schotters A.642-43; Petersen A.368-71; Morrison A.607-08; Ward A.560; Redard A.570-71; DX 71, A.Ex.591; DX 176, A.Ex.1158; DX 178, A.Ex.1160; DX 179, A.Ex.1161; DX 187-88, A.Ex.1169-70; DX 191-92, A.Ex.1173-74; DX 234 (pp.6-7), A.Ex. 1266-67; DX 238, A.Ex.1278; DX 239, A.Ex.1279.

Customers. The court found that mergers within the utility industry had both diminished the number of utility companies and had increased the purchasing power of those surviving. In light of the fact that fuel expenditures were a major component of a utility's operating cost, it was also found, and admitted by the Government, that utilities regarded fuel purchasing as a major executive responsibility, exercised with great sophistication and knowledge. (J.S. App. 24a-26a; GRF, p.54; DPF 187, A.936-37.) Witness to this bargaining power was the testimony of executives of all the significant coal users in the Midwest, including Commonwealth Edison, the Tennessee Valley Authority, and 12 other utility customers of Freeman or United Electric.[55] These fourteen firms consumed about 70 million tons of coal in 1967, an amount 10 percent greater than the *entire* Illinois production of coal that year, 3½ times greater than that of the state's largest producer, and more than one half of all the coal produced in Illinois, Indiana and west Kentucky.[56]

The evidence from these witnesses recited the great care with which coal contracts were negotiated,[57] the playing of

[55] Central Illinois Public Service ("CIPS"), Dairyland Power Cooperative, Illinois Power Company, Electric Energy, Inc., Union Electric Company, Wisconsin Electric Power Company, Wisconsin Public Service Company, Wisconsin Power and Light Company, Central Illinois Light Company ("CILCO"), Interstate Power Company, Iowa Public Service Company and Northern States Power Company.

[56] Compare DX 85, Table XXX, A.Ex.717, with GX 72 and 85, A.Ex.91, 98. Consumption totals for Interstate Power Co. and Iowa Public Service Co. were taken from Kurtz Dep. Ex.8, pp.17, 19.

[57] See, generally, DPF 167-191, A.931-38. Gamble A.1329-30, 1343-46; Hill A.1290-91, 1309; Steele A.1263-64; Davis A.1196-97; Moser A.1385; Corey A.1404-05; Tomey A.1105-06; Wood A.1173; Ward A.547-48; Nicosin A.498-99; Redard A.569; Gaunt A.576-77, 592; Morrison A.596-97; Abrahamson A.650-51; Schotters A.636-37, 642-43; DX 150, p.51, A.Ex.1108.

one coal supplier against another,[58] the use of inter-fuel substitutability as leverage,[59] and the future likelihood of pooling of purchasing power.[60] In sum, there was no denying the fact that utilities wielded great economic power. (See, particularly, Gamble A.1343-44.) As the court noted, "the Government has conceded that utilities have at least equal bargaining power with coal producers in the midwest." (J.S. App. 27a.) The dimensions of that power were reflected in the Government's haste to point out that Commonwealth Edison, for example, did not take "unfair advantage" of midwestern coal producers. (Government's Proposed Findings of Fact, p.25.)

Producers. From the evidence, the court noted the presence in the market of a substantial number of viable coal producers, and that United Electric had found itself competing with much larger corporate enterprises which produced and sold a variety of energy sources and could thus fill all of a utility's fuel needs. (J.S. App. 18a, 40a.)

Treating Freeman-United Electric as one, the Government identified ten "leading"[61] coal producers in Illinois and the Midwest in 1967, producing a total of 63.6 and 118.3 million tons respectively. (GX 72, 85, A.Ex.91, 98.) The Government's 1967 lists, however, failed to include the names of two new entrants to Illinois and the Midwest: Humble Oil and Refining, which was constructing a deep

---

[58] Davis A.1219-20, 1225. This was admitted by the Government. GRF, p.54; DPF 188, A.937-38.

[59] Nicosin A.534; Schotters A.641.

[60] DX 232, A.Ex.1247; DX 233, A.Ex.1249; DX 257 (§ IV and Apps. A, B and C), A.Ex.1398-1405.

[61] Companies producing annually more than 300,000 tons in Illinois or more than 1,000,000 tons in the Midwest were defined by the Government as "leading" producers. See note 1 to both GX 72 and GX 85, A.Ex.91, 99.

mine in Illinois capable of producing 3 million tons a year and the 6 million ton operation being divested by Peabody.[62]

Further, it was shown that all of these "leading companies," save one, had substantially greater coal reserves than United Electric, without regard to mineability. In any event, total coal reserves held by all companies surveyed in the Midwest totalled in the billions of tons. (DX 62, A.Ex. 578.)

It was also found that the oil industry had established itself as a major element in coal production, linking under common ownership in many instances the energy resources of coal, oil, gas, uranium, oil shale and tar sands. In fact, oil companies accounted for more than 25 per cent of the coal produced in Illinois, Indiana and western Kentucky in 1967. (J.S. App. 40a.) Significantly, Freeman and United Electric had no affiliates engaged in any other fuel industry. (J.S. App. 3a-4a; GX 138.)

In light of this evidence, it is clear that the level of competition produced by the large number of viable coal producers moves without regard to United Electric's liquidating position, and United Electric is powerless to affect it.

B. The Combination of Freeman-United Electric Did Not Eliminate Actual or Potential Competition.

With respect to the Government's attempt to prove that the combination eliminated competition, the District Court observed that "[c]rucial to the Government's case is proof that United Electric and Freeman are actual or potential competitors." (J.S. App. 61a.) The court settled this factual issue against the Government.

---

[62] See Stipulated testimony of George H. Shipley (A.848), DX 84, A.Ex.640, and page 16, *supra*.

The Government relied at trial, as it does here (Gov't. Brief, pp. 11, 60-62), on a series of charts purporting to show that in 1965 through 1967, Freeman and United Electric sold coal to the same customers. (GX 88-91, A.Ex.107-17.) In rebutting this claim, defendants introduced uncontradicted documents and testimony, much of it from the very customers involved.[63] This evidence was to the effect that, with the possible exception of sales to Commonwealth Edison, none of the shipments chosen by the Government for analysis would have been competitive had Freeman and United Electric been independent. The Government's charts were totally discredited by the following evidence:

1. Shipments to four of the Government's "common customers"—Central Illinois Light Company, Illinois Power Company, Caterpillar Tractor Company and Marquette Cement Manufacturing Company—involved entirely different plants; no one facility was able to be served competitively by both Freeman and United Electric.[64] This was established by the testimony of defendants' executives and directly confirmed by the customers involved.[65] The explanation of the Chairman of the Board of Illinois Power Company is illustrative: "Because of the location of the United Electric and Freeman mines as related to the generating stations of Illinois Power Company we had not regarded the two companies as competitors with respect to

---

[63] See, generally, DPF 346-60, A.980-85.

[64] During the first part of 1965, United Electric was serving the Vermillion plant of Illinois Power Company with coal from its Mary Moore mine, 15 miles away. The mine closed earlier than anticipated, and upon the insistence of Illinois Power, Freeman shipped coal to the plant at a sacrifice in order to fulfill United Electric's contractual obligation. Once the contract ran out, Freeman ceased shipments. (Morris A.1077-78; GX 90, A.Ex.114.)

[65] Morris A.1072-74, 1077-79; Nugent A.1517-19; Davis A.1199-1200, 1204-05; DX 76, A.Ex.604; DX 230, A.Ex.1244.

service to any particular station. Freight costs prevented such competition." (DX 230, A.Ex.1244.)

2. Freeman's shipments to four other of the Government's "common customers,"—Dairyland Power Cooperative, Foote Minerals, Union Electric Company and the Meredosia Station of Central Illinois Public Service Company—were a by-product dust, which United Electric did not and could not produce; United Electric's shipments were screenings, a product not competitive with dust. Again, the testimony of defendant's executives that these shipments were non-competitive was directly confirmed by the customers involved.[88]

3. Similarly, different products were shipped by both companies to another of the Government's "common customers," Inland Steel Company. United Electric's shipments were steam coal for the generation of electricity, while Freeman shipments were metallurgical coal for making steel. (Morris A. 1078-79.) The Government has conceded that United Electric cannot compete with Freeman for the sale of metallurgical coal. (GRF, p. 8; DX 46, p. 35, A.Ex. 329.)

4. The two remaining "common customers", as shown through the testimony of the customers involved, were found to be situations where United Electric had no competitive status at all. In the case of the Tennessee Valley Authority, permission had been received to ship coal from United Electric's Fidelity mine in fulfillment of Freeman's contract with TVA during certain periods of the year when adverse river conditions closed the Fidelity mine from its natural markets. United Electric alone could not have com-

[88] See, generally, DPF 351-54, A.981-82; Morris A.1074-77; Morris A.120-21; Nugent A.1518-19; Tarzy A.258-62; Moser A.1388; Tomey A.1109-11; DX 231, A.Ex.1245.

mitted itself to TVA competitively on a long-term or even yearly basis. As the former coal purchaser for TVA explained at trial: ". . . [I]t is highly unlikely that they [United Electric] would have or could have competed with the other sources of coal . . . ."[67] Mr. Folsom, the Government's own economist, was equally straight-forward:

> "The way the thing occurred in the record, I would not say that that particular shipment represented competition." (Folsom A.1694-95.)

It was also revealed that United Electric could not sell directly to Wisconsin Public Service Company because the characteristics of its coal did not fit the design of the utility's boiler equipment. United Electric shipments were undertaken solely because Freeman had trouble fulfilling its contractual obligations in 1965 and 1966 (the only years in question), and only because the coal could be mixed with Freeman coal at a dock in Chicago in order to meet the coal specification requirements. (Morris A.1075-76; Nugent A.1518-19.) Again, it was confirmed by the Superintendent of Steam Plants for Wisconsin Public Service Company that, independently, United Electric would not be considered by his company as a potential supplier. (Morrison A.604.)

It thus remained that only one of the Government's "common customers" involved a situation where coal shipments by the two companies might have been competitive: sales to Commonwealth Edison Company. Even here, however, these sales had to be considered in light of Edison's coal requirements. Because Edison was required to purchase coal from several Freight Rate Districts in order to fulfill its needs, as the Government admitted, the competition which a given mine had to meet in bidding for Edison

[67] Hill A.1298-99. See also Hill A.1297-98; Morris A.1075; Nugent A.1518-19; Nugent A.41-42; Folsom A.1694-95; Tarry A.232-34; DX 103-04, A.Ex. 996-98.

business was that of the other mines within its Freight Rate District, rather than that of mines in other districts. (GRF, p.180; Nugent A.45-46; Tarzy A.264-66; Camicia A.85-86.)

Regardless of whether United Electric could have competed with Freeman for the business of Commonwealth Edison, it cannot be concluded that the United Electric-Freeman combination had any adverse effect on that company, as the testimony of one of Edison's top officials made clear. (Corey A.1419-21.) Edison's $2.5 billion in assets, the magnitude of its coal purchases, its commitment to nuclear energy, its readiness to use alternative fuels and its ownership of its own coal reserves and uranium resources made it totally improbable that Edison could have been adversely affected by the combination.[68]

The weight of the foregoing evidence is hardly overcome by the assertion in the Government's Brief (page 60) that United Electric and Freeman solicited the same customers. Since coal purchases are made for specific plants, rather than on a company-wide basis, solicitation of the same customers by the two companies means nothing in and of itself.[69] Nor do the testimony and exhibits referred to on the same page of the Government's Brief compel a contrary conclusion.

---

[68] See Corey A.1405-09, 1414, 1420, 1446-47; DX 90, A.Ex.866; 93-100, A.Ex.889-912; GX 135, A.Ex.126. The Government admitted that 1967 sales to Commonwealth Edison accounted for about a third of United Electric's production. Edison purchases from United Electric, on the other hand, represented scarcely a tenth of its overall coal requirements. See DPF 359 (note), A.984.

[69] The same was found to be true in *United States* v. *Crocker-Anglo Nat'l. Bank*, 277 F. Supp. 133 (N.D. Cal. 1967), where the court noted that "the fact that each of the banks had the same customers did not indicate that they were competing for the business of that customer." 277 F. Supp. at 177.

The cited testimony of Mr. Camicia (Camicia A.83-84) reflects nothing more than the data shown on the Government charts discredited at trial, and Camicia testified he knew of no other "common customers." (Camicia A.79-83.) Mr. Kolbe's testimony referred to by the Government was very general and imprecise; its implications were contradicted by John Morris, Vice President in charge of sales for United Electric and, subsequently, President. Kolbe testified Mr. Morris was far more informed than he about the marketing of coal. (Kolbe A.131-32.) Significantly, Morris testified that the "common" shipments of United Electric and Freeman could not have been competitive. (Morris A.1069-81.) Government Exhibits 93 and 94, A.Ex.118, 121 (letters from Central Illinois Public Service and Illinois Power Company) show only that Freeman and United Electric both sold coal to both companies, as explained above. Neither supports the Government's proposition, as the subsequent letters from these customers make clear. (DX 230 and DX 231, A.Ex.1244-45.) Finally, the cited testimony of Edison's Gordon Corey (A.1437) referred to the period prior to 1959 and, in any event, must be viewed in the context of Edison's bargaining position and Mr. Corey's testimony that the combination had had no adverse effect on Commonwealth Edison since that time. (Corey A.1419-20.)

The Government cites no other evidence to support its contention that there existed competition between Freeman and United Electric which had been eliminated, and there is none in this immense record. In view of all the evidence, the court was clearly correct in finding that "an independent United Electric would not and could not compete with Freeman to any substantial degree." (J.S. App. 61a.)

C. Evidence From Numerous Knowledgeable Industry Representatives Confirmed That The Freeman-United Electric Combination Has Not Led And Is Not Likely To Lead To a Substantial Lessening Of Competition.

Given the fact that the Freeman-United Electric combination was a decade old when the complaint herein was filed, the Government devoted extensive discovery efforts to the securing of opinions from both coal producers and consumers as to the effect of the combination upon them.[70] Such opinions were uniformly adverse to the Government, as was revealed in answers to interrogatories, in the depositions, and at trial.[71]

The Government admitted in its answers to defendants' interrogatories that it had "no information" as to any competitor who had been or would be "adversely affected or disadvantaged in its ability to compete" or any customer who had been or would be "deprived of actual" or "potential competition" by reason of the combination. (DX 46, pp. 8, 11, A.Ex.302-03, 305.) To the contrary, the Government interrogatory answers identified three companies which had declared that they had not and would not be adversely affected. Significantly, the only coal producer called as a witness by the Government was highly critical of the Government's efforts and objectives in the litigation. (Hopper A.1507-09.)

---

[70] See, *e.g.*, DX 46 (pp.8-9), A.Ex.302-03; DX 66, A.Ex.580; DX 73, A.Ex.599; DX 77, A.Ex.607; GX 101.

[71] See, generally, DPF 431-441, A.1005-09. This is analogous to what transpired in *United States* v. *Tidewater Marine Service, Inc.*, 284 F.Supp. 324, 340 (E.D. La. 1968): "[O]ne of the questions on the interview form used for the survey conducted by the government was whether the merger would affect the business of the firm interviewed; yet the Government was unable to introduce even one statement from a competitor indicating that the merger would have an adverse effect on his business."

The Government also admitted there was testimony in the record concerning the competitive implications of the combination from large, medium size and small public utilities, a rural electric cooperative, a federal electric authority, a retail coal dealer and several industrial concerns. (GRF, p. 225). This testimony from a broad cross-section of consumers and subjected to Government cross-examination was, without exception, supportive of the proof that the long-standing affiliation of Freeman-United Electric had not had, and was not likely to have, any adverse effect on competition.

This evidence was properly considered by the District Court. As the Government has stated in other cases, the testimony of industry experts about the actual competitive situation in the industry "is an invaluable and time honored mode of evidence in antitrust cases where the effect on competition is an issue." See *United States* v. *Pabst Brewing Co.*, 233 F. Supp. 475, 478-79 (E.D. Wis. 1964), quoting the Government's trial brief in that case.

We are mindful of this Court's admonition in *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 367 (1963), that industry testimony is entitled to little weight if the witnesses fail "to give concrete reasons for their conclusions." Accordingly, it is important to demonstrate that each of these witnesses in *this case* was able to do so.

Before expressing their conclusions as to the effect upon them of the Freeman-United Electric combination, the producer and consumer witnesses testified at length concerning the factors that governed their opinions. These included the role in the marketplace played by vigorous interfuel competition;[73] the impact on coal consumption of

[73] Wood A.1188; Steele A.1265-68; Gamble A.1344-47; Davis A. 1199-1200, 1202-03; Moser A.1389-90, 1402-03; Corey A.1406-07;

the increasing concern with air pollution;[73] the important role played by transportation factors and coal quality characteristics in determining the markets that mines in any Freight Rate District are able to serve;[74] United Electric's lack of coal reserves necessary to compete for future long term utility contracts;[75] and the fact that United Electric and Freeman had long been predominantly complementary rather than competitive companies.[76]

The Government's lone attempt to establish that these industry witnesses were indifferent to, and unsophisticated about, the competitive implications of mergers of coal producers, occurred during the cross-examination of A. H. Davis, President of Central Illinois Light Company. This elicited the fact that Mr. Davis had, in the past, taken the initiative in complaining to the Department of Justice when his evaluation led him to conclude that another merger between two coal producers *did* pose a threat to competition:

> "Q. Would you be concerned, Mr. Davis, as President of CILCO, if UEC and Freeman merged with Truax-Traer?
>
> "A. As your Department undoubtedly knows, we made a complaint several years ago about the merger of two coal companies in our area, and you have reached a satisfactory settlement, I take it, with those two companies, so anything that we feel reduces the amount of competition in our area, we are certainly not that bashful about making a complaint. If Truax-Traer were to merge with, say, Peabody in our area, we'd make another complaint.
>
> "Q. Why would that bother you, Mr. Davis?
>
> "A. It's a reduction of competition in our area." (Davis A.1222-23.)

In view of the virtual census in the record, of the very consumers on whose behalf this action was purportedly brought, regarding the effect of the Freeman-United Electric combination upon them, the trial court properly concluded that "evidence from numerous knowledgeable industry representatives, including competitors and customers of United Electric and Freeman, *confirms* the defendants' contention that the challenged combination has not led, and is not likely to lead to a substantial lessening of competition." (J.S. App. 65a.)

D. There Remains No Other Justification For the Government's Complaint.

The Government has failed to explain why it waited until 1967 to challenge an affiliation that had its inception, and was disclosed, in 1954; nor has it explained why the Antitrust Division upon receiving specific information concerning the combination in 1960 expressed no concern and took no action.[77] In the interim, no customer or competitor has come forward to support the Government's case, and a distinguished trial judge after an extensive trial has rejected it. Freeman-United Electric has been a fact of record since 1959, and the Government has failed to show in what fashion the substantial threat to competition they claim to see has become "evident." Far from threatening "to ripen into a prohibited effect," *United States* v. *duPont & Co.*, 353 U.S. 586, 597 (1957), this longstanding affiliation never has, does not now, and never can threaten competition. We suggest, therefore, that defendants should be permitted to go their way. See *United States* v. *U. S. Steel Corp.*, 251 U.S. 417, 452-53 (1920); *United States* v. *Kryptok Co.*, 11 F.2d 874, 875 (S.D.N.Y. 1925); *United States* v. *Inter-Island Steam Nav. Co.*, 87 F.Supp. 1010, 1023 (D. Haw. 1950).

The Freeman-United Electric combination is totally unlike any of the acquisitions successfully attacked by the Government years after consummation. Thus, in *duPont, supra*, the course of events during the years between the stock acquisitions and the filing of the complaint had served to *increase* the likelihood of an adverse effect on competition.[78] With Freeman-United Electric, however, the increasing interfuel competition, heightened environmental con-

[77] J.S. App. 8a. The details of this investigation are set forth in DPF 132-33, A.921-22.

[78] During this time, General Motors had increased in size and duPont's sales to GM had grown substantially, as had the "potency" of duPont's stock interest. 353 U.S. at 599, 607 n. 36.

cerns, growth of utilities, and the like, during the intervening years have made it all the clearer that the combination can have no such effect.

Similarly, in *Citizen Publishing Co.* v. *United States*, 394 U.S. 131 (1969), the two companies were in sound condition at the time of trial and their separation would restore competition where there had been none for many years. Conversely, *here* the court specifically found that in view of United Electric's inability to be a competitive factor in the future, divestiture would not benefit competition. (J.S. App. 66a.)

Apart from the Government's futile claim that United Electric and Freeman could be competitors, and the easily rebutted conclusion it would force from the structural data presented (discussed below), the Government's Brief in this Court cites no other support for its claim that the Freeman-United Electric combination has resulted in any lessening of competition during the many years of its existence.

In their post-trial papers, the Government did request a finding that the combination was likely to cause the coal industry to be less responsive to changes in consumer demands. (GPF, p. 46.) However, this finding was rejected by the trial court on the basis of ample evidence. As the court found, "the past performance of the industry suggests that there has been intensive competition among coal producers." (J.S. App. 18a.)[79] In fact, the Government conceded that it "has never asserted that during the 20 years preceding 1967, the coal industry was noncompetitive," and it also admitted that the price of coal at the mine mouth as of 1968 was actually less than it was at the begin-

[79] See, generally, DPF 138-166, A.923-30; Steiner A.792, 1582-84; Steiner Dep. Ex.2, ¶3, A.Ex.1829-30.

ning of the postwar period. (GRF, pp.39-40.) The Government also acknowledged that there had been marked improvements in coal technology and techniques, that there had been a relatively constant increase in productivity from 1947 to 1967, and that during that period the f.o.b. mine price of coal had remained relatively stable despite general inflation in wholesale prices. *Ibid.*

Given these admissions and the evidence in the record, the court was virtually compelled to conclude, as it did, that the case was "devoid of any signs of anticompetitive performance." (J.S. App. 18a.)

II.

THE DISTRICT COURT COMMITTED NO ERROR IN DECLINING TO DECIDE THE CASE SOLELY UPON THE STRUCTURAL DATA SUBMITTED BY THE GOVERNMENT.

In the absence of any ground for challenging the documented *factual* findings of the trial court, the Government struggles to find a *legal* issue in regard to the subsidiary questions of market definition, asserting error in the refusal of the District Court to dispose of the case solely on the basis of the Government's structural data. The failure of the Government's case, however, was that it could not show an adverse competitive effect in *any* line of commerce in *any* section of the country—the trial court specifically holding in this regard that there would be no Section 7 violation "even were this court to accept the Government's unrealistic product and geographic market definitions." (J.S. App. 66a; see also J.S. App. 59a-60a.) Thus, the outcome below would have been no different had the market definition questions been resolved in the way the Government wished. In any event, the District Court properly analyzed the markets in-

volved and properly rejected the Government's structural data as controlling of the outcome of the case.

A. The Decision Below Did Not Turn On The Subsidiary Questions of Market Definition.

As is clear from its opinion, the District Court's resolution of the subsidiary questions of market definition were not controlling of the ultimate issues in this case. Therefore, the questions raised by the Government concerning the court's choice of product and geographic markets are not material.

This Court has made it clear that in an action under Section 7, an "examination of the particular market—its structure, history and probable future" is necessary to "provide the appropriate setting for judging the probable anti-competitive effect of the merger." *Brown Shoe Co.* v. *United States,* 370 U.S. 294, 322 n. 38 (1962). It was on the basis of precisely such an examination, involving a careful assessment of *"all* of the evidence" (J.S. App. 2a, 18a, 53a, 64a, 66a), that the District Court concluded that the challenged combination did not offend Section 7.

Significantly, not one of the many factors considered by the court in reaching its decision hinged upon resolution of the questions of market definition. These questions were thus in no sense critical to the outcome, and the court specifically held that the United Electric-Freeman affiliation would not violate Section 7 "even were this court to accept the Government's unrealistic product and geographic market definitions." (J.S. App. 66a; see also J.S. App. 59a-60a.) In so holding, the court acknowledged (J.S. App. 60a) this Court's teaching in *Pabst* that questions of market definition are "entirely subsidiary to the *crucial question* in this and every § 7 case which is whether a merger may

substantially lessen competition. . . ." *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, 549-50 (1966).

It is important to recognize that the District Court did not use the relevant product and geographic markets which it adopted as the key to the denominator for a simplistic mathematical test. To the contrary, it rejected a mechanistic approach and focused instead on the "crucial question" of the combination's competitive effects.

Accordingly, the trial court's choice of energy rather than coal as the appropriate *product* market *was not* the predicate for a finding that the challenged combination supplied an insubstantial share of energy resources consumed in the Midwest. It was designed instead to make it clear that the court had given full recognition to the intense competitive pressures from alternative fuels which, the court concluded on the basis of substantial evidence (see J.S. App. 27a-53a), were "crucially relevant to its assessment of the competitive effect of the United Electric-Freeman combination." (J.S. App. 53a.)

Neither was the District Court's *geographic* market definition a prelude to an exculpating finding of permissible market share. Rather, it was intended to facilitate an identification of areas or customers to scrutinize for the alleged anticompetitive effect (J.S. App. 57a), and to facilitate an understanding of why the Government's market share statistics were not a reliable guide to determining the level of competition in the industry. (J.S. App. 57a-60a; 62a; 65a-66a.)

Thus, as the Government itself recognizes (Gov't. Brief, p. 33 n. 21), the court's product and geographic markets were chosen not to foreclose examination of the *coal* industry in the *Midwest*, but rather because they helped to "explain a great deal of what has happened in the *coal* industry and to

its markets." (J.S. App. 52a-53a; see also J.S. App. 57a-59a.) Conversely, what the Government would have is a market definition operating as an exclusionary rule of evidence. They would ask the trial court to blind itself to factors outside the coal industry that very definitely affect the level of competition within it; and they would seek protection of their market share statistics from analysis that might show them to be misleading or meaningless.[80]

In any event, whether it is technically correct to designate the relevant product market energy or coal, there can be no escaping the hard facts of record with respect to the "crucially relevant" pressures on coal producers such as United Electric-Freeman arising from the vigorous interfuel competition existing in the marketplace, the bargaining power that such competition gives consumers, and the impact of environmental controls on coal's rivalry with other fuels.

The same is true of the geographic markets adopted by the court: whether United Electric and Freeman are said to serve different areas within a market or different markets, "viewed in the context of all the evidence in this case . . . an independent United Electric would not and could not compete with Freeman to any substantial degree." (J.S. App. 61a.) This finds parallel in *United States* v. *Crocker-Anglo Nat'l Bank*, 277 F.Supp. 133 (N.D. Cal. 1967) where

[80] The approach followed by the court below finds parallel in *Kennecott Copper Corp.* v. *FTC*, 467 F.2d 67, 71 (10th Cir. 1972) ("it seems reasonable to consider . . . the competition that exists between coal and other fuels"); *United States* v. *Connecticut Nat'l Bank*, 5 Trade Reg. Rep. (1973 Trade Cas.) ¶74,577 at 94,546 (D. Conn. 1973) ("influences of the New York banks require serious consideration and analysis when the Court considers the remaining crucial issues in the case, i.e., the impact of the merger on competition"); and *United States* v. *First Nat'l Bank of Md.*, 310 F.Supp. 157, 168 (D. Md. 1970) ("non-commercial bank activities can be taken into account in connection with the effect of the merger upon commercial banking as the line of commerce in the given market").

the court rejected the contention that there was a statewide banking market but found that, even if there were, there was no Section 7 violation in light of the insubstantial competitive overlap between the merging companies. 277 F.Supp. at 169-73, 177-78.

The court's own discussion of the likely competitive effects of the combination (J.S. App. 60a-64a) makes clear that *none* of its findings with respect to concentration, competitive overlap, types of mining, types of coal, Commonwealth Edison, United Electric's inability to serve Chicago, United Electric's "singularly unpromising" coal reserve prospects and the like were dependent upon the market definitions chosen by the court or would have been different had the markets urged by the Government been adopted.[81]

In light of the economic and commercial realities found to exist by the trial court on the basis of substantial evidence, it is clear that the decision below would have been no different had the subsidiary technicalities of market definition been resolved according to the Government's wishes. The assertions by the Government that the Court's opinion "reflects no analysis of the structure of the coal submarket or of the impact upon it of the Freeman-United Electric combination" and "no discussion of the effect of the combination on competition within the sections of the country proposed by the Government" (Gov't. Brief, pp. 32 n.20, 50 n.36) are flatly wrong. The entire opinion constitutes precisely such an "analysis" and "discussion." Accordingly,

---

[81] In *Brown Shoe*, *supra*, this Court declined to consider whether the District Court had been correct in rejecting certain proposed market definitions where such markets, even if proper, would not "aid us in analyzing the effects of this merger" and where the appellant could "point to no advantage it would enjoy" even if the markets in question were used in lieu of those employed by the district court. 370 U.S. at 327.

while defendants submit that the court's rulings on market definition were correct, it is clear that even if the markets had been defined as the Government asked, the outcome would have been the same.

B. The District Court Correctly Rejected The Market Definitions Urged By The Government.

The Product Market. There was nothing either factually or legally novel in the District Court's examination of the likely competitive effects of the United Electric-Freeman merger within the framework of an energy market. Indeed, the Federal Trade Commission recently sent to Congress a report by its Bureau of Economics on interfuel substitutability (focusing largely on utility consumers) which finds that the results of its study support the conclusion that "an energy market exists." FEDERAL TRADE COMMISSION STAFF REPORT, INTERFUEL SUBTITUTABILITY IN THE ELECTRIC UTILITY SECTOR OF THE U.S. ECONOMY 115 (1972). The purpose of the report was to analyze the extent of interfuel substitution "in order to establish the product boundaries between the various energy sources." *Id.* at 2. In doing so, it confirmed that coal, gas and nuclear energy trade in a "single market," and that "the primary fuels are generally good substitutes for one another." *Id.* at 115-16.

In his dissenting opinion in the Court of Appeals stage in the *Tampa Electric* litigation, Judge Weick was similarly persuaded that:

> "there exists such a degree of cross-elasticity between coal and other boiler fuels as to constitute boiler fuels the relevant line of commerce in this case. Each of the boiler fuels—coal, oil, gas and atomic energy—is utilized in the same manner to produce the same result.

> As each is consumed power is produced to drive the generators which in turn produce electric energy."[82]

Numerous other cases have recognized the reality of interfuel competition. See, *e.g.*, *Federal Power Commission* v. *Hope Natural Gas Co.*, 320 U.S. 591 (1944); *Fuels Research Council, Inc.* v. *Federal Power Commission*, 374 F. 2d 842, 845, 850, 852-54 (7th Cir. 1967); *National Coal Association* v. *Federal Power Commission*, 247 F.2d 86 (D.C. Cir. 1957); *Mississippi River Transmission Corp. and United Gas Pipe Line Co.*, 41 FPC 555 (1969); *Natural Gas Pipeline Co. of America* v. *New York Central RR. Co.*, 323 ICC 75 (1964); and *Natural Gas Pipeline Co. of America*, 28 FPC 731 (1962).

Similarly, in this case, the District Court determined the "competitive battle waged by various forms of energy" to have been "documented in this litigation." (J.S. App. 55a.) Coal was found to have the same uses as the alternative fuels with which it competes (J.S. App. 27a), the same customers (J.S. App. 29a-40a), a high degree of sensitivity to price changes of other fuels (J.S. App. 13a, 28a-29a, 36a-39a, 43a-44a, 51a-52a), and was viewed as an integral part of the energy market by the public, industry, and Government itself. (J.S. App. 13a-14a, 29a, 31a-32a.)

To combat these commercial realities, the Government catalogues the differences between coal and other forms of energy. (Gov't. Brief, pp. 21-31.) To be sure, there are coal trade associations, labor unions, and publications; admittedly, coal looks different from gas, oil and uranium and is mined and prepared in a different way. But the fact that an

---

[82] *Tampa Electric Co.* v. *Nashville Coal Co.*, 276 F.2d 766, 780 (6th Cir. 1960), *rev'd*, 365 U.S. 320 (1961). In its reversal of the majority opinion, this Court found it unnecessary to decide whether boiler fuels, rather than coal alone, was the appropriate line of commerce. 365 U.S. at 328-30. But see *Brown Shoe Co.* v. *United States*, 379 U.S. 294, 330 (1962).

oil derrick is of no use in a coal mine, or that coal is black and uranium yellow, are all distinctions without a difference and contribute nothing to the determination of whether there is interfuel competition.[83] And the statement that "[c]oal's dominance . . . is not likely to disappear soon" (Gov't. Brief, p. 27) means nothing more than that the competitive battle among various forms of energy is not yet over.

While the Government's Brief adopts an essentially mechanical approach to the considerations suggested in *Brown Shoe*[84] for determining submarkets, the cases make clear that in determining the appropriate line of commerce, legalisms are no substitute for examination of the economic and commercial realities involved. The opinion in *Brown Shoe* itself notes that "Congress prescribed a pragmatic, factual approach to the definition of the relevant market and not a formal legalistic one." 370 U.S. at 336. This Court has also pointed out with reference to *Brown Shoe* that:

> "Concededly, these guidelines offer no precise formula for judgment and they necessitate rather than avoid, careful consideration based upon the entire record." *United States* v. *Continental Can Co.*, 378 U.S. 441, 449 (1964).

Both before and after *Brown Shoe* the cases acknowledge the principle that "the boundaries of the relevant market

---

[83] As far as price differences in raw fuel are concerned, the trial court recognized that, "the choice between competing fuels depends not only on delivered price, but on such matters as relative thermal efficiencies and differences in capital costs of burning equipment as well. The costs of storing, handling, and in some instances, disposing of the fuel by-products or residue, for example, are economic factors which can make a low-cost fuel the most expensive fuel . . . . In some areas, operating considerations, such as air pollution control regulations, may require a premium priced fuel and foreclose consideration of others." (J.S. App. 28a-29a.)

[84] *Brown Shoe Co.* v. *United States*, 370 U.S. 294, 325 (1962).

must be drawn with sufficient breadth . . . to recognize competition where, in fact, competition exists." 370 U.S. at 326. See *United States* v. *Continental Can Co.*, 378 U.S. 441, 457 (1964); *United States* v. *duPont & Co.*, 351 U.S. 377, 404 (1956); *United States* v. *Connecticut Nat'l Bank, supra* note 80, ¶74,577 at 94,544; *United States* v. *Columbia Pictures Corp.*, 189 F.Supp. 153, 185 (S.D.N.Y. 1960).[85]

The Government would fault the District Court's reading of *United States* v. *Continental Can Co.*, 378 U.S. 441 (1964). (Gov't. Brief, pp. 33-35.) Chief Judge Robson, however, construed the decision (which involved only whether the Government had made out a *prima facie* case) in precisely the same manner as Justice Goldberg in his concurring opinion. That is to say, that the relevant product market was a *question of fact* in each case, and that "upon remand it will be open to the defendants not only to rebut the *prima facie* inference that metal and glass containers may be considered together as a line of commerce but also to prove that plastic or other containers in fact compete with metal and glass to such an extent that as a matter of 'competitive reality' they must be considered as part of the determinative line of commerce." 378 U.S. at 466.

What the Government really despairs of, however, is not that the District Court adopted the wrong line of commerce, but that it did not decide the "crucial" question in the litigation solely on improperly aggregated coal production statistics. As is discussed below, the court properly refused to do so and declined to view the case as a numbers game. If, for example, the Court's conclusion had focused

[85] The decision in *United States* v. *Aluminum Co. of America*, 377 U.S. 271 (1964) announces no different rule. Insulated aluminum conductor was found to be a submarket because there was not a sufficient degree of competitiveness between that product and insulated copper conductor. 377 U.S. at 276-77.

on defendant's *de minimus* share of energy markets, the Government's quarrel with the trial court's product market might have some substance. Since, however, that was decidedly not the rationale below, the Government's arguments on the line of commerce issue, and the issue itself, have no significance.

The Geographic Markets. Upon the issue of the relevant geographic market, there is and was no dispute among the parties concerning the proper legal standard: appropriate sections of the country must "correspond to the commercial realities of the industry and be economically significant." *Brown Shoe Co.* v. *United States, supra,* 370 U.S. at 336-37.[86] But while the Government claims that each of the two geographic markets it proposed "corresponds to the competitive realities of the coal industry" (Gov't. Brief, p. 37), the trial court properly decided this factual issue against them:

> "The Government's proposed geographic markets, Illinois and the Eastern Interior Coal Province, are based essentially on past and present production statistics and do not relate to actual coal consumption patterns. The Government failed to produce evidence to establish the existence of a market for coal within these two proffered geographic areas." (J.S. App. 56a.)

The evidence overwhelmingly supported these findings.[87]

---

[86] Accord: *Case-Swayne Co.* v. *Sunkist Growers, Inc.*, 369 F.2d 449, 456 (9th Cir. 1966), *rev'd on other grounds*, 389 U.S. 384 (1967); *United States* v. *Connecticut Nat'l Bank, supra,* ¶74,577 at 94,544; *United States* v. *Northwest Industries, Inc.*, 301 F.Supp. 1066, 1083-84 (N.D. Ill. 1969); *United States* v. *Tidewater Marine Service, Inc.*, 284 F.Supp. 324, 332 (E.D. La. 1968); *United States* v. *Crocker-Anglo National Bank*, 277 F.Supp. 133, 173 (N.D. Cal. 1967); and *United States* v. *Kimberly-Clark Corp.*, 264 F.Supp. 439, 457 (N.D. Cal. 1967).

[87] Significantly, the Government's Brief is searched in vain for a claim that either Illinois or the so-called Province sales area is a

The Government's failure to prove the existence of either an Illinois or an "Eastern Interior Coal Province sales area" market for coal was mainly at the hands of its own trial economist, James Folsom. On direct examination, under cross-examination, and when questioned by the court, Mr. Folsom confessed he had "problems" with the Government's suggestion of the "Province sales area" as a market—principally because of its failure to take account of the important role which transportation costs play in determining where coal from any given mine can be sold. He could also not explain why certain areas had been included within the "Province sales area" and others excluded. (Folsom A.1689-90, 1701, 1711-12.) The following examination of Mr. Folsom by Government counsel is illustrative:

> "Q. I hand you what has been received into evidence as Government's Exhibit 52, which is a chart entitled "1967 Sales of Coal in the Eastern Interior Coal Province Sales Area by Coal Producers Located in Illinois, Producing District No. 10; Indiana, Producing District No. 11; and Western Kentucky, Producing District No. 9."
>
> "I ask you to examine this exhibit, sir, and on the basis of the exhibit to tell us your opinion as to the validity of the Government's choice of the Eastern Interior Coal Province sales area as one of the relevant economic markets in this lawsuit."
>
> "A. *I do not believe that this exhibit will stand alone*—I do not believe standing alone it will justify seeing the Eastern Interior Coal Province Sales Area

"market". The Government does observe that the province constitutes a "*producing* area," that *production* figures are published for the province, that the "region is geologically united, and underlain by a coal-bearing sequence of rock," and that "Illinois has more coal resources than any other State." (Gov't. Brief, p. 38-39 and n. 22.) However, these factors hardly bear on the question of whether these areas constitute *markets*.

> as a market. It gives you some basis for this, in that the percentages of production sold within the area, production by the companies in the Eastern Interior Coal Province, is fairly substantial in terms of their sales within the area; *but you have to have the testimony from the people about the fact that they buy coal all over this area, et cetera, to justify saying this is an economic market.*" (Folsom A.1711-12.)

There was, of course, no such testimony and the court so found. (J.S. App. 65a.)[88]

Similarly, there was no evidence supporting the existence of an Illinois market for coal and the Government admitted that no industry witnesses testified to its existence. (GRF, p.188.) As the court observed (J.S. App. 56a), while Mr. Folsom had "concluded that the State of Illinois was the most appropriate market" (Folsom A.1689-90), he never explained why and could name no factor that made the state's political boundaries a meaningful measure of the relevant geographic market for coal. (*Id.* at 1697-98.)[89] Defendants did show, however, that use of Illinois as a market was particularly inappropriate since 70 percent of Freeman's Southern Illinois production was shipped out of state, and, excluding shipments to Edison, less than 38 percent of its *total* 1967 production was shipped to consumers in Illinois. *Freeman Response To Government Questionnaire.*[90]

---

[88] This presents a factual situation identical to that in *United States* v. *Crocker-Anglo Nat'l. Bank*, 277 F.Supp. 133, 170 (N.D. Calif. 1967) where the Court noted that the Government could not identify any customer in a state-wide banking market.

[89] Mr. Folsom also testified that using the Mississippi and/or Ohio Rivers (which also define the boundaries of Illinois) made no sense as dividing lines in determining a coal market. Tr. 2538-39.

[90] Indeed, even the Bureau of Mines economist who prepared the statistics used by the Government recognized that the market areas in which coal can be sold are determined by Freight Rate Districts and not by state boundaries. He testified that his statistics did not

The Government's consumption statistics with respect to Illinois and the "Province sales area" (Gov't. Brief, pp. 39, 40) also failed to support the claim that these were markets. The fact that 82 percent of the coal consumed in Illinois is produced in Illinois no more demonstrates that it is a market than the fact that 100 percent of the coal sold in the western hemisphere is produced there indicates that there is a western hemisphere coal market. While such data may indicate that the market is no larger than the area in question, it plainly provides no insight as to whether the area is itself a market.[91]

The Government does not, because it cannot, effectively deal with the fact that its proposed markets have no relation to the "actual coal consumption patterns" that are dictated by considerations of transportation cost. (J.S. App. 56a-57a.) Coal is, of course, a transportation intensive commodity. This Court has long been aware that "[a] difference of a few cents per ton in the transportation charge is normally sufficient to divert a coal contract from one mine to another." *Ayrshire Collieries Corp.* v. *United States,* 335 U.S. 573, 586 (1949). It is not surprising, then, that the District Court found the "evidence clearly indicates that transportation costs largely determine those facilities for whose business coal mines are able to compete and those

---

deal with specific markets and conceded that "anyone with even a minimum amount of knowledge of the coal industry" knows that consumers in the Fulton-Peoria area, for example, cannot be sold coal from Southern Illinois on a competitive basis. (Gallagher A. 320-22.)

[91] The shortcoming of the Government's market delineation procedure in drafting its complaint was simply that it was incomplete. Had the Government carried its own technique one step further, it would have found, as did the trial court, that the ICC-designated Freight Rate Districts in which the mines of United Electric and Freeman were located serve "separate and distinct" marketing areas. (J.S. App. 57a-59a, 62a.)

mines to which coal consumers can practicably turn for supplies." (J.S. App. 57a; see also J.S. App. 19a-20a.)[92]

Finally, the Government's argument that "there may be more than one relevant section of the country" (Gov't. Brief, p. 44) avails it nothing. Other relevant geographic markets, if there are any, still have to correspond to "commercial realities" and those urged by the Government did not. As the court observed, "[r]esponses to the subpoena questionnaire [which the District Court had ordered] sent to midwest coal consumers demonstrated that each Freight Rate District serves a distinct and definable area, as did the testimony of producers and consumers." (J.S. App. 57a.) This evidence showed that distribution patterns of coal were dictated not by political boundaries, but by transportation costs, coal quality characteristics[92a] and Freight Rate Districts. (J.S. App. 57a; Steiner A.1602-15; see, generally, DPF 283-88, A.963-65; DPF 309-45, A.970-79.)

The Government's attempt to obfuscate the "commercial realities" of actual coal distribution patterns fails. First,

---

[92] The Government's reliance (Gov't. Brief, p. 43) on *Tampa Electric Co.* v. *Nashville Coal Co.*, 365 U.S. 320 (1961), is misplaced. The fact that coal producers in a number of states might effectively compete for the business of a customer located in Florida—far removed from any coal production and thus offering no significant shipping cost advantage to producers in a single area—has absolutely no bearing on the question whether a coal producer located in one Illinois Freight Rate District can successfully compete with a producer in another Illinois Freight Rate District for customers whose location gives the latter producer a very substantial shipping cost advantage. In the present case, involving just such cost advantages, the trial court found that disadvantaged producers could not compete.

[92a] The simple fact is that coal is not, as the Government urged below, a fungible commodity which can be sold anywhere. Coal varies considerably in such characteristics as sulphur content, ash content, moisture content, ash softening temperature, BTU rating and the like. Because boiler equipment is custom-designed, such characteristics are among the important factors which determine from which mines a consumer can practicably buy coal. See gen-

such patterns are not based on rail rates alone (Gov't. Brief, pp. 45-46), but upon all relevant costs, as the opinion and evidence demonstrate. The fact that defendants' markets were not "contiguous" (Gov't. Brief, pp. 47) is of no consequence; we are aware of no legal or economic theory, and none is cited, that holds that markets must be "contiguous" if there are more than one. Further, the claim that defendants' markets were based on only one year's sales data (Gov't. Brief, p. 48) overlooks the facts that (1) the markets revealed were supported by the testimony of consumers and producers;[93] (2) the markets were also tested against sales data collected by the Government;[94] (3) the purchase of coal under long-term contracts, as well as the rigidity of transportation rates, tends to "fix" distribution patterns for years;[95] and (4) since sales data for 1965

---

erally, DPF 289-96, A.965-67. While the Government advised the trial court that "[o]ur position is that coal is coal . . .", it can only have been embarrassed when one of its own employees readily conceded during deposition that the Government itself would never "order coal without regard to its characteristics." (Compare Transcript of Pre-trial Conference of February 19, 1969, p.6 with Nix A.423-24.) Indeed, the Government's official solicitation form for coal bids specifically provides that whenever the offered coal is not in conformance with specifications it "shall be rejected as being non-responsive." (Burton Dep.Ex.1, p.6, A.Ex.1413.)

[93] Davis A.1199-1202, 1205; Sherwood A.1375; Moser A.1386, 1389, 1394; Wood A.1176-78; Tomey A.1110-12; Steele A.1266-67, 1280; Tarzy A.271-72; Hill A.1298-99, 1303, 1306; Morris A.1072-74, 1079, 1151-53; Nugent A.1517-19; Redard A.570-73; King A.403-04, 409; Beck A.431-32; Morrison A.602-04, 606-07; Abrahamson A.652-55; Petersen A.367-69, 374-75, 377-78; Nicosin A.527-28; Tarzy A.256-57, 270-71.

[94] The Government sent a questionnaire to virtually every Midwest coal producer seeking information as to the destination of all coal shipments for 1965, 1966 and 1967. Defendants checked their analysis of markets against this sales data collected by the Government for 1967. The results were essentially identical. Compare DX 55 with DX 56, A.Ex.462, 481.

[95] To illustrate, DX 57, A.Ex.506, is a chart prepared in *1960* showing utility use of coal in that year according to Freight Rate

and 1966 were available to the Government, they could easily have shown 1967 data to be unreliable if that had been the case.[96]

Finally, the Government attempts to disparage these actual coal distribution patterns by calling them a "patchwork" and a "crazy-quilt" and claiming that, while they are "purportedly" based on actual areas served, they "do not reflect the way coal is marketed." (Gov't. Brief, pp. 44, 45, 47.) This overlooks that (1) these patterns are based on the responses of virtually every significant consumer of coal in the Midwest to a subpoena questionnaire issued by the District Court in a form agreed to by the Government, and (2) the accuracy of all of this data was *stipulated* in advance of trial, including the fact that "[i]n 1967, approximately 97 percent of the production in the Fulton-Peoria Freight Rate District, 100 percent of the production in the Springfield Freight Rate District and 98 percent of the production in the Belleville Freight Rate District and 85 percent of the production in the Southern Illinois Freight Rate District, was shipped to one or more of [these]market areas . . . ." (DX 49(a), A.Ex.345; DPF 316-20, 323-27, 330-34, 337-42, A.972-78.)

In any event, the trial court's finding that "[t]he Freight Rate Districts in which the mines and reserves of United Electric are located serve separate and distinct markets from those in which the mines of Freeman are located" (J.S. App. 62a) was addressed not so much to the subsidiary legal question of the appropriate "section of the country," but to what the facts of record showed with respect to the marketing of coal. Whether it is technically correct to say that United Electric and Freeman serve separate

districts. The pattern shown in that year is virtually identical to that revealed by defendants for *1967*.

[96] See note 94, *supra*, and DPF 47-48, A.899.

markets within a "section of the country" or to say that they serve separate "sections of the country," there can be no denying that "United Electric would not and could not compete with Freeman to any substantial degree." (J.S. App. 61a.)[***]

C. The Government's Structural Data Was Not A Fair Measure Of The Competitive Impact Of The Combination.

In their post trial brief at page 8, the Government asserted that "the chief function of the market delineation is to identify an area within which sales percentages can be relied upon for substantial guidance in measuring the impact of the merger on competition." Under the factual circumstances in this case, however, and consistent with prior decisions of this Court, the District Court very properly rejected the Government's simplistic structural approach.

At the outset, it should be observed that by repeatedly referring to the question of the establishment of a *prima facie* case in connection with its structural data (Gov't. Brief, pp. 17, 51, 52, 53, 57, 58, 64), the Government confuses the true posture of the case before this Court. Unlike *United States* v. *Continental Can Co.*, 378 U.S. 441 (1964), and *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 (1966), the District Court below did not dismiss the complaint at the close of the Government's case on the ground that it had failed to carry its initial burden of proof. In contrast, the question for review here is whether the findings of the court below, after a full trial, are "clearly erroneous." *United States* v. *du Pont & Co.*, 351 U.S. 377, 381 (1956); *United States* v. *Yellow Cab Co.*, 338 U.S. 338, 342 (1949); Fed. R. Civ. P. 52(a). The Government's seeming unwillingness to

[***] See again, *United States* v. *Crocker-Anglo Nat'l Bank*, 277 F.Supp. 133, 169-73, 177-78 (N.D. Cal. 1967) (discussed at pages 51-52, *supra*).

address itself to this question—while perhaps understandable in view of the comprehensiveness of the record and the District Court's conscientious analysis of it—cannot alter that fact.

Nor is this case like *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 366 (1963), where this Court found "nothing in the record . . . to rebut the inherently anti-competitive tendency" of the merger. After two years of pre-trial discovery and a month-long trial, creating a record that included more than 10,000 pages of exhibits and more than 7,500 pages of testimony, the trial court had more than ample support for its conclusion that the Government's structural case could not be sustained.

In addition to the weakened significance of the Government's structural data brought about by aggregating such statistics in "economically unrealistic markets," (J.S. App. 65a)[96b] other key factors interdicted use of such data as an accurate measure of the competitive impact of the combination in *any* line of commerce, in *any* section of the country. These were as follows:

1. The most significant deficiency in the Government's statistical case was the total disregard of the "key factor in a coal producer's market strength—coal reserves." (J.S. App. 65a.) As we have discussed above, the level of verifiable, substantial and uncommitted coal reserves is vastly more determinative of a supplier's ability to compete than past or current production levels. An analysis of the market that takes no note, on the one hand, of United Electric's enfeebled reserve position and, on the other, of Humble's competitive importance after acquiring more than 3 billion tons of deep reserves in Illinois, just cannot be considered

---

[96b] In addition, while the Government concedes that metallurgical coal and steam coal do not compete (GRF, p.8; DX 46, p.35, A.Ex.329), its production statistics do not reflect this.

a full and accurate measure of competition in any market. The Government's statistics ignore Humble simply because it hadn't yet started production.

2. The Government's structural data was also deficient in that it failed to take into account the nature of the customers for whose business coal companies compete. Where, as here, the customers in a given market are technologically sophisticated, make it standard practice to buy only after careful investigation of the sellers, and possess the formidable bargaining power of the large-scale, long-term purchaser, production data simply cannot accurately reflect the competitive strength of the sellers in the market. Undeniably, the freedom of action possessed by sellers in such a market is totally different from that existing in a market of powerful sellers and small, weak purchasers.

The instant case thus contrasts sharply with those previously before this Court involving seller-dominated industries and markets in which the consumer wielded virtually no power. *United States* v. *Von's Grocery Co.*, 384 U.S. 270 (1966) involved the retail grocery market; *United States* v. *Pabst Brewing Co.*, 384 U.S. 546 (1966) concerned the beer market; and in *United States* v. *Philadelphia National Bank*, 374 U.S. 321, 369-370 (1963), this Court was concerned with the small businessman's lack of power in the commercial banking market. In the markets in which the defendants in the present case compete, on the other hand, tremendous power is wielded by customers.

3. The Government's production statistics suffered from the further deficiency of ignoring the pervasive changes that have occurred in the coal industry over the past quarter century. As the trial court stated in the course of its in-depth analysis:

> "The effect of the changes since World War II in the patterns of coal consumption and marketing, in labor costs, in mining technology, in productivity, in coal preparation procedures and in transportation costs has been to enhance the economies of scale production and to greatly increase capital requirements. This, in turn, has led to an increase in the size of mines." (J.S. App. 16a.)
>
> "[T]he innovations in the coal industry that have made coal prices competitive with other forms of energy have created the need for large scale production and, thus, for large companies. Experts for both the Government and the defendants agreed that under these circumstances, increase in the size of coal mining companies and the concentration of more production in fewer mines, as well as more output of a given mine devoted to a particular source, have been economically inevitable." (J.S. App. 24a.)

In recent years, the coal industry has lost to other fuels its transportation market, its spaceheating market, and its dominant position in the industrial markets; the utility market has emerged as the principal market for coal. (J.S. App. 11a-12a.) As we have discussed above, in order to compete successfully for utility customers under the long-term contractual arrangement that is now generally required, successful coal producers have necessarily grown in size.

Both the defendants' and the Government's economic experts agreed that it was the disappearance of domestic and railroad markets, as a direct result of interfuel competition, coupled with the rise of long-term contracts, that was responsible for the withdrawal and disappearance of smaller coal producers. (Steiner A.1576, 1619-20; Folsom A.1706.) As the court found, from the testimony of a number of witnesses, "small producers are, for all practical pur-

poses, in a 'different business.'" (J.S. App. 17a and n.18; see, generally, DPF 159-64, A.928-30.)

Moreover, the evidence showed that apart from the activities of Peabody Coal Company there was no trend toward concentration. It was seen that, excluding Peabody, the production shares of the two, four, and ten largest producers had, since 1959, remained stable or declined,[97] and that the United Electric-Freeman combination "accounted for less of the coal produced in Illinois and the three-state area in 1967 than it did in 1959." (J.S.App. 60a.) Whether or not the Government is correct in its assertion that "the effects of an increasingly concentrated market structure are not mitigated merely because the increases are caused chiefly by a single company" (Gov't. Brief p. 56), the assertion is irrelevent; the Government's consent decree with that single company (Peabody) has cured and nullified those effects to the Government's satisfaction. As for the future, deconcentration will continue as Humble Oil opens a mine with an output of 3 million tons per year and Peabody divests itself of an operation annually producing 6 million tons. Furthermore, the Government will surely prosecute and prevent any truly anticompetitive coal or interfuel merger.

4. Finally, the inadequacy of the Government's structural approach to the case at bar was further demonstrated by the Government's action during the negotiating of the consent decree in the *Peabody* case. The Antitrust Division went on record there (DX 37, A.Ex.264) that it would approve "without reservation" a merger of the Midland operation (which Peabody had consented to sell) and Zeigler Coal and Coke Company. This combination would have been structurally indistinguishable from United Electric-Freeman, with the resulting combination in either situation constitut-

[97] GX 64, A.Ex.83; GX 72, A.Ex.91; GX 77, A.Ex.96; GX 85, A.Ex.98; DX 237, A.Ex.1274; Steiner A.1615-21.

ing the second largest coal producer in Illinois and the Midwest. The Government's willingness to approve a Zeigler-Midland merger "without reservation" casts doubt on both the seriousness and the substance of its contention that anti-competitive effects will follow from a continuation of the United Electric-Freeman affiliation. Significantly, when he was asked to make a competitive assessment of Zeigler-Midland following a simplistic structural approach, the Government's economist at trial balked, stating, "I would still want more information. I would still want to look further." (Folsom A.1709).[98]

In view of all the evidence, the trial court very properly concluded that "continuation of the affiliation between United Electric and Freeman is not adverse to competition, nor would divestiture benefit competition even were this court to accept the Government's unrealistic product and geographic market definitions." (J.S. App. 65a-66a.)

III.

THE FOURTH QUESTION PRESENTED BY THE GOVERNMENT IS UNTIMELY, INCONSISTENT AND WITHOUT MERIT.

The argument developed by the Government under its fourth Question Presented (Gov't. Brief, pp. 2, 19-20, 63-

[98] As we pointed out in the Motion to Affirm, the Government cannot satisfactorily explain its inconsistent and irreconcilable actions. We have here not a case where the Government has merely taken no action on the one hand, while bringing suit on the other. Rather, it is a unique situation where the Antitrust Division has taken *affirmative* and contradictory action with respect to structurally identical mergers, approving the creation of one "without reservation" while simultaneously seeking to dissolve another that has existed for more than a decade. Recognizing the questionable nature of such action, the Chief of the Antitrust Division's Chicago office has stated on the record that he has "some sympathy with the defendants [United Electric-Freeman] in the Zeigler (cont.)

74) raises the claim that the District Court erred in not invoking this Court's teachings with respect to the "failing company" defense.[99] Preliminarily, it should be observed that the Government's apparent full retreat from its earlier request for an examination of the evidentiary support for the District Court's conclusions regarding United Electric's future, and a determination whether United Electric's potential had been "cut off" in 1959, speaks convincingly to what the trial record shows on those issues. (J.S. Questions 3 and 4 and pp. 20-24; Gov't. Brief, p. 2 n.1.)

As for the late-arriving claim that the District Court viewed United Electric's competitive viability under erroneous legal standards and at the wrong point in time, this is a contrived afterthought at odds not only with the record but with the Government's own position throughout the six years of this litigation. Indeed, all that the Government's new argument demonstrates is the desperate nature of its attempt to find *some* means, however strained and bizarre, to avoid the overwhelming record evidence showing that the challenged combination does not run afoul of Section 7.

The Government's naked assertions (Gov't. Brief, pp. 20, 70-74) that there is a deficiency in the record with respect to United Electric's condition and prospects in 1959 and 1967 are nonsense.[100] The Government's suggestion (without

---

matter." (Transcript of Pre-trial conference of October 3, 1969, p. 10, A.872.) The Zeigler-Midland affair is discussed in detail in Defendants' Proposed Findings 449-56, A.1011-14.

[99] We respectfully submit that the Government in injecting issues not presented in its Jurisdictional Statement has violated Rule 40(1)(d)(2) of this Court, and this portion of the Government's brief should properly be disregarded.

[100] Because of the last minute nature of its present argument, the Government has apparently not had time to decide whether it believes the District Court should have judged United Electric's state as of 1959 or as of 1967. (See Govt. Brief, pp. 19, 20, 71, 73.)

benefit of record citation) that, left to itself, United Electric "would have vigorously pursued a policy of obtaining additional reserves to enable it to continue its substantial business as its existing reserves were depleted" (Gov't. Brief, pp. 73-74) is a pipe dream.

As the Principal Geologist of the State of Illinois put it *in 1967*: "So intense has been the interest in the more favorably situated strippable reserves, that I do not know of any prime acreage that is not now under control." (DX 34, A.Ex.259.) This paralleled the assessment, *again in 1967*, of Paul Weir Company that "there are not available for purchase from non-operating owners a sufficient number of adjoining tracts that when assembled would amount to strippable coal reserves over 10 million tons." (DX 87, attached letter, p. 3, A.Ex.793.)

Nor was this strip reserve scarcity a recent phenomenon in 1967. To the contrary, the evidence was that *"by 1960*, there was no longer any possibility of acquiring or establishing, for transfer to coal producers, of any new economically mineable strip coal acreage in the Illinois basin of sufficient size to justify the opening of new mines." (DX 88, A.Ex.796; see also DX 87, p. 27, A.Ex.779.) That such was the situation throughout the 1960's was common knowledge. As Mr. Nugent explained *in his 1968 deposition*, the unavailability of Midwest strip reserves was known to virtually everyone in the utility, mining equipment and coal industries—"down to cub engineers who have just been in the business a couple of years." (Nugent A.62.)[101]

[101] See pages 18 to 19, *supra*. As the Government knows full well, the court's observation that there was no evidence that "reserves are *presently* available," (J.S. App.63a; emphasis, the court's) was not intended to contrast United Electric's condition and prospects at trial with those obtaining in 1959. Rather, it was responsive to the Government's speculations at trial—repeated in its Jurisdictional Statement (J.S. 23-24) and here (Gov't. Brief, pp. 10, 13, 66,

That an independent United Electric could not have acquired the strip reserves needed to prolong its competitive life is further confirmed by the unsuccessful efforts to acquire such reserves made by Amalgamated *in the 1950's* and Humble *in the 1960's*. (Dorrance A.394; Stipulated Testimony of George H. Shipley, A.848.)

Finally, United Electric's own efforts, immediately following the merger and continuing thereafter, place the question beyond doubt. Prior to 1959, United Electric had not built properly for its future. It had no "real" land department, its competitors had far better prospecting organizations, and it had taken up only 7 of more than 200 fields of coal reserves its employees had examined; some of the best of these were dropped without investigation.[102] Frank Kolbe, the company's former President, defended United Electric's coal reserve policy during this time on the basis that the company had other uses for its money and that he did not care to tie up money for coal fields that would not be mined for a long time in the future.[103]

Once control of United Electric was gained in 1959 by Freeman, United Electric made a vigorous but unsuccessful effort to purchase additional coal reserves.[104] It was

---

73)—that mining conditions have changed in the past, that they may continue to change, and that "properties which UEC has investigated in the past . . . may become economically strippable in the future." (Gov't. Post-Trial Brief, p. 141; see also Def. Post-Trial Brief, pp. 88-89.)

[103] Kolbe A.141-42, 144-45, 149-50, 179-80.

[104] See, generally, DPF 92-99, A.910-12; Ames A.1450; Thorson A.1169-70, 1261; Nugent A.66-68, 1525-27; Morris A.1162; Inman A.212-13; Camicia A.88-90, 95-97, 1357-58, 1363-64, 1368-70; Hopper A.1498-1500; DX 113, pp.4080, 4086, 4138, 4196, A.Ex.1029-30, 1032, 1035.

made clear to the company's management that all of the money necessary would be made available for their acquisition,[105] and Robert Inman, United Electric's Vice President of Operations, testified (A.211) that he had an "open book" with respect to such expenditures. In their search for additional reserves, United Electric's personnel were given extremely wide latitude and were not limited to the acquisition of reserves with a potential of immediate commercial development only. (Nugent A.70-71; Camicia A.1369.) As the Government admitted, United Electric investigated many strip-coal areas throughout Illinois, Indiana, and Kentucky, but these efforts were unsuccessful. (DPF 95-96, A.911; GRF, p. 16.) The Government also admitted that "after 1959, UEC's management sought to acquire economically recoverable reserves, *i.e.*, reserves which were merchantable and capable of making a profit." (GRF, p. 15.)

The evidence was equally clear that United Electric's inability to undertake deep mining had nothing to do with whether it had remained independent or whether that reading is taken in 1959, 1967, or any other date. Long before the merger United Electric had repeatedly stressed that strip mining was its business and that deep mining was not.[106] And witness after witness attested to the fact that United Electric would have been unable successfully to undertake deep mining.[107] As the Paul Weir Company summed up the situation: "While it is, of course, impossible to state for certain whether or not United Electric would even have attempted to undertake deep mining, it is improbable that they could have done so successfully, and, there-

[106] See pages 22 to 23, *supra*.

[107] See pages 24 to 28, *supra*.

fore, highly unlikely that they would have tried." (DX 87, pp.29-30, A.Ex.781-82.)

The trial court's opinion makes plain that its analysis of the challenged combination was not confined narrowly to the time of trial. Rather it encompassed a full review of *all* the evidence on *all* the likely competitive consequences of the Freeman-United Electric affiliation—from its inception through the trial date and beyond. As the court below summarized the results of its two-year review of the record before it:

> "The challenged combination has been in effect *since 1959*, and yet no adverse consequences with respect to competition were shown either *to have occurred* or likely to occur." (J.S. App. 64a)[108]

It is incredible that the Government would fault the District Court for a supposed failure to make more findings with respect to United Electric's 1959 and 1967 prospects. The Government's claim *in this Court* that such findings are the key to the case is in sharp contrast with its claim *in the court below* that such findings were "irrelevant."

The Government *here* criticizes the trial court, for example, for the lack of specific findings showing that United Electric had "no alternative way of preserving its existence." (Gov't. Brief, p. 70.) But *below* it urged against making such findings. It asked the trial court to reject Defendants' Proposed Finding 426 (A.1003), stating that

---

[108] Time and again the trial court specifically addressed itself to a consideration of the evidence over the years. For example, "the combination is *in its second decade without demonstrating* any of the indicia of concentration" (J.S. App. 60a); "[t]he mines and coal reserves of United Electric are, *and have been since prior to 1959*, located in different Freight Rate Districts than the mines and coal reserves of Freeman" (J.S. App. 62a); and "[t]hese companies *have been* and are now predominantly complementary in nature." (J.S. App. 61a.)

"[i]t would not be possible for [United Electric] to enter into deep mining by acquiring a small deep mining company," on the ground that these facts of record were "irrelevant." (GRF, p.218.) Similarly, Defendants' Proposed Findings 116 through 123 (A.917-18), reviewing the evidence that "during the 1950's [United Electric] recognized the need to stem its deteriorating competitive position and that a merger was the only realistic way available to achieve this," were summarily "objected to as irrelevant." (GRF, p.22.)[109]

Viewed in retrospect, the Government's newly concocted argument hardly merits consideration. Indeed, criticism of the trial court's primary concern with events in the period immediately preceding and surrounding the trial comes with particularly ill grace when one considers that these were "the years chosen by the Government for analysis." (J.S. App. 62a.) Thus, the principal focus of the complaint is on 1965 to 1967 (Complaint, ¶ 11-20, A.12-14); the Government's alleged common customer charts were confined to the years 1965-67 (GX 88-91, A.Ex.107-17); all of the Government's concentration and market share charts combined United Electric and Freeman data only in 1967 and subsequent years (GX 73, 86, A.Ex.92, 100; compare GX 71, A.Ex.90, with GX 72, A.Ex. 91; and GX 84 with GX 85, A.Ex.98); and the Government advised the trial court that its coal industry rebuttal witnesses would be called to testify as to "the *availability* of strip and underground coal reserves" and "*future* strip mining possibilities." (Gov't. Counsel, A.1355.)

---

[109] The Government neglects to mention the District Court's finding that "[t]he evidence shows that United Electric had earlier [before the 1959 combination] made unsuccessful attempts to merge with, or to acquire, other Illinois coal producers." (J.S. App. 8a n.7.)

In any event, the Government's disquisition on the "failing company" doctrine is beside the point. The facts of record with respect to United Electric's liquidating nature —whenever viewed—do not constitute, as the Government would have it, an attempt to "justify an otherwise illegal merger." (Gov't. Brief, p. 64.) United Electric was not acquired by "one of its largest competitors" (Gov't. Brief, p. 70), but by Freeman—a firm which the District Court found, on the basis of all of the evidence in this case, "would not and could not" compete with an independent United Electric to any substantial degree. (J.S. App. 61a; see also J.S. App. 65a.) In view of the vigorous competition which United Electric-Freeman faces from other coal producers and suppliers of other fuels, the essentially complementary nature of the combination, and the bargaining power of large and sophisticated utilities, it is clear that this affiliation neither has had nor can have any adverse competitive impact.

In sum, the events which decreed that United Electric would reach the end of its competitive significance in the 1960's took place long prior to that date, and the evidence since then has demonstrated beyond cavil that United Electric was not capable of being "preserved"—by anyone. Unable in the end to overcome the weight of this evidence, the Government concludes its brief by asking this Court to reverse the District Court's factual findings—not on the basis of the record—but with an incredible plea for "judicial notice." (Gov't. Brief, pp. 73-74.)

CONCLUSION

The decision below comports completely with settled principles of merger law and policy, and signals no softening of, or retreat from, established barriers to anticompetitive mergers. It merely represents "the considered judgment of an able trial judge, after patient hearing, that the Government's evidence fell short of its allegations—a not uncommon form of litigation casualty, from which the Government is no more immune than others." *United States* v. *Yellow Cab Co.*, 338 U.S. 338, 341 (1949). That judgment should be affirmed.

OCTOBER TERM, 1973

No. 72-402

UNITED STATES OF AMERICA, APPELLANT

v.

GENERAL DYNAMICS CORPORATION, THE UNITED ELECTRIC COAL COMPANIES, AND FREEMAN COAL MINING CORPORATION

ON APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

REPLY BRIEF FOR THE UNITED STATES

1. The major portion of appellees' brief (pp. 12–48) consists of a detailed factual discussion of the evidence that allegedly supports the district court's finding that the combination of the Freeman and United Electric coal companies would not substantially lessen competition. Thus, appellees discuss in detail, among other things, the evidence relating to the economic strength of electric utilities in bargaining with coal companies, the reasons why the merging companies allegedly really were not competing with each other with respect to the substantial sales they made to the same cus-

827-435—73——1

tomers, and the testimony of industry personnel that the merger would not adversely affect competition. They make no attempt, however, to refute the analysis in our opening brief that under the settled principles announced by this Court in a series of decisions over the last decade applying Section 7 of the Clayton Act, this merger is illegal because it significantly increased concentration in, and produced a firm controlling an undue percentage of, a concentrated market.

As we there explained, the concern of Congress in amending Section 7 of the Clayton Act in 1950 was to stem "what was considered to be a rising tide of economic concentration in the American economy" (*Brown Shoe Co.* v. *United States*, 370 U.S. 294, 315). The legislation was designed to block "mergers at a time when the trend to a lessening of competition in a line of commerce was still in its incipiency" (*id.* at 317). The focus of the statute was on changes in market structure that mergers produce rather than on specific competitive behavior; the purpose was "the protection of *competition*, not *competitors*" (*id.* at 320, emphasis in original). Section 7 deals "with probabilities, not certainties" (*id.* at 323) and "[t]his intense congressional concern with the trend toward concentration warrants dispensing, in certain cases, with elaborate proof of market structure, market behavior, or probable anticompetitive effects" (*United States* v. *Philadelphia National Bank*, 374 U.S. 321, 363).

The determination whether the effect of a particular merger may be substantially to lessen competition requires an examination of its impact upon the struc-

ture of the relevant markets. First, "[t]he 'area of effective competition' must be determined by reference to a product market (the 'line of commerce') and a geographic market (the 'section of the country')" (*Brown Shoe*, 370 U.S. at 324). It is only after the geographic and product markets have been properly defined that an informed judgment can be made whether the merger has the proscribed anticompetitive probability "in any line of commerce in any section of the country."[1]

"Statistics reflecting the shares of the market controlled by the industry leaders and the parties to the merger are, of course, the primary index of market power * * *" (*Brown Shoe*, 370 U.S. at 322, n. 38). "The market share which companies may control by merging is one of the most important factors to be considered when determining the probable effects of the combination on effective competition in the relevant market" (*id.* at 343, fn. omitted).

The district court here did not analyze or evaluate the probable effect of this merger on the structure of the relevant markets—coal as the product market and the Eastern Interior Coal Province sales area and the State of Illinois as the geographic markets (see our opening brief, pp. 20–50). Nor do appellees make any serious attempt to show that the district court cor-

[1] There may be situations in which the competitive impact of a merger may also be demonstrated in sections of the country which are not markets in the traditional customer-supplier sense, but which, nevertheless, are economically distinct areas within which competition occurs. See our jurisdictional statement in *United States* v. *The Connecticut National Bank, et al.*, No. 73-767. This is not such a case, however.

rectly applied the standards this Court traditionally has recognized as the proper touchstone for determining the validity of horizontal mergers.[2]

Instead, appellees argue (Br. 2) that the district court rulings on "market definition" that the government challenges "were neither critical to, nor controlling of, the decision below." This contention is directly at odds with this Court's admonitions that a proper assessment of the effect of a merger can be made "only in terms of the market affected" (*United States* v. *duPont & Co.*, 353 U.S. 586, 593), and that "the proper definition of the market is a 'necessary predicate' to an examination of the competition that may be affected by the horizontal aspects of the merger" (*Brown Shoe*, 370 U.S. at 335). The district court's failure to focus on this critical issue and to apply the many decisions of this Court that have invalidated horizontal mergers on the basis of the kind of struc-

[2] Appellees cite this Court's opinion in *United States* v. *Pabst Brewing Co.*, 384 U.S. 546, for the proposition that market definition may be here ignored. The issue in that case, however, was whether it was essential for the government to delineate a section of the country "by metes and bounds as a surveyor would lay off a plot of ground" (384 U.S. at 549, fn. omitted). The Court held it was enough to prove that "the merger may have a substantial anticompetitive effect somewhere in the United States—'in *any* section' of the United States" (*ibid.*; emphasis in original). Proof of the precise boundaries of the geographic market was held to be "entirely subsidiary to the crucial question in this and every § 7 case which is whether a merger may substantially lessen competition *anywhere* in the United States" (*id.* at 550; emphasis added). There is no implication that market definition may be dispensed with, only that metes and bounds precision is unnecessary.

tural analysis presented in our opening brief invalidates its conclusion that this merger did not have the anticompetitive effects proscribed by Section 7.

2. Appellees suggest, however (Br. 64–65), that this Court's decisions establish only that a merger producing such anticompetitive changes in market structure is *prima facie* illegal, and they contend that the district court's findings refute any *prima facie* illegality the government has shown.[3] To the extent that this argument stems from the claim that, at the time of the acquisition, United Electric's resources were so inadequate that it was no longer a viable entity and hence not a significant competitive factor in the market, we have answered it in our opening brief (pp. 63–74; see, also, point 3, *infra*). Implicit in appellees' contention, however, is the implication that there is something special about the coal industry that justifies a different approach and standard for determining the anticompetitive consequences of a horizontal merger of major firms. The suggestion that general antitrust principles should not be fully applied to particular industries is not novel, however (cf. *Citizen Publishing Co.* v. *United States*, 394 U.S. 131, 138,

[3] Appellees argue that this *prima facie* illegality is significant only when the district court "dismiss[es] the complaint at the close of the Government's case on the ground that it had failed to carry its initial burden of proof" (Br. 64). In *Philadelphia Bank*, itself, however, in which the theory was articulated, the government appealed from a judgment for the defendants after trial (374 U.S. at 323). The Court applied the same structural analysis in invalidating the merger in *United States* v. *Phillipsburg National Bank & Trust Co.*, 399 U.S. 350, where the district court had upheld the merger after a full trial.

n. 4). This Court has rejected such arguments before and should do so in this case.[4]

3. Appellees argue that the inadequate resources argument made in our opening brief (pp. 63–74) (1) was not made in our Jurisdictional Statement (Br. 2, 70, n. 99) and (2) is inconsistent with our position in the district court (Br. 74–75). The first of these claims is answered in our principal brief (p. 70, n. 47). The second is incorrect.

The government argued in its post-trial brief in the district court (p. 143) that United Electric's "inability to acquire additional coal reserves * * * is not a ground for approving an otherwise anticompetitive merger." More particularly, we urged there, as we do here (p. 144):

> The argument that the lack of reserves lessens future anticompetitive effect and therefore justifies the merger infers that [United Electric] is an *in futuro* wasting asset "failing company," entitled to the benefits of the failing company doctrine.

We urged that appellees had failed to satisfy the requirements of such a defense (pp. 143–146).

---

[4] In *United States* v. *Aluminum Company of America*, 377 U.S. 271, the appellees contended that the increases in concentration which the merger there produced were not sufficient to establish anticompetitive effect because of other countervailing market conditions. Brief for appellees, No. 204, O.T. 1963, pp. 49–51. This Court, however, held the merger invalid because of its change in the structure of the market: it increased Alcoa's share of the aluminum conductor market by 1.3 percent.

See, also, the argument of the Comptroller of the Currency at pages 35–39 of his brief in *United States* v. *Phillipsburg National Bank & Trust Co.*, 399 U.S. 350, No. 1093, O.T. 1969.

Similarly, our proposed conclusions of law included the following (p. 7; emphasis added):

> The United Electric Coal Companies' limited coal reserve position, *whether considered at the time of its merger into defendant General Dynamics* [1967], *or at the time it became controlled by defendant General Dynamics* through its subsidiary, defendant Freeman Coal Mining Corporation [1959], is not a defense to an otherwise unlawful merger of the United Electric Coal Companies into defendant General Dynamics Corporation. [Citing, *inter alia, Citizen Publishing Co.* v. *United States*, 394 U.S. 131.]

Appellees argued in response, as they argue here, that they were not required to meet the general standards for a failing company defense (post-trial brief, pp. 81–82). Indeed, their brief expressly acknowledged "the government's reliance * * * on cases concerning financially failing companies" (*id.* at 82).

Earlier in the proceeding, during the deposition of the appellees' expert, Professor Steiner, government counsel raised the issue. Among the questions he asked Professor Steiner were the following (A. 809):

"Directing your attention to that time, Professor, in your opinion was United Electric a firm which was heading inevitably in the direction of bankruptcy, with the grave probability that failure would ensue, that is, that the trend was irreversible?

* * * * *

"And Professor, is it your opinion that at the time in question, November of 1966, there were available to United Electric no reasonable, possible distinguishable or feasible alternatives which would have permitted

United Electric to remain an independent competitive factor within the bituminous coal industry?"

This is not a "newly concocted argument" (Br. 75). Our position in the district court was essentially the same as it is here: whether United Electric had ceased to be a significant factor in the coal business because of its allegedly inadequate reserves is a defense to be tested by the same standards applied under the failing company defense, and the critical time is when the acquisition took place (either 1959 or 1967).[8]

NOVEMBER 1973.

[8] Appellees point to a single finding of the district court that covers the period from 1959 to the present (Br. 74), but that finding does not bear on whether United Electric's reserves were at that time so depleted that it faced the imminent prospect of going out of business. Appellees also refer to some evidence in the record relating to the availability of strip reserves during the 1960's (Br. 71–74), but there is nothing to suggest that United Electric was about to cease operation or that there was no alternative means of rehabilitation short of merger with one of its largest competitors.

U.S. GOVERNMENT PRINTING OFFICE: 1973

UNITED STATES *v.* GENERAL DYNAMICS CORP. ET AL.

APPEAL FROM THE UNITED STATES DISTRICT COURT FOR THE NORTHERN DISTRICT OF ILLINOIS

No. 72-402. Argued December 5, 1973—Decided March 19, 1974

Material Service Corp., a deep-mining coal producer, and its successor, appellee General Dynamics Corp., acquired, through stock purchases, control of appellee United Electric Coal Companies, a strip-mining coal producer. The Government brought suit alleging that this acquisition violated § 7 of the Clayton Act. The District Court found no violation on the ground, *inter alia*, that the Government's evidence—consisting principally of past production statistics showing that within certain geographic markets the coal industry was concentrated among a small number of large producers, that this concentration was increasing, and that the acquisition here would materially enlarge the acquiring company's market share and thereby contribute to the concentration trend—did not support the Government's contention that the acquisition substantially lessened competition in the production and sale of coal in either or both of two specified geographic markets. This conclusion was primarily based on a determination that United Electric's coal reserves were so low that its potential to compete with other producers in the future was far weaker than the aggregate production statistics relied on by the Government might otherwise have indicated, virtually all of United Electric's proved reserves being either depleted or already committed by long-term contracts with large customers so that its power to affect the price of coal was severely limited and steadily diminishing. *Held:*

1. While the Government's statistical showing might have been sufficient to support a finding of "undue concentration" in the absence of other considerations, the District Court was justified in finding that other pertinent factors affecting the coal industry and appellees' business mandated a conclusion that no substantial lessening of competition occurred or was threatened by the acquisition. Ample evidence showed that United Electric does not have sufficient reserves, which are a key factor in measuring

a coal producer's market strength, to make it a significant competitive force. Thus, in terms of probable future ability to compete, rather than in terms of past production on which the Government relied, the court was warranted in concluding that the merger did not violate § 7 of the Act. Pp. 494–504.

2. The District Court was justified in considering post-acquisition evidence relating to changes in the patterns and structure of the coal industry and in United Electric's reserve situation, since (unlike evidence showing only that no lessening of competition has yet occurred) the demonstration of weak coal resources necessarily implied that United Electric was not merely disinclined but unable to compete effectively for future contracts, such evidence going directly to the question whether future lessening of competition was probable. Pp. 504–506.

3. United Electric's weak reserves position, rather than establishing a "failing company" defense by showing that the company would have gone out of business but for the merger, went to the heart of the Government's statistical prima facie case and substantiated the District Court's conclusion that United Electric, even if it remained in the market, did not have sufficient reserves to compete effectively for long-term contracts, and therefore appellees' failure to meet the prerequisites of a failing-company defense did not detract from the validity of the District Court's analysis. Pp. 506–508.

4. Under the "clearly erroneous" standard of Fed. Rule Civ. Proc. 52 (a), which governs as fully on direct appeal to this Court as on review by a court of appeals, the District Court's findings and conclusions are supported by the evidence and are not clearly erroneous. P. 508.

5. The District Court found new strip reserves unavailable, and the mere possibility that United Electric could some day acquire expertise to mine deep reserves does not depreciate the validity of the conclusion that United Electric at the time of trial did not have the power to compete effectively for long-term contracts, nor does it give the production statistics relied on by the Government more significance than the District Court ascribed to them. Pp. 508–510.

341 F. Supp. 534, affirmed.

STEWART, J., delivered the opinion of the Court, in which BURGER, C. J., and BLACKMUN, POWELL, and REHNQUIST, JJ., joined. DOUG-

LAS, J., filed a dissenting opinion in which BRENNAN, WHITE, and MARSHALL, JJ., joined, *post*, p. 511.

Deputy Solicitor General Friedman argued the cause for the United States. With him on the briefs were *Solicitor General Bork*, former *Solicitor General Griswold*, *Assistant Attorney General Kauper*, *Mark L. Evans*, and *Carl D. Lawson*.

Reuben L. Hedlund argued the cause for appellees. With him on the brief were *Hammond E. Chaffetz*, *Donald G. Kempf, Jr.*, and *Albert E. Jenner, Jr.*

MR. JUSTICE STEWART delivered the opinion of the Court.

On September 22, 1967, the Government commenced this suit in the United States District Court for the Northern District of Illinois, challenging as violative of § 7 of the Clayton Act, 38 Stat. 731, as amended, 15 U. S. C. § 18, the acquisition of the stock of United Electric Coal Companies by Material Service Corp. and its successor, General Dynamics Corp. After lengthy discovery proceedings, a trial was held from March 30 to April 22, 1970, and on April 13, 1972, the District Court issued an opinion and judgment finding no violation of the Clayton Act. 341 F. Supp. 534. The Government appealed directly to this Court pursuant to the Expediting Act, 15 U. S. C. § 29, and we noted probable jurisdiction. 409 U. S. 1058.

I

At the time of the acquisition involved here, Material Service Corp. was a large midwest producer and supplier of building materials, concrete, limestone, and coal. All of its coal production was from deep-shaft mines operated by it or its affiliate, appellee Freeman Coal Mining Corp., and production from these operations

amounted to 6.9 million tons of coal in 1959 and 8.4 million tons in 1967. In 1954, Material Service began to acquire the stock of United Electric Coal Companies. United Electric at all relevant times operated only strip or open-pit mines in Illinois and Kentucky; at the time of trial in 1970 a number of its mines had closed and its operations had been reduced to four mines in Illinois and none in Kentucky.[1] In 1959, it produced 3.6 million tons of coal, and by 1967, it had increased this output to 5.7 million tons. Material Service's purchase of United Electric stock continued until 1959. At this point Material's holdings amounted to more than 34% of United Electric's outstanding shares and—all parties are now agreed on this point—Material had effective control of United Electric. The president of Freeman was elected chairman of United Electric's executive committee, and other changes in the corporate structure of United Electric were made at the behest of Material Service.

Some months after this takeover, Material Service was itself acquired by the appellee General Dynamics Corp. General Dynamics is a large diversified corporation, much of its revenues coming from sales of aircraft, communications, and marine products to Government agencies. The trial court found that its purchase of Material Service was part of a broad diversification program aimed at expanding General Dynamics into commercial, nondefense business. As a result of the purchase of Material Service, and through it, of Freeman and United Electric, General Dynamics became the Nation's fifth largest commercial coal producer. During the early 1960's General Dynamics increased its equity in United

[1] United Electric also had coal mining operations in Utah and other Western States. The Government has not contended, however, that these holdings are of any relevance in this case.

Electric by direct purchases of United Electric stock, and by 1966 it held or controlled 66.15% of United Electric's outstanding shares. In September 1966 the board of directors of General Dynamics authorized a tender offer to holders of the remaining United Electric stock. This offer was successful, and United Electric shortly thereafter became a wholly owned subsidiary of General Dynamics.

The thrust of the Government's complaint was that the acquisition of United Electric by Material Service in 1959 violated § 7 of the Clayton Act[2] because the takeover substantially lessened competition in the production and sale of coal in either or both of two geographic markets. It contended that a relevant "section of the country" within the meaning of § 7 was, alternatively, the State of Illinois or the Eastern Interior Coal Province Sales Area, the latter being one of four major coal distribution areas recognized by the coal industry and comprising Illinois and Indiana, and parts of Kentucky, Tennessee, Iowa, Minnesota, Wisconsin, and Missouri.[3]

---

[2] Section 7 of the Clayton Act reads in pertinent part as follows:

"No corporation engaged in commerce shall acquire, directly or indirectly, the whole or any part of the stock or other share capital and no corporation subject to the jurisdiction of the Federal Trade Commission shall acquire the whole or any part of the assets of another corporation engaged also in commerce, where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition, or to tend to create a monopoly."

[3] Testimony at trial indicated that the Eastern Interior Coal Province—the area of coal production upon which the Eastern Coal Province Sales Area was based—was originally named by United States Geological Survey maps of the coalfields in the United States and described one portion of a sequence of coal-bearing rock formations known geologically as the Pennsylvania System. The Sales Area of the Eastern Interior Coal Province was derived from the

At trial controversy focused on three basic issues: the propriety of coal as a "line of commerce," the definition of Illinois or the Eastern Interior Coal Province Sales Area as a relevant "section of the country," and the probability of a lessening of competition within these or any other product and geographic markets resulting from the acquisition. The District Court decided against the Government on each of these issues.

As to the relevant product market, the court found that coal faced strong and direct competition from other sources of energy such as oil, natural gas, nuclear energy, and geothermal power which created a cross-elasticity of demand among those various fuels. As a result, it concluded that coal, by itself, was not a permissible product market and that the "energy market" was the sole "line of commerce" in which anticompetitive effects could properly be canvassed.

Similarly, the District Court rejected the Government's proposed geographic markets on the ground that they were "based essentially on past and present production statistics and do not relate to actual coal consumption patterns." 341 F. Supp., at 556. The court found that a realistic geographic market should be defined in terms of transportation arteries and freight charges that determined the cost of delivered coal to purchasers and thus the competitive position of various coal producers. In particular, it found that freight rate districts, designated by the Interstate Commerce Commission for determining rail transportation rates, of which there were four in the area served by the appellee companies, were the prime determinants for the

assumption, acknowledged in the trial court's opinion, that the high costs of transporting coal—which may amount to 40% of the price of delivered coal—will inevitably give producers of coal a clear competitive advantage in sales in the immediate areas of the mines.

geographic competitive patterns among coal producers. In addition, the court concluded that two large and specialized coal consumption units were sufficiently differentiable in their coal use patterns to be included as relevant geographic areas.[4] In lieu of the State of Illinois or the Eastern Interior Coal Province Sales Area, the court accordingly found the relevant geographic market to be 10 smaller areas, comprising the two unique consumers together with four utility sales areas and four nonutility sales areas based on the ICC freight rate districts.

Finally, and, for purposes of this appeal most significantly, the District Court found that the evidence did not support the Government's contention that the 1959 acquisition of United Electric substantially lessened competition in any product or geographic market. This conclusion was based on four determinations made in the court's opinion, 341 F. Supp., at 558–559. First, the court noted that while the number of coal producers in the Eastern Interior Coal Province declined from 144 to 39 during the period of 1957–1967, this reduction "occurred not because small producers have been acquired by others, but as the inevitable result of the

[4] The trial court found that Commonwealth Edison, a large private electric utility with generation facilities in many parts of Illinois, and the Metropolitan Chicago Interstate Air Quality Control Region constituted separate and unique geographic regions. Commonwealth Edison was found to have unique attributes because of the great size of its coal consumption requirements, its distinctive distribution patterns, and its extensive commitment to air pollution programs and the development of nuclear energy. The Chicago Control Region, a congressionally designated area consisting of six counties in Illinois and two in Indiana, was distinguished from other geographic markets because of the impact of existing and anticipated air pollution regulations which would create special problems in the competition for coal sales contracts. 341 F. Supp. 534, 557.

change in the nature of demand for coal." Consequently, the court found, "this litigation presents a very different situation from that in such cases as United States v. Philadelphia National Bank, 374 U. S. 321 (1963), and United States v. Von's Grocery Co., 384 U. S. 270 (1966), where the Supreme Court was concerned with 'preventing even slight increases in concentration.' 374 U. S., at 365, n. 2." 341 F. Supp., at 558. Second, the court noted that United Electric and Freeman were "predominantly complementary in nature" since "United Electric is a strip mining company with no experience in deep mining nor likelihood of acquiring it [and] Freeman is a deep mining company with no experience or expertise in strip mining." *Ibid.* Third, the court found that if Commonwealth Edison, a large investor-owned public utility, were excluded, "none of the sales by United Electric in the period 1965 to 1967, the years chosen by the Government for analysis, would have or could have been competitive with Freeman, had the two companies been independent," because of relative distances from potential consumers and the resultant impact on relative competitive position. *Ibid.* Finally, the court found that United Electric's coal reserves were so low that its potential to compete with other coal producers in the future was far weaker than the aggregate production statistics relied on by the Government might otherwise have indicated. In particular, the court found that virtually all of United Electric's proved coal reserves were either depleted or already committed by long-term contracts with large customers, and that United Electric's power to affect the price of coal was thus severely limited and steadily diminishing. On the basis of these considerations, the court concluded: "Under these circumstances, continuation of the affiliation between United Electric and Freeman is not adverse

to competition, nor would divestiture benefit competition even were this court to accept the Government's unrealistic product and geographic market definitions." *Id.*, at 560.

II

The Government sought to prove a violation of § 7 of the Clayton Act principally through statistics showing that within certain geographic markets the coal industry was concentrated among a small number of large producers; that this concentration was increasing; and that the acquisition of United Electric would materially enlarge the market share of the acquiring company and thereby contribute to the trend toward concentration.

The concentration of the coal market in Illinois and, alternatively, in the Eastern Interior Coal Province was demonstrated by a table of the shares of the largest two, four, and 10 coal producing firms in each of these areas for both 1957 and 1967 that revealed the following: [5]

	Eastern Interior Coal Province		Illinois	
	1957	1967	1957	1967
Top 2 firms	29.6	48.6	37.8	52.9
Top 4 firms	43.0	62.9	54.5	75.2
Top 10 firms	65.5	91.4	84.0	98.0

These statistics, the Government argued, showed not only that the coal industry was concentrated among a small number of leading producers, but that the trend had been toward increasing concentration.[6] Furthermore, the un-

[5] The figures for 1967 reflect the impact on market concentration of the acquisition involved here.

[6] The figures demonstrating the degree of concentration in the two coal markets chosen by the Government were roughly comparable to those in *United States* v. *Von's Grocery Co.*, 384 U. S. 270, where

disputed fact that the number of coal-producing firms in Illinois decreased almost 73% during the period of 1957 to 1967 from 144 to 39 was claimed to be indicative of the same trend. The acquisition of United Electric by Material Service resulted in increased concentration of coal sales among the leading producers in the areas chosen by the Government, as shown by the following table: [7]

	1959			1967		
	Share of top 2 but for merger	Share of top 2 given merger	Percent increase	Share of top 2 but for merger	Share of top 2 given merger	Percent increase
Province	33.1	37.9	14.5	45.0	48.6	8.0
Illinois	36.6	44.3	22.4	44.0	52.9	20.2

Finally, the Government's statistics indicated that the acquisition increased the share of the merged company

---

the top four firms in the market controlled 24.4% of the sales, the top eight 40.9%, and the top 12 48.8%. See *id.*, at 281 (WHITE, J., concurring). See also *United States* v. *Pabst Brewing Co.*, 384 U. S. 546, 551, where the top four producers of beer in Wisconsin were found to control 47.74% of the market, and the top 10 in the Nation and the local three-state area to control 45.06% and 58.93%, respectively. The statistics in the present case appear to represent a less advanced state of concentration than those involved in *United States* v. *Aluminum Co. of America*, 377 U. S. 271, 279, where the two largest firms held 50% of the market, and the top five and the top nine controlled, respectively, 76% and 95.7%; and in *United States* v. *Philadelphia National Bank*, 374 U. S. 321, 365, where the two largest banks controlled 44% of the pre-merger market.

[7] The percentage increase in concentration asserted here was thus analogous to that found in *Von's Grocery*, *supra*, where the concentration among the top four, eight, and 12 firms was increased, respectively, by 18.0%, 7.6%, and 2.5% as a result of the merger invalidated there. In *Philadelphia Bank*, *supra*, the 34% increase in concentration in the two largest firms from 44% to 59% was found to be clearly significant. 374 U. S., at 365.

in the Illinois and Eastern Interior Coal Province coal markets by significant degrees: [8]

	Province		Illinois	
	Rank	Share (percent)	Rank	Share (percent)
1959				
Freeman	2	7.6	2	15.1
United Electric	6	4.8	5	8.1
Combined	2	12.4	1	23.2
1967				
Freeman	5	6.5	2	12.9
United Electric	9	4.4	6	8.9
Combined	2	10.9	2	21.8

In prior decisions involving horizontal mergers between competitors, this Court has found prima facie violations of § 7 of the Clayton Act from aggregate statistics of the sort relied on by the United States in this case. In *Brown Shoe Co.* v. *United States*, 370 U. S. 294, the Court reviewed the legislative history of the most recent amendments to the Act and found that "[t]he dominant theme pervading congressional consideration of the 1950 amendments was a fear of what was considered to be a rising tide of economic concentration in the American economy." *Id.*, at 315. A year later, in *United States* v. *Philadelphia National Bank*, 374 U. S. 321, the Court clarified the relevance of a statistical demonstration of concentration in a particular industry and of the effects

[8] The 1959 Illinois figure of 23.2% was asserted by the Government to be comparable to the 23.94% share of the Wisconsin beer market found to be significant in *Pabst*, *supra*, and the 25% share controlled by the merged company in *United States* v. *Continental Can Co.*, 378 U. S. 441, 461. The Province figure of 12.4% was compared with the shares held by the merged companies in *Von's Grocery* (7.5%), and in the *Pabst* national (4.49%) and three-state (11.32%) markets.

thereupon of a merger or acquisition with the following language:

> "This intense congressional concern with the trend toward concentration warrants dispensing, in certain cases, with elaborate proof of market structure, market behavior, or probable anticompetitive effects. Specifically, we think that a merger which produces a firm controlling an undue percentage share of the relevant market, and results in a significant increase in the concentration of firms in that market, is so inherently likely to lessen competition substantially that it must be enjoined in the absence of evidence clearly showing that the merger is not likely to have such anticompetitive effects." *Id.*, at 363.

See also *United States* v. *Continental Can Co.*, 378 U. S. 441, 458; *United States* v. *Von's Grocery Co.*, 384 U. S., at 277; *United States* v. *Pabst Brewing Co.*, 384 U. S. 546, 550–552.

The effect of adopting this approach to a determination of a "substantial" lessening of competition is to allow the Government to rest its case on a showing of even small increases of market share or market concentration in those industries or markets where concentration is already great or has been recently increasing, since "if concentration is already great, the importance of preventing even slight increases in concentration and so preserving the possibility of eventual deconcentration is correspondingly great." *United States* v. *Aluminum Co. of America*, 377 U. S. 271, 279, citing *United States* v. *Philadelphia National Bank*, 374 U. S., at 365 n. 42.

While the statistical showing proffered by the Government in this case, the accuracy of which was not discredited by the District Court or contested by the appellees, would under this approach have sufficed to

support a finding of "undue concentration" in the absence of other considerations, the question before us is whether the District Court was justified in finding that other pertinent factors affecting the coal industry and the business of the appellees mandated a conclusion that no substantial lessening of competition occurred or was threatened by the acquisition of United Electric. We are satisfied that the court's ultimate finding was not in error.

In *Brown Shoe* v. *United States, supra*, we cautioned that statistics concerning market share and concentration, while of great significance, were not conclusive indicators of anticompetitive effects:

> "Congress indicated plainly that a merger had to be functionally viewed, in the context of its particular industry." 370 U. S., at 321–322.
>
> "Statistics reflecting the shares of the market controlled by the industry leaders and the parties to the merger are, of course, the primary index of market power; but only a further examination of the particular market—its structure, history and probable future—can provide the appropriate setting for judging the probable anticompetitive effect of the merger." *Id.*, at 322 n. 38.

See also *United States* v. *Continental Can Co.*, 378 U. S., at 458. In this case, the District Court assessed the evidence of the "structure, history and probable future" of the coal industry, and on the basis of this assessment found no substantial probability of anticompetitive effects from the merger.

Much of the District Court's opinion was devoted to a description of the changes that have affected the coal industry since World War II. On the basis of more than three weeks of testimony and a voluminous record, the court discerned a number of clear and significant devel-

opments in the industry. First, it found that coal had become increasingly less able to compete with other sources of energy in many segments of the energy market. Following the War the industry entirely lost its largest single purchaser of coal—the railroads—and faced increasingly stiffer competition from oil and natural gas as sources of energy for industrial and residential uses. Because of these changes in consumption patterns, coal's share of the energy resources consumed in this country fell from 78.4% in 1920 to 21.4% in 1968. The court reviewed evidence attributing this decline not only to the changing relative economies of alternative fuels and to new distribution and consumption patterns, but also to more recent concern with the effect of coal use on the environment and consequent regulation of the extent and means of such coal consumption.

Second, the court found that to a growing extent since 1954, the electric utility industry has become the mainstay of coal consumption. While electric utilities consumed only 15.76% of the coal produced nationally in 1947, their share of total consumption increased every year thereafter, and in 1968 amounted to more than 59% of all the coal consumed throughout the Nation.[9]

Third, and most significantly, the court found that to an increasing degree, nearly all coal sold to utilities is transferred under long-term requirements contracts, under which coal producers promise to meet utilities' coal consumption requirements for a fixed period of time, and at predetermined prices. The court described the mutual benefits accruing to both producers and consumers of

[9] In 1968, electric utilities accounted for 59.09% of United States coal consumption, coke plants 18.20%, cement mills 1.88%, other manufacturing (including steel and rolling mills) 17.70%, and retail and miscellaneous consumers 3.14%.

coal from such long-term contracts in the following terms:

> "This major investment [in electric utility equipment] can be jeopardized by a disruption in the supply of coal. Utilities are, therefore, concerned with assuring the supply of coal to such a plant over its life. In addition, utilities desire to establish in advance, as closely as possible, what fuel costs will be for the life of the plant. For these reasons, utilities typically arrange long-term contracts for all or at least a major portion of the total fuel requirements for the life of the plant. . . .
>
> "The long-term contractual commitments are not only required from the consumer's standpoint, but are also necessary from the viewpoint of the coal supplier. Such commitments may require the development of new mining capacity. . . . Coal producers have been reluctant to invest in new mining capacity in the absence of long-term contractual commitments for the major portion of the mine's capacity. Furthermore, such long-term contractual commitments are often required before financing for the development of new capacity can be obtained by the producer." 341 F. Supp., at 543 (footnote omitted).

These developments in the patterns of coal distribution and consumption, the District Court found, have limited the amounts of coal immediately available for "spot" purchases on the open market, since "[t]he growing practice by coal producers of expanding mine capacity only to meet long-term contractual commitments and the gradual disappearance of the small truck mines has tended to limit the production capacity available for spot sales." *Ibid.*

Because of these fundamental changes in the structure of the market for coal, the District Court was justified in viewing the statistics relied on by the Government as insufficient to sustain its case. Evidence of past production does not, as a matter of logic, necessarily give a proper picture of a company's future ability to compete. In most situations, of course, the unstated assumption is that a company that has maintained a certain share of a market in the recent past will be in a position to do so in the immediate future. Thus, companies that have controlled sufficiently large shares of a concentrated market are barred from merger by § 7, not because of their past acts, but because their past performances imply an ability to continue to dominate with at least equal vigor. In markets involving groceries or beer, as in *Von's Grocery, supra,* and *Pabst, supra,* statistics involving annual sales naturally indicate the power of each company to compete in the future. Evidence of the amount of annual sales is relevant as a prediction of future competitive strength, since in most markets distribution systems and brand recognition are such significant factors that one may reasonably suppose that a company which has attracted a given number of sales will retain that competitive strength.

In the coal market, as analyzed by the District Court, however, statistical evidence of coal *production* was of considerably less significance. The bulk of the coal produced is delivered under long-term requirements contracts, and such sales thus do not represent the exercise of competitive power but rather the obligation to fulfill previously negotiated contracts at a previously fixed price. The focus of competition in a given time frame is not on the disposition of coal already produced but on the procurement of new long-term supply contracts. In this situation, a company's

past ability to produce is of limited significance, since it is in a position to offer for sale neither its past production nor the bulk of the coal it is presently capable of producing, which is typically already committed under a long-term supply contract. A more significant indicator of a company's power effectively to compete with other companies lies in the state of a company's uncommitted reserves of recoverable coal. A company with relatively large supplies of coal which are not already under contract to a consumer will have a more important influence upon competition in the contemporaneous negotiation of supply contracts than a firm with small reserves, even though the latter may presently produce a greater tonnage of coal. In a market where the availability and price for coal are set by long-term contracts rather than immediate or short-term purchases and sales, reserves rather than past production are the best measure of a company's ability to compete.

The testimony and exhibits in the District Court revealed that United Electric's coal reserve prospects were "unpromising." 341 F. Supp., at 559. United's relative position of strength in reserves was considerably weaker than its past and current ability to produce. While United ranked fifth among Illinois coal producers in terms of annual production, it was 10th in reserve holdings, and controlled less than 1% of the reserves held by coal producers in Illinois, Indiana, and western Kentucky. *Id.*, at 538. Many of the reserves held by United had already been depleted at the time of trial, forcing the closing of some of United's midwest mines.[10]

[10] The District Court found that while United Electric held six mines operating in the midwest in 1948, it had opened only three new ones since then and four had closed because of exhaustion of reserves. The court found that the evidence showed that reserves in two other mines would soon be depleted, and the appellees inform us in their briefs that these events have already occurred.

Even more significantly, the District Court found that of the 52,033,304 tons of currently mineable reserves in Illinois, Indiana, and Kentucky controlled by United, only four million tons had not already been committed under long-term contracts. United was found to be facing the future with relatively depleted resources at its disposal, and with the vast majority of those resources already committed under contracts allowing no further adjustment in price. In addition, the District Court found that "United Electric has neither the possibility of acquiring more [reserves] nor the ability to develop deep coal reserves," and thus was not in a position to increase its reserves to replace those already depleted or committed. *Id.*, at 560.

Viewed in terms of present and future reserve prospects—and thus in terms of probable future ability to compete—rather than in terms of past production, the District Court held that United Electric was a far less significant factor in the coal market than the Government contended or the production statistics seemed to indicate. While the company had been and remained a "highly profitable" and efficient producer of relatively large amounts of coal, its current and future power to compete for subsequent long-term contracts was severely limited by its scarce uncommitted resources.[11] Irrespective of the company's size when viewed as a producer, its weakness as a competitor was properly

[11] As an example of the impact of depleted or committed reserves on a company's ability to compete for long-term contracts, the District Court noted that a number of requirements contracts signed by United Electric to supply coal to electric utilities were backed up by reserves belonging to Freeman and "*could not have been obtained without that guarantee*" because of the utilities' fear that the contract obligation could not otherwise be fulfilled. 341 F. Supp., at 559 (emphasis in original).

analyzed by the District Court and fully substantiated that court's conclusion that its acquisition by Material Service would not "substantially . . . lessen competition . . . ." The validity of this conclusion is not undermined, we think, by the three-faceted attack made upon it by the Government in this Court—to which we now turn.

III

First, the Government urges that the court committed legal error by giving undue consideration to facts occurring after the effective acquisition in 1959.[12] In *FTC* v. *Consolidated Foods Corp.*, 380 U. S. 592, 598, this Court stated that post-acquisition evidence tending to diminish the probability or impact of anticompetitive effects might be considered in a § 7 case. See also *United States* v. *E. I. du Pont de Nemours & Co.*, 353 U. S. 586, 597 *et seq.*, 602 *et seq.* But in *Consolidated Foods, supra,* and in *United States* v. *Continental Can Co.*, 378 U. S., at 463, the probative value of such evidence was found to be extremely limited, and judgments against the Government were in each instance reversed in part because "too much weight" had been given to post-acquisition events. The need for such a limitation is obvious. If a demonstration that no anticompetitive effects had occurred at the time of trial or of judgment constituted a permissible defense to a § 7 divestiture suit, violators could stave off such actions

[12] The court's reliance on such facts and the absence of specific findings of fact concerning the competitive situation in 1959, at which point both sides now agree the acquisition took place, may have been engendered by the Government's apparent inconsistency in its position concerning the critical date. Certain of the appellees' proposed findings of fact concerning United Electric's resources in 1959 and its attempts to increase its depleted holdings were termed "irrelevant" by the Government at the trial.

merely by refraining from aggressive or anticompetitive behavior when such a suit was threatened or pending.[13]

Furthermore, the fact that no concrete anticompetitive symptoms have occurred does not itself imply that competition has not already been affected, "for once the two companies are united no one knows what the fate of the acquired company and its competitors would have been but for the merger." *FTC* v. *Consolidated Foods, supra,* at 598. And, most significantly, § 7 deals in "probabilities, not certainties," *Brown Shoe* v. *United States,* 370 U. S., at 323, and the mere nonoccurrence of a substantial lessening of competition in the interval between acquisition and trial does not mean that no substantial lessening will develop thereafter; the essential question remains whether the probability of such *future* impact exists at the time of trial.

---

[13] The mere nonoccurrence of anticompetitive effects from a merger would, of course, merely postpone rather than preclude a divestiture suit. This Court indicated in *United States* v. *E. I. du Pont de Nemours & Co.*, 353 U. S. 586, 597, that a merger may be attacked *ab initio* long after its culmination if effect on competition not apparent immediately after the merger subsequently appears, since § 7 was designed to arrest the creation of monopolies "'in their incipiency'" and "'incipiency' . . . denotes not the time the stock was acquired, but any time when the acquisition threatens to ripen into a prohibited effect. . . ." See also *FTC* v. *Consolidated Foods Corp.*, 380 U. S. 592, 598. The scope this "time of suit" concept gives to the Government in attacking mergers under § 7 is discussed in Orrick, The Clayton Act: Then and Now, 24 ABA Antitrust Section 44 (1964); Subcommittee on Section 7, The Backward Sweep Theory and the Oligopoly Problem, 32 ABA Antitrust L. J. 306 (1966). In the context of the present case, the "time of suit" rule coupled with the limited weight given to post-merger evidence of no anticompetitive impact tends to give the Government a "heads-I-win, tails-you-lose" advantage over a § 7 defendant: post-merger evidence showing a lessening of competition may constitute an "incipiency" on which to base a divestiture suit, but evidence showing that such lessening has not, in fact, occurred cannot be accorded "too much weight."

In this case, the District Court relied on evidence relating to changes in the patterns and structure of the coal industry and in United Electric's coal reserve situation after the time of acquisition in 1959. Such evidence could not reflect a positive decision on the part of the merged companies to deliberately but temporarily refrain from anticompetitive actions, nor could it reasonably be thought to reflect less active competition than that which might have occurred had there not been an acquisition in 1959. As the District Court convincingly found, the trend toward increased dependence on utilities as consumers of coal and toward the near-exclusive use of long-term contracts was the product of inevitable pressures on the coal industry in all parts of the country. And, unlike evidence showing only that no lessening of competition has yet occurred, the demonstration of weak coal resources necessarily and logically implied that United Electric was not merely disinclined but unable to compete effectively for future contracts. Such evidence went directly to the question of whether future lessening of competition was probable, and the District Court was fully justified in using it.

Second, the Government contends that reliance on depleted and committed resources is essentially a "failing company" defense which must meet the strict limits placed on that defense by this Court's decisions in *United States* v. *Third National Bank in Nashville*, 390 U. S. 171; *Citizen Publishing Co.* v. *United States*, 394 U. S. 131; and *United States* v. *Greater Buffalo Press*, 402 U. S. 549. The failing-company doctrine, recognized as a valid defense to a § 7 suit in *Brown Shoe*, *supra*, at 346, was first announced by this Court in *International Shoe Co.* v. *FTC*, 280 U. S. 291, and was preserved by explicit references in the legislative history of the modern amendments to § 7. H. R. Rep. No. 1191, 81st Cong., 1st Sess., 6 (1949); S. Rep. No. 1775, 81st Cong., 2d Sess.,

7 (1950). A company invoking the defense has the burden [14] of showing that its "resources [were] so depleted and the prospect of rehabilitation so remote that it faced the grave probability of a business failure . . . ," *International Shoe, supra,* at 302, and further that it tried and failed to merge with a company other than the acquiring one, *Citizen Publishing Co., supra,* at 138; *Greater Buffalo Press, supra,* at 555.

The Government asserts that United Electric was a healthy and thriving company at the time of the acquisition and could not be considered on the brink of failure, and also that the appellees have not shown that Material Service was the only available acquiring company. These considerations would be significant if the District Court had found no violation of § 7 by reason of United Electric's being a failing company, but the District Court's conclusion was not, as the Government suggests, identical with or even analogous to such a finding. The failing-company defense presupposes that the effect on competition and the "loss to [the company's] stockholders and injury to the communities where its plants were operated," *International Shoe, supra,* at 302, will be less if a company continues to exist even as a party to a merger than if it disappears entirely from the market. It is, in a sense, a "lesser of two evils" approach, in which the possible threat to competition resulting from an acquisition is deemed preferable to the adverse impact on competition and other losses if the company goes out of business.[15]

---

[14] In *Citizen Publishing Co.* v. *United States,* 394 U. S. 131, 138–139, "[t]he burden of proving that the conditions of the failing company doctrine have been satisfied" was found to be "on those who seek refuge under it." (Footnote omitted.)

[15] Alternative rationales for the failing-company defense are discussed in Bok, Section 7 of the Clayton Act and the Merging of Law and Economics, 74 Harv. L. Rev. 226, 339–347 (1960); Com-

The appellees' demonstration of United's weak reserves position, however, proved an entirely different point. Rather than showing that United would have gone out of business but for the merger with Material Service, the finding of inadequate reserves went to the heart of the Government's statistical prima facie case based on production figures and substantiated the District Court's conclusion that United Electric, even if it remained in the market, did not have sufficient reserves to compete effectively for long-term contracts. The failing-company defense is simply inapposite to this finding and the failure of the appellees to meet the prerequisites of that doctrine did not detract from the validity of the court's analysis.

Finally, the Government contends that the factual underpinning of the District Court's opinion was not supported by the evidence contained in the record, and should be re-evaluated by this Court. The findings and conclusions of the District Court are, of course, governed by the "clearly erroneous" standard of Fed. Rule Civ. Proc. 52 (a) just as fully on direct appeal to this Court as when a civil case is being reviewed by a court of appeals. The record in this case contains thousands of pages of transcript and hundreds of exhibits. Little purpose would be served by discussing in detail each of the Government's specific factual contentions. Suffice it to say that we find the controlling findings and conclusions contained in the District Court's careful and lengthy opinion to be supported by the evidence in the record and not clearly erroneous.

One factual claim by the Government, however, goes to the heart of the reasoning of the District Court and thus is worthy of explicit note here. The Government

---

ment, "Substantially to Lessen Competition . . .": Current Problems of Horizontal Mergers, 68 Yale L. J. 1627, 1662–1668 (1959).

asserts that the paucity of United Electric's coal reserves could not have the significance perceived by the District Court, since all companies engaged in extracting minerals at some point deplete their reserves and then acquire new reserves or the new technology required to extract more minerals from their existing holdings. United Electric, the Government suggests, could at any point either purchase new strip reserves or acquire the expertise to recover currently held deep reserves.

But the District Court specifically found new strip reserves not to be available: "Evidence was presented at trial by experts, by state officials, by industry witnesses and by the Government itself indicating that economically mineable strip reserves that would permit United Electric to continue operations beyond the life of its present mines are not available. The Government failed to come forward with any evidence that such reserves are *presently* available." 341 F. Supp., at 559. In addition, there was considerable testimony at trial, apparently credited by the District Court, indicating that United Electric and others had tried to find additional strip reserves not already held for coal production, and had been largely unable to do so.

Moreover, the hypothetical possibility that United Electric might in the future acquire the expertise to mine deep reserves proves nothing—or too much. As the Government pointed out in its brief and at oral argument, in recent years a number of companies with no prior experience in extracting coal have purchased coal reserves and entered the coal production business in order to diversify and complement their current operations. The mere possibility that United Electric, in common with all other companies with the inclination and the corporate treasury to do so, could some day expand into an essentially new line of business does not depreciate the validity of

the conclusion that United Electric at the time of the trial did not have the power to compete on a significant scale for the procurement of future long-term contracts, nor does it vest in the production statistics relied on by the Government more significance than ascribed to them by the District Court.

IV

In addition to contending that the District Court erred in finding that the acquisition of United Electric would not substantially lessen competition, the Government urges us to review the court's determinations of the proper product and geographic markets. The Government suggests that while the "energy market" might have been *an* appropriate "line of commerce," coal also had sufficient "practical indicia" as a separate "line of commerce" to qualify as an independent and consistent submarket. Cf. *United States* v. *Continental Can Co.*, 378 U. S., at 456–457. It also suggests that irrespective of the validity of the criteria adopted by the District Court in selecting its 10 geographic markets, competition between United Electric and Material Service within the larger alternative geographic markets claimed by the Government established those areas as a permissible "section of the country" within the meaning of § 7.

While under normal circumstances a delineation of proper geographic and product markets is a necessary precondition to assessment of the probabilities of a substantial effect on competition within them, in this case we nevertheless affirm the District Court's judgment without reaching these questions. By determining that the amount and availability of usable reserves, and not the past annual production figures relied on by the Government, were the proper indicators of future ability to compete, the District Court wholly rejected the Govern-

ment's prima facie case. Irrespective of the markets within which the acquiring and the acquired company might be viewed as competitors for purposes of this § 7 suit, the Government's statistical presentation simply did not establish that a substantial lessening of competition was likely to occur in any market. By concluding that "divestiture [would not] benefit competition even were this court to accept the Government's unrealistic product and geographic market definitions," 341 F. Supp., at 560, the District Court rendered superfluous its further determinations that the Government also erred in its choice of relevant markets. Since we agree with the District Court that the Government's reliance on production statistics in the context of this case was insufficient, it follows that the judgment before us may be affirmed without reaching the issues of geographic and product markets.

The judgment of the District Court is affirmed.

It is so ordered.

MR. JUSTICE DOUGLAS, with whom MR. JUSTICE BRENNAN, MR. JUSTICE WHITE, and MR. JUSTICE MARSHALL concur, dissenting.

In this case the United States appeals from a District Court decision [1] upholding the acquisition of stock in United Electric Coal Companies by Material Service Corp. and its successor, General Dynamics Corp., against a challenge that the acquisition violated § 7 of the Clayton Act.[2] The United States instituted this civil anti-

[1] 341 F. Supp. 534 (1972).

[2] Title 15 U. S. C. § 18 provides:

"No corporation engaged in commerce shall acquire, directly or indirectly, the whole or any part of the stock or other share capital and no corporation subject to the jurisdiction of the Federal Trade Commission shall acquire the whole or any part of the assets of

trust action on the claim that the acquisition may substantially lessen competition in the Illinois and Eastern Interior Coal Province (EICP) sales area coal markets. After trial on the merits the District Court rejected the Government's proposed product and geographic markets and dismissed the action, concluding that the Government had failed to show a substantial lessening of competition in the markets the court deemed relevant.

I

The combination here challenged is the union of two major Illinois coal producers—Freeman Coal Mining Corp. and United Electric Coal Companies—under the ultimate corporate control of General Dynamics Corp. Material Service Corp. acquired all the stock of Freeman Coal in 1942 and began to acquire United Electric stock in 1954. By 1959, holdings in United reached 34%, and Material Service requested and received representation on United's board of directors. As a result, Freeman's president was elected chairman of United's executive committee. "With the affiliation of Freeman and United Electric thus formalized in 1959, common control of the two coal companies was achieved." 341 F. Supp. 534, 537 (1972).

General Dynamics acquired Material Service Corp. in 1959 and moved to solidify the union of Freeman and United by engaging in continued purchases of United's stock throughout the early 1960's. By 1966 it held nearly two-thirds of United's outstanding shares and a successful tender offer increased the holdings to over 90%. In early 1967 United became a wholly owned subsidiary of

---

another corporation engaged also in commerce, where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition, or to tend to create a monopoly."

General Dynamics. With the 1959 union of Freeman and United Electric thus completed, the Government filed this action challenging the legality of the combination which produced in General Dynamics the Nation's fifth largest coal producer with total annual production of over 14 million tons.

II

Section 7 of the Clayton Act, the standard against which this combination must be tested, proscribes such combinations "where in any line of commerce in any section of the country, the effect of such acquisition may be substantially to lessen competition . . . ."[3] "Determination of the relevant market is a necessary predicate to a finding of a violation of the Clayton Act . . . ." *United States* v. *E. I. du Pont de Nemours & Co.*, 353 U. S. 586, 593 (1957). The court below concluded that "the energy market is the appropriate line of commerce for testing the competitive effect of the United Electric-Freeman combination." 341 F. Supp., at 555. The court rejected the Government's hypothesis of coal as a submarket for antitrust purposes as "untenable," finding that *United States* v. *Continental Can Co.*, 378 U. S. 441 (1964), "compel[s] this court to conclude that since coal competes with gas, oil, uranium and other forms of energy, the relevant line of commerce must encompass interfuel competition." 341 F. Supp., at 556.

I read *Continental Can* to import no such compulsion. That case involved the acquisition of the Nation's third largest producer of glass containers, Hazel-Atlas Glass Co., by Continental Can, the country's second largest producer of metal containers. The District Court found interindustry competition an insufficient predicate for finding a § 7 line of commerce embracing both cans and

[3] *Supra*, n. 2.

bottles. We reversed, finding that interindustry competition mandated "treating as a relevant product market the combined glass and metal container industries and all end uses for which they compete." 378 U. S., at 457 (emphasis added). But that interindustry market was only one of several lines of commerce in that case. Both parties conceded that "the can industry and the glass container industry were relevant lines of commerce." *Id.*, at 447. Since § 7 proscribes acquisitions which may involve a substantial lessening of competition in *any* line of commerce, the absence of anticompetitive effects in either the bottle or can markets could not sustain the acquisition since there existed *a* market—the glass/metal container market given recognition in this Court—in which the prohibited effect was present.

The District Court here found an energy market in which the combination did not work the prohibited effect. Whatever the correctness of that finding, *Continental Can* teaches us that it is of no help to appellees if there exist other lines of commerce in which the effect is present. Any combination may involve myriad lines of commerce; the existence of an energy market is not inconsistent with and does not negate the existence of a narrower coal market for "within this broad market, well-defined submarkets may exist which, in themselves, constitute product markets for antitrust purposes." *Brown Shoe Co.* v. *United States*, 370 U. S. 294, 325 (1962).

This principle found recognition in *Continental Can* where we recognized glass and metal containers "to be two separate lines of commerce," despite finding that competition between the lines "necessarily implied one or more *other* lines of commerce embracing both industries." 378 U. S., at 456–457 (emphasis added). It was also recognized in *United States* v. *Aluminum Co. of America*, 377 U. S. 271 (1964), which involved the com-

bination of an aluminum conductor manufacturer and a producer of both aluminum and copper conductor. The District Court there refused to treat aluminum conductor as a separate § 7 line of commerce because of the competition between aluminum and copper conductor. Though we found that competition sufficient to justify finding a single aluminum/copper conductor market, we reversed the District Court, holding that the interindustry competition did not preclude "division [of that market] for purposes of § 7 into separate submarkets." *Id.*, at 275.[4]

Coal has both price advantages and operational disadvantages which combine to delineate within the energy market "economically significant submarket[s]."[5] The consumers for whom price is determinative mark out a submarket in which coal is the overwhelming choice; the boundaries of this submarket are strengthened by coal's virtual inability to compete in other significant sectors of the energy market. Energy-use technology in highway and air transportation necessitates the use of liquid fuels. The relative operational ease of dieselized power plants has worked to virtually foreclose coal from the rail transportation market.[6] Despite their higher cost, gas and oil enjoy a competitive edge in the space-heating market because of simple consumer preference for these sources of energy over coal.[7]

The market for coal is therefore effectively limited to large industrial energy consumers such as electric utilities and certain manufacturers with the ability and economic

---

[4] Similarly, in *United States* v. *Philadelphia National Bank*, 374 U. S. 321 (1963), we held commercial banking a § 7 line of commerce even though banks compete with other institutions with respect to some services such as the making of small loans.

[5] See *Brown Shoe Co.* v. *United States*, 370 U. S. 294, 325 (1962).

[6] 341 F. Supp., at 539.

[7] *Ibid.*

incentive to consider coal as an energy source.[8] The court below noted that the "utility market has become the mainstay of coal production," 341 F. Supp., at 539, accounting for 72% of total national coal consumption in 1968. Within this sector coal's economic advantage yields it an overwhelming share of the market. In each year from 1960 to 1967 (the period during which the Freeman-United Electric union solidified) coal accounted for over 90% of the B.t.u.'s consumed by steam electric utility plants in the EICP sales area; it also provided 74% of the B.t.u.'s consumed by cement plants in the same area and 94% of the B.t.u.'s consumed by such plants in Illinois.[9]

The coal market is therefore viewed by energy consumers as a separate economic entity confined to those users with the technological capability to allow the use of coal and the incentive for economy to mandate it. Within that market coal experiences little competition from other fuels since coal's delivered price per B.t.u. in the areas served by Freeman and United Electric is significantly lower than that for any other combustible fuel except interruptible natural gas which is available only on a seasonal basis.[10] Central Illinois Light Co., for example, purchases coal at 27 cents per million B.t.u.'s,

---

[8] The only other significant use for coal is metallurgical in nature. Metallurgical coal is used as a product in the manufacture of steel. The use of such coal as a product sets it off in a separate market from nonmetallurgical coal which is used as an energy source.

[9] Although nuclear and geothermal power may draw some utility consumers from the coal market in the future, nuclear fuel is not consumable in existing fossil-fuel plants nor is nuclear fuel presently an alternative for nonutility coal consumers. Thus, whatever the future inroads of alternative fuels, there remains a significant class of energy consumers which looks only to coal.

[10] Interruptible gas is sold at a lower rate and is available only when it is not required by firm-rate customers which are supplied according to their needs and which always have priority.

firm natural gas at 45 cents, and oil (for ignition purposes) at 70 cents.[11] Since coal consumption facilities are unique and not readily adaptable to alternative energy sources, there is little interfuel price sensitivity. As the court in *Kennecott Copper Corp.* v. *FTC*, 467 F. 2d 67, 79 (CA10 1972), stated in finding that "[t]he coal industry is a distinct submarket which has characteristics which are not shared by the other fuel industries," coal prices "are now, and promise to be in the future, subject to the peculiarities of the coal business [since] other fuels appear to have a limited effect."

The competitive position of coal is thus not unlike that of aluminum conductor in *United States* v. *Aluminum Co. of America, supra.* Like coal, aluminum conductor had "little consumer acceptance" for many purposes, but its substantial price advantage over other conductors gave it "decisive advantages" in those areas of the market where price was "the single, most important, practical factor." 377 U. S., at 275–276. Despite the existence of some competition from other forms of conductor, those factors were sufficient to set aluminum conductor apart as an economically significant § 7 submarket. That precedent seems to be indistinguishable; and thus whatever the existence of a § 7 energy market, coal constitutes an economically significant submarket for § 7 purposes.[12]

III

In rejecting the Government's proposed geographic markets the court below adopted much narrower mar-

[11] Oil is used by some coal consumers for purposes to which coal is not suited such as starting up boilers or kilns.

[12] Even the court below gave some recognition to coal as a separate market in its discussion of the relevant geographic markets. The geographic markets were delineated along "the distributive patterns of . . . coal," separating out those "mines to which *coal* consumers can practicably turn for supplies." 341 F. Supp., at 556 (emphasis added).

kets which, for the most part, followed ICC freight rate districts (FRD's).[13] The justification was that, since ordinary rail rates are the same for all mines in any particular FRD and since transportation costs are the principal competitive factor in coal marketing, mines in one FRD cannot effectively compete for the same customers with mines in other FRD's. Since United Electric's mines are located in the Belleville and Fulton-Peoria FRD's and Freeman's mines are located in the Springfield and Southern Illinois FRD's, the combination of the two companies was found to present no risk of anticompetitive effects.

The error of the District Court in drawing the § 7 sections of the country "so narrowly as to place appellees in different markets"[14] is amply demonstrated by the overlapping distribution patterns of Freeman and United Electric. Though located in different FRD's and thus supposedly not competitive, they sold one-half their output to the same customers at the same facilities. Lack of competition between FRD's is further refuted by the existence of reciprocal selling patterns. For example,

---

[13] Freight rate districts are producing areas grouped for ICC rate-making purposes; all mines within each producing area are accorded the same rates to the same consuming destinations. See *Ayrshire Collieries Corp.* v. *United States*, 335 U. S. 573, 576 (1949). The other markets accepted by the District Court are Commonwealth Edison and the Metropolitan Chicago Interstate Air Quality Control Region. Commonwealth Edison was found to be unique in light of its massive coal requirements, its purchasing patterns which are "quite distinct from [those] followed by other consumers," and its singularly extensive commitment to nuclear energy. The MCIAQC, consisting of six Northeastern Illinois counties and two Northwestern Indiana counties, was found unique because of its singular access, through water and rail arteries, to almost all FRD's in the Midwest.

[14] See *United States* v. *Philadelphia National Bank*, 374 U. S., at 361.

while United's Belleville FRD mine was selling 25% of its output to customers in the Southern Illinois FRD sales area, Freeman was selling 20% of its Southern Illinois FRD coal to Belleville sales area customers.

The inability of the lower court's narrow markets to "'correspond to the commercial realities'" [15] of the distribution patterns displayed in the record is explained by the undue weight given ordinary rail rates. While transportation costs are significant, ordinary rail rates are not the single controlling element of transportation costs. First, not all rail shipments are governed by FRD rates; many of the most significant shipments are transported via "unit trains" carrying only coal from a particular producer to a particular customer pursuant to a negotiated rate. Thus Freeman ships Southern Illinois FRD coal by unit train to a Belleville FRD sales area customer at a cost *lower* than any Belleville FRD rate to that location. Second, not all coal transportation proceeds by rail. United transports most of its coal by barge, and in 1967 only one-half of all the coal sold in the five States which receive coal from Illinois was transported by all-rail shipments.

Normal rail rates are thus not so limiting as to eliminate substantial competition between FRD sales areas. Coal producers may constitute strong competitive factors in areas up to 500 miles from the mine. Thus in 1967 Freeman's Southern Illinois FRD Orient Mine shipped over 1.5 million tons of coal to customers 300 to 500 miles away. At the same time, United's Fidelity Mine, only 40 miles from the Orient, shipped more than 1 million tons, over half its total production, to equally distant locations. Both Freeman and United Electric have mines which are capable of supplying any point in the EICP sales area.

[15] See *Brown Shoe Co.* v. *United States*, 370 U. S., at 336.

Further, even assuming the existence of FRD markets, I think the court below erred in rejecting the Government's proposed markets. As with product markets, § 7 does not necessitate an anticompetitive effect in any particular geographic market; its proscription reaches combinations which may substantially lessen competition in *any* section of the country. Thus, whatever the correctness of the District Court in finding FRD markets, the lack of anticompetitive effect in those markets is of no help to General Dynamics if competition may be lessened substantially in other geographic markets. And, as with product markets, the existence of FRD markets is not inconsistent with the existence of a myriad of other sometimes overlapping markets. Thus, in *United States* v. *Pabst Brewing Co.*, 384 U. S. 546 (1966), we found Wisconsin, the Wisconsin-Michigan-Illinois tristate area, and the entire United States all to be relevant § 7 sections of the country in which to assess anticompetitive impact.

While existing sales patterns show that transportation costs are not as restrictive as the District Court found, long-range transportation costs and the national distribution of coal deposits serve to divide the country into regionally significant coal markets. Both Freeman and United Electric are located in the EICP, consisting of Central and Southern Illinois, Southwestern Indiana and Western Kentucky. The region overlies a geologically united coal-bearing rock sequence which is estimated to contain 36% of the Nation's total coal resources. Because of the separation of the region from other major producing regions,[16] EICP producers enjoy a substantial

[16] The Nation's other major coal producing regions are: (1) the Eastern Coal Province of Western Pennsylvania, West Virginia, Eastern Kentucky, and parts of Ohio, Tennessee, and Alabama; (2) the Western Interior Coal Province comprised of Central Iowa,

competitive edge with respect to sales in an area composed of Illinois, Indiana, Western Kentucky, Tennessee, Eastern Iowa, Southeastern Minnesota, Southern Wisconsin, and extreme Eastern Missouri. In 1967, 82% of EICP coal was sold in this area. Freeman sold over 93% of its coal and United Electric sold over 97% of its coal in this area.

Within the EICP sales area, Illinois stands as an economically significant submarket. In 1967, 82% of the coal consumed in Illinois came from Illinois mines and 58% of the coal mined in the State was used there. Freeman sold 42% of its coal and United Electric sold 62% of its coal to Illinois consumers, more than either company sold in any other State. Since Illinois sales are dominated by Illinois producers and since all relevant Freeman and United Electric Mines are located in Illinois,[17] the State constitutes a relevant and significant market for § 7 purposes. Although economic lines do not fall precisely along political boundaries, the Government is not required to delineate § 7 markets by "metes and bounds." *United States* v. *Pabst Brewing, supra,* at 549. In holding a four-county group a relevant geographic market in *United States* v. *Philadelphia National Bank*, 374 U. S. 321 (1963), we noted the artificiality of such political boundaries but held that "such fuzziness would seem inherent in any attempt to delineate the relevant geographic market." *Id.*, at 360 n. 37. The State of Wisconsin was held a relevant market in *Pabst Brewing, supra,* and in *United States* v. *El Paso Gas Co.*, 376 U. S. 651, 657 (1964), we held that there could be "no

Northern and Western Missouri and Eastern Oklahoma; and (3) scattered deposits in Montana, Wyoming, Colorado, and Utah. Jurisdictional Statement 5.

[17] United Electric also controls some coal deposits in Colorado and Oklahoma which are not in issue in this case. 341 F. Supp., at 538 n. 8.

doubt that California is a 'section of the country' as that phrase is used in § 7."

IV

While finding no violation of § 7 in the Freeman-United Electric combination, the District Court did not make clear the standard used in reaching that ultimate conclusion. The court did not mention what it thought to be the relevant market shares nor did it discuss the effect of the combination on industry concentration. The court merely found that Freeman and United Electric do not compete because they are located in different FRD geographic markets, and because they sell different types of coal. As already discussed, nearly all the mines of both companies are located in Southern Illinois and as demonstrated by past distribution patterns, with an ability to compete effectively at distances up to 500 miles, their presence in different minute FRD's within Southern Illinois has simply *not* rendered them noncompetitive. The differences in the types of coal sold, moreover, are irrelevant. It is true as the court below notes that United Electric sells strip-mined coal while Freeman extracts deep reserves, but the fact that the companies sold half their output to common customers demonstrates that at least a significant portion of the consuming public is understandably unconcerned with the details of extraction. While it is also true that only Freeman sells metallurgical coal and a byproduct known as dust, this says nothing more than that the companies do not compete in metallurgical coal or dust; it does not relieve the court of the responsibility for evaluating the anticompetitive effects in nonmetallurgical coal production—production which accounts for 100% of United's and 92% of Freeman's business.[18]

[18] The lack of competition from United for a mere 8% of Freeman's business is simply irrelevant. In *United States* v. *Aluminum*

The court further found that United Electric, standing alone, would not contribute meaningfully to further competition since virtually all its economically mineable strip reserves were committed under long-term contracts and it possessed neither the capability to obtain more strip reserves nor the expertise to develop its deep reserves. Although the doctrine was not invoked by name, this appears to be an application of the "failing company" defense. See *Citizen Publishing Co.* v. *United States*, 394 U. S. 131 (1969). If it is, the court proceeded on an analysis made at the wrong time and failed to discuss the legal standards employed in finding the defense to be established. The finding that 48 of United's 52 million tons of strip reserves were committed related to the time of trial. But, since the rationale of the failing-company defense is the lack of anticompetitive consequence if one of the combining companies was about to disappear from the market at any rate, the viability of the "failing company" must be assessed as of the time of the merger. *United States* v. *Greater Buffalo Press*, 402 U. S. 549, 555 (1971); *Citizen Publishing Co.* v. *United States*, *supra*, at 138.

The Court urges that United's weak reserve position, rather than establishing a failing-company defense, "went to the heart of the Government's statistical prima facie case based on production figures." Under this view United's weak reserve position at the time of trial constitutes postacquisition evidence which diminishes the possibility of anticompetitive impact and thus directly affects the strength of time-of-acquisition findings. The problem

---

Co. of America, 377 U. S. 271 (1964), we struck down a combination which affected competition in the aluminum conductor market, and that result was not affected by the irrelevant fact that one of the companies, Rome Cable, also engaged in the production of copper conductor.

with this analysis is that the District Court made no time-of-acquisition findings which such postacquisition evidence could affect. The majority concedes the obvious need for a limitation on the weight given postacquisition evidence and notes that we have reversed cases where "too much weight" has been given. Here the postacquisition events were given *all* the weight because *all* the District Court's findings were made as of the time of the trial. While findings made as of the time of the merger could concededly be tempered to a limited degree by postacquisition events, no such findings were ever made.

Many of the commitments here which reduced United's available reserves occurred after the acquisition; 21 million tons for example were committed in 1968. Similarly, though the District Court found further mineable strip reserves unavailable at the time of trial, there is no finding that they were unavailable in 1959 or 1967. To the contrary, the record demonstrates that other coal producers did acquire new strip reserves during the 1960's.[19] United's 1959 viability is further supported by the fact that it possessed 27 million tons of deep reserves. While we do not know if all these reserves were economically mineable at the time of the acquisition, there was no finding that they would not become so in the near future with advances in technology or changes in the price structure of the coal market.[20] Further there was no contention or finding that further deep reserves were not available for acquisition.[21] The District Court

[19] See Brief for United States 71.

[20] Research into new methods of extraction or a rise in the price of coal could make reserves which are uneconomical to mine at any given time economically mineable in the future.

[21] To the contrary, United Electric acquired substantial new deep reserves after the time of the acquisition since it now owns about 44 million tons of deep reserves and controls by location another 40 to 50 million tons. Reserves are controlled by location if, in

merely concluded that United had no "ability to develop deep coal reserves." [22]

While it is true that United is a strip-mining company which has not extracted deep reserves since 1954, this does not mean that United would not develop deep-mining expertise if deep reserves were all it had left or that it could not sell the reserves to some company which poses less of a threat to increased concentration in the coal market than does Freeman. United Electric was not, as the Court suggests, merely one of many companies with the possible "inclination and the corporate treasury" to allow expansion into "an essentially new line of business." United was a coal company with a thriving coal-marketing structure. At the time of the merger it had access to at least 27 million tons of deep reserves and it had operated a deep mine only five years previously. While deep-coal mining may have been an essentially new line of business for many, it was for United merely a matter of regaining the expertise it once had to extract reserves it already owned for sale in a market where it already had a good name.

---

order to be mined at all, they must be mined by those who control, by ownership, lease, or option, the contiguous reserves.

[22] If that conclusion is to lend support to the combination on the ground that United "standing alone, cannot contribute meaningfully to competition," it must be made in light of the stringent standards applicable to the failing-company defense. In *Citizen Publishing Co.* v. *United States*, 394 U. S. 131, 138–139 (1969), we said that the defense is one of "narrow scope" and that the burden of proving the defense is "on those who seek refuge under it." We also stated that the prospects of continued independent existence must be "dim or nonexistent" and that it must be established that the acquiring company is the only available purchaser. See also *United States* v. *Greater Buffalo Press*, 402 U. S. 549, 555–556 (1971), and *United States* v. *Third National Bank in Nashville*, 390 U. S. 171, 189 (1968).

V

Thus, from product and geographic markets to market-share and industry-concentration analysis to the failing-company defense, the findings below are based on legal standards which are either incorrect or not disclosed. While the court did gratuitously state that no § 7 violation would be found "even were this court to accept the Government's unrealistic product and market definitions," this conclusory statement is supported by no analysis sufficient to allow review in this Court. The majority notes that production figures are of limited significance because they include deliveries under long-term contracts entered into in prior years. It is true that uncommitted reserves or sales of previously uncommitted coal would be preferable indicia of competitive strength, but the District Court made *no* findings as to United's or Freeman's respective market shares at the time of the acquisition under either of these standards.[23]

[23] The District Court did find that, as of 1968, Freeman controlled 6.5% of the total coal reserves dedicated to existing mines in the EICP. At the same time, United Electric controlled 2.5% of that total, but almost all of this was contractually committed. If market shares are to be determined by percentage of total reserves, what is necessary is a finding as to each company's 1959 share of uncommitted Illinois and EICP reserves—including reserves which were economically mineable or which might have become so in the reasonably near future and further including an estimate as to uncontrolled reserves which might have been acquired by either company in the reasonably near future.

The District Court also found that, as of 1968, the two companies together accounted for 10.9% of the EICP coal production, and that this figure represented more than a 10% decrease from the combined production for 1959. Combined 1959 production by the companies was thus at least 12.1% of the EICP total. If market shares are to be determined by percentage of industry sales, this figure is in excess of percentages found illegal in markets with a trend toward concentration (see, *e. g.*, *United States* v. *Von's Grocery Co.*, 384 U. S. 270

On the basis of a record so devoid of findings based on correct legal standards, the judgment may not be affirmed except on a deep-seated judicial bias against § 7 of the Clayton Act. We should remand the case to the District Court with directions to assess the impact of the Freeman-United Electric combination on the Illinois and EICP sales area coal markets as of 1959.[24] We should direct the court to make findings of respective market shares, and further to evaluate United Electric's viability as an independent producer or as the possible "acquiree" of a company other than General Dynamics as of 1959, in light of the strict standards applicable to the failing-company defense. Since we abdicate our duty for responsible review and accept the mere conclusion that no § 7 violation is established on the basis of a record with none of these necessary findings, I dissent from the affirmance of the District Court's judgment.

(1966) (7.5%), and *United States* v. *Pabst Brewing Co.*, 384 U. S. 546 (1966) (4.49%)), and the court below recognized an increase in concentration in the coal market. It might be argued, however, that, if market share is to be determined by sales, the production figures found by the court below are not the relevant ones for they include production which goes to meet obligations incurred in long-term contracts entered into in prior years. In terms of competition, if sales are the relevant criteria, what is needed is a finding of "new" sales (sales of previously uncommitted coal) as a percentage of total industry new sales in Illinois and the EICP at the time of the acquisition.

[24] Common control of the two companies was achieved in 1959 and the combination was completed in 1967; at oral argument both parties conceded that the merger "took place" in 1959.
